engage in common callings. The second decision established the position that the amendments provide a federal guarantee against racial discrimination by state and not private action.

The due process clause of the 14th amendment was used in the late 19th and early 20th centuries to strike down economic legislation which did not commend itself to the social philosophy of a majority of the justices. Perhaps the high-water mark was reached in *Lochner* v. *New York* (1905), invalidating a law which limited the workday of bakers to ten hours: in time the case became less notable for the decision than for the stinging dissent of Justice Holmes. The dissenting position was definitely established as the law of the land in *Nebbia* v. *New York* (1934), a decision giving broad scope to economic legislation affecting prices, wages and hours of labour by renouncing the view that there is a closed category of businesses so affected with a public interest that for them alone is such regulation constitutionally permissible.

The New Deal program of Pres. Franklin D. Roosevelt at first foundered on restrictive constitutional decisions of the court. But the tide turned with the *National Labor Relations Board* v. *Jones and Laughlin Steel Corp.* case (1937), upholding federal authority over collective bargaining in industries in which work stoppages would affect interstate commerce. The opinion of Chief Justice Hughes was able to draw support from an earlier opinion of the same justice in the Shreveport case (1914), where federal authority over intrastate railroad rates was sustained on a showing of their effect upon competitive interstate traffic. Congressional power over industry and agriculture has been validated to an extent ample for legislative purposes. Restraints in the interest of the states have become a matter of congressional discretion rather than constitutional compulsion.

The decision in *Brown* v. *Board of Education* (1954), holding that separate but equal facilities for Negroes in public schools do not meet the constitutional standard of equal protection of the laws, created the greatest problem of compliance faced by the court since the Marshall period. But the court as an arbitral institution meanwhile won firm acceptance if not always equal understanding.

Symbolic and Pragmatic Role.—It has been argued with some force that the functions vested in the supreme court are tolerable only in a country that is agreed on its fundamental premises; that judicial review on the United States model would be impossible where there are deep philosophic cleavages; and that the U.S. practice is a corollary of the pragmatic American spirit. It can be said, however, that the relation is one of interaction. The practice of judicial review, by a reflexive effect, serves to soften the edges of ideological weapons and to promote accommodations on a working basis. The court operates in the context of specific facts; it does not so much choose between absolutes as endeavour to reach a mediating solution; and it holds itself open for reconsideration of doctrine in the light of changed circumstances and fuller experience.

By virtue of the reasoned elaboration of its opinions and the tradition of dissent it serves continually to clarify, refine and test the large philosophic ideals that are written into the constitution, and so to translate them into working principles for a federal union under a rule of law. Beyond its specific contributions, this symbolic and pragmatic function may be regarded as the most significant role of the supreme court in the life of the nation.

For the role of the United States supreme court in the development of the U.S. federal system and the history of judicial constitutional construction, *see* AMERICAN LAW and CONSTITUTION AND CONSTITUTIONAL LAW. *See* also UNITED STATES (OF AMERICA): *History;* COURT; and APPEAL.

Important decisions of the court are covered in detail in separate articles on various legal subjects of special interest, for example CIVIL LIBERTIES; CENSORSHIP; INTERSTATE COMMERCE; LABOUR LAW; and PUBLIC UTILITIES: *Regulation in the United States.*

(P. A. F.)

SURABAJA, the chief port of Java and the principal naval base of Indonesia, is situated on the northeastern coast of the island, 420 mi. (677 km.) E.S.E. of Djakarta. It lies at the western end of the Madura strait just above the Kali Mas river, one of the chief streams of the Brantas delta. The climate is humid. Pop. (1961) 666,002.

The second city in Java, Surabaja has modern houses and offices, hotels, cinemas and shops. In contrast, there are the street markets and the crowded downtown districts. The river Kali Mas is canalized, and there, as in Djakarta, the canal flows through the centre of the city. At the mouth of the river in a small park is a look-out station and from there railway and road run inland, in a southerly direction, past the old Fort Prins Hendrik (1835) to the old town, then to the upper town, and then beyond that to the suburbs of Gubeng and Wonokromo where a new residential and well-planned sector of the city has developed. In the suburb of Wonokromo, too, is Indonesia's biggest zoo.

Notable among the city's various churches is a large mosque (1868). Erlangga university has replaced the faculties of law and economics of the University of Indonesia which were formerly in Surabaja. There are also colleges for medicine and dentistry, and a naval college.

The area around the city is flat and, protected from extremes of climate by the island of Madura, is a rich agricultural region. Sugar cane is chiefly grown, but other crops include tobacco, maize and rice. Tapioca, coffee and cocoa are also produced locally. Cattle are bred and there is a large fishing fleet. The naval station is on the south side of the canal, while opposite are the commercial docks; these were destroyed by the Dutch during the Japanese invasion.

As well as being a major trading port, Surabaja is also an important industrial centre with several heavy industries. There are large railway locomotive workshops, and shipbuilding and ship-repair yards. There are textile mills and glass and cigarette factories. In the industrial suburb of Wonokromo there is an oil refinery. The bulk of Java's chief product, sugar, is shipped from Surabaja. Other goods exported include coffee, tobacco, rubber, spices and petroleum products.

Surabaja is linked with the railway system which connects the eastern and western coasts of Java and is thus in communication with Djakarta, Semarang, Jogjakarta and the other chief towns of the island. There is steamer communication with the chief ports of the world and with most of the ports of the Malay archipelago; Surabaja also lies on the main sea route from Singapore and Djakarta to Australia. From the airport at Tandjungperak, 5 mi. from the city, there are flights to various airports in the island including Djakarta and thence to the principal cities in Europe and Asia.

Surabaja was one of the chief centres of resistance to Dutch and British forces during the Indonesian war of independence which broke out in 1945 and terminated in 1949 with the transference of sovereignty to the republic of the united states of Indonesia.

SURABAJA, formerly a residency in Java, Netherlands Indies; area, 1,658 sq.mi.; bounded on the north by the residency of Bodjonegoro, on the west by that of Kediri, on the south by that of Malang, and on the east by the straits of Madura. Surabaja was one of the flattest residencies in Java, well watered by the Solo and the Brantas, and possessing a climate admirably adapted for the cultivation of sugar, the chief product, while tobacco, cassava (tapioca), maize, coffee, cocoa were grown, and the usual native crops—rice, pulses, fruit and vegetables. Cattle were bred extensively, forests in the western Rembang portion

yielding quantities of teak (there is a central lumber yard at Tjepu), and in this part too were extensive oil fields with a large refining installation of the Royal Dutch-Shell company at Tjepu. The population (1930) was 2,176,423, including 30,708 Europeans and 64,175 Chinese and other foreign Asians.

The capital was Surabaja (*q.v.*), pop. (1961) 1,007,945. Other towns were Grissee, 25 mi. N. of Surabaja (pop. [1958 est.] 35,434), a port of the old Dutch East India company and one of the first places of Dutch settlement in Java, where there was a trade in edible birds' nests; Modjokerto (pop. [1961] 51,732), a sugar industry centre, and the site of the Majapahit empire, with a museum of relics; Djombang, pop. (1958 est.) 36,855, a sugar centre; and Sidoardjo.

The main railway line from Batavia (Djakarta) crossed the residency, there were lines from Semarang to Surabaja city and thence to Pasuruan along the coast, and there was also excellent sea communication from the port of Surabaja. In 1618 the Dutch allied themselves with the Adipati of Surabaja, who favoured the Dutch against his overlord, the Sultan Ageng, and this helped to establish Dutch power in Surahaja. The residency was occupied by Japan in March 1942; it ceased to exist with the independence of Java in 1949. Surabaja regency has an area of 591 sq.mi., and a population (1961) of 666,002.

SURAJ-UD-DOWLAH (SIRAJ-UD-DAULA) (d. 1757), ruler of Bengal. The date of his birth is uncertain, but is generally placed between 1729 and 1736. His name was Mirza Mohammed, and he succeeded his grandfather Aliverdi Khan as nawab of Bengal on April 9, 1756. He was a cruel and profligate fanatic. Being offended with the English for giving protection to a native official who had escaped with treasure from Dacca, he attacked and took Calcutta on June 20, 1756. He then permitted the massacre known in history as "The Black Hole of Calcutta." (*See* CALCUTTA: *History;* and INDIA-PAKISTAN, SUBCONTINENT OF: *History.*) Calcutta was retaken by Clive and Admiral Watson on Jan. 2, 1757, and on June 23, Suraj-ud-Dowlah, routed at Plassey, fled to Rajmahal, where he was captured. He was put to death on July 4, 1757, at Murshidabad, by order of Miran, son of Mir Jafar, who had conspired against Suraj-ud-Dowlah.

SURAKARTA, a residency of the former Netherlands Indies in central Java, Indonesia; area 2,332 sq.mi., pop. (1961) 3,957,885. It is extremely hilly, except along the valley of the Solo, the principal river, which, with its tributaries, the Kaduan, etc., proved of great value to the area for agricultural purposes, watering the rich volcanic soil brought down from the mountains which flank either side of the Solo valley from north to south, and making Surakarta one of the most fertile parts of Java.

In the west the mountains are dominated by the Merbabu and Merapi groups; in the east by the Lawu group. The government of Surakarta was bounded on the north by Semarang, on the west by Kediri and Jokjakarta, on the east by Madiun, and on the south, a very small section of coast line, less than ten miles long, by the Indian ocean. Surakarta became a major tobacco-growing centre in Java; the production was concentrated mainly on estates, producing leaf tobacco.

Sugar also became an important export commodity. The sugar cane is grown extensively on the volcanic ground at the foot of the Merapi mountain. Coffee is a less important product. The government also developed the usual native cultures—rice, pulses, cassava, fruits and vegetables.

The susuhunan, or sultan of Surakarta, resided in the capital, Surakarta, pop. (1961) 367,626, also known as Solo where, too, the headquarters of the Dutch resident was established. Except in the oldest part of the town (where there is an old Dutch settlement, and Ft. Vastenburg, as well as the native quarter), there are fine, wide streets, well planned and with magnificent shade trees at their side, with many modern shops and residential buildings.

Surakarta has also a zoological garden, some very interesting houses of native nobles, and a large market.

The city is on the banks of the Solo, and also on the main railway line from Batavia (Djakarta) to Surabaja, which was built across the residency in the centre, from west to east, and served as the starting point of a line of railway to Semarang, via Gundih. Tram lines run from Surakarta south to Baturetno and west to Boyolali, the starting point for the ascent to the sanatorium of Selo, 4,500 ft., on Mt. Merapi.

The Dutch agreement of 1755 recognized two native rulers in Java, the sultan of Jogjakarta and the susuhunan of Surakarta. From about 1830 onward the native princes of Java ceased to be of any political importance.

The city and district were occupied by Japan during World War II.

See T. S. Raffles, *History of Java* (1817); M. L. van Deventer, *Daendals-Raffles* (1894). (E. E. L.; X.)

SURAT, a city and district of Gujarat state, India. There the English first established a factory on the mainland. In 1514 the Portuguese traveler Duarte Barbosa described it as an important seaport, and during the reigns of Akbar, Jahangir and Shah Jahan it rose to be the chief commercial city of India. At the end of the 16th century the Portuguese were undisputed masters of the Surat coast. But in 1612 Captain Thomas Best, and after him Captain Nicholas Downton, destroyed the Portuguese naval supremacy and made Surat the seat of a presidency under the English East India company. In 1664 Sir George Oxenden bravely defended the factory against Sivaji, but its prosperity received a fatal blow when Bombay was ceded to the company (1668) and shortly afterward made the capital of the company's possessions and the chief seat of their trade. At one time Surat's population was estimated at 800,000, but by the middle of the 19th century it had fallen to 80,000; by 1961 it had risen to 288,026. The city is on the left bank of the Tapti river, 14 mi. from its mouth, and on the Western railway, Bombay to Delhi, 157 mi. N. of Bombay. A moat and city wall divide the city proper, with its narrow streets and handsome houses, and the suburbs. The city is a centre of trade and there are cotton mills, factories for ginning and pressing cotton, rice-cleaning mills and paper, ice and soap works.

Fine cotton and silk goods are woven, and there are special manufactures of silk brocade, gold and silver wire, carpets, sandalwood and inlaid work. The ancient art of making superfine muslin, dormant since the early 19th century, was being revived in 1956. The city is the seat of three colleges of Gujarat university.

SURAT DISTRICT has an area of 4,856 sq.mi.; pop. (1961) 2,451,624. On June 10, 1948, it absorbed the former princely states of Dharampur, Bansda and Sachin, Navsari district of the former Baroda state, and other territory. It has a coast line of 80 mi., consisting of a barren stretch; behind this is a rich, highly cultivated plain, nearly 60 mi. in breadth at the mouth of the Tapti, but narrowing to only 15 mi. in the southern part, and on the northeast are the wild hills and jungle of the Dangs. Principal crops are cotton, millets, rice and pulses. The chief centres of trade are Bulsar ([1961] 37,586) and Surat. The well-built town of Navsari ([1961] 51,300), Ptolemy's *Nasaripa,* is an old Parsee settlement. Besides the main Western railway, a crossline runs eastward up the Tapti.

(The Surat Agency, a responsibility of the Bombay governor, consisted of the three states of Dharampur, Bansda and Sachin, together with the petty states of the Dangs and from 1933 was administered by the Baroda resident until absorption in Surat district in 1948.)

SURBITON, a municipal borough (1936) and parliamentary constituency of Surrey, Eng., which under the London Government Act 1963 was to be amalgamated on April 1, 1965, with Kingston-upon-Thames and Malden and Coombe to form the new London borough of Kingston upon Thames (*see* LONDON). Surbiton municipal borough is 12 mi. S.W. of Waterloo, London, with a frontage on the right bank of the Thames opposite Hampton Court park. Pop. (1961) 62,940. Area 7.4 sq.mi. It is largely residential, with some light engineering works on the Kingston bypass, and it includes Hook, Chessington (with its zoo) and Tolworth. Hillcroft college for women provides one-year residential courses in social studies and the arts and is open to foreign students speaking English. Subertone, as it was known in 1203, denotes South Barton as opposed to neighbouring Norbiton.

SURETY, in law, the party liable under a contract of guarantee (*q.v.*). In criminal practice sureties bound by recognizance are means of obtaining compliance with the order of a court of justice, to keep peace or otherwise.

See AGENCY.

SURFACE. There is no agreed definition of a surface. We may think of it as the boundary of a solid body, or as the division between two portions of space, or as the locus of an ∞^2 set of points, selected by some law from the ∞^3 points of space, and having a certain amount of continuity; in each case a plane is the simplest example; but none of these gives a precise or satisfactory definition. A very simple model illustrates the kind of difficulty that arises. If a surface partitions space, it must have two sides; but a long strip of paper, with the ends joined after one has received a half-twist, forms a surface with only one side.

At an ordinary point O of a surface, there exists a *tangent plane,* the unique limit of the plane OPQ, when the adjacent points $P,Q \to O$ by any paths lying on the surface, the angle POQ remaining finite. Any point where this limit does not exist is *singular.* The *normal* is the perpendicular to the tangent plane at its point of contact O.

A surface can also be regarded as the locus of a point satisfying a geometrical condition expressed by a single equation between its rectangular cartesian co-ordinates, say $f(x, y, z) = 0$. From this point of view, the definition of a surface depends on what types of function are admissible for f, and the question of continuity arises in another form. The surface is *analytic* if f is an analytic function, and in particular is *algebraic* if f is a polynomial. We shall use f as the name of the surface whose equation is $f = 0$.

We may also consider a surface as the locus of a curve varying according to some definite law. Thus a sphere is the locus of a meridian circle which rotates about the polar axis, or of a circle of latitude whose centre advances along the axis, while the radius first increases from zero and then decreases. Any surface can be thus regarded, for it is always the locus of its own sections by a fixed pencil of planes.

In particular, a *ruled surface* is the locus of a variable line, whose different positions are the *generators.* The tangent plane at any point on a generator contains the whole generator. Two alternative situations can arise: the plane may touch the surface all along the generator, or it may vary in a pencil (rotating about the generator) as the point of contact moves along the generator. If every generator is of the former kind, the surface is a *developable.* Such a surface has only ∞^1 tangent planes, one for each generator, whereas the general ruled (or nonruled) surface has ∞^2 tangent planes in accordance with the principle of duality. The simplest developables are cones and cylinders. Like them, any developable can be flattened out or "developed" into one plane, without tearing or stretching. Every developable that is neither a cone nor a cylinder is generated by the tangent lines of a certain twisted curve, the *edge of regression* of the surface. The tangent planes of the developable are the osculating planes of the curve. When the surface is developed into a plane, part of the plane is covered twice and part is uncovered, the edge of regression furnishing the boundary. The edge of regression may alternatively be described as the locus of the point on each generator that is closest to the "adjacent" generator. The corresponding locus on the general ruled surface is the *curve of striction* of the surface.

A surface f has ∞^3 tangent lines, each the limit of the join of two adjacent points. Except in the case of a developable, such a line is also the limiting intersection of adjacent tangent planes. To touch f imposes one condition on the ∞^4 lines of space, and f has in general ∞^2 *bitangents,* each touching it at two distinct points, and ∞^2 *inflexional tangents,* each meeting f in three adjacent points.

Order, Class, Rank.—The *order* of an algebraic surface is the degree of its equation; *i.e.*, of the polynomial f. It is the order of a plane section, and is also the number of intersections, real, coincident or imaginary, of f with any line. These are particular cases of more general properties of the order. Two surfaces of orders n, n_1 intersect in a curve of order nn_1, or in an aggregate of curves of this equivalent total order, when curves of contact and common multiple curves are counted a proper number of times. Three surfaces of orders n, n_1, n_2, have $n\,n_1\,n_2$ distinct points of intersection, or the equivalent of this when points of contact and common multiple points are properly counted.

The *class* of f is the degree of its equation regarded as an envelope, connecting the tangential co-ordinates of any one of its tangent planes. The properties of the class are dual to those of the order; it is the class of the tangent cone drawn to f from a general point, and the number of tangent planes through a general line.

The *rank* is an intermediate numerical characteristic, the number of the tangent lines that can be drawn through a given point and in a given plane through that point; it is the class of the plane section, and the order of the tangent cone.

If the polynomial f falls into rational factors $f \equiv f_1.f_2$, of degrees n_1, n_2 where $n_1 + n_2 = n$, then each factor by itself represents a distinct algebraic surface, and if a point lies on either, its co-ordinates satisfy the equation of f; regarded still as a single surface, f is *degenerate,* breaking up into the components f_1, f_2.

Polars.—The point P_λ dividing the segment PP_0 in the ratio $\lambda{:}1$ has four homogeneous co-ordinates of the form $x + \lambda x_0$. The condition that P_λ lies on f is that λ satisfies $F = 0$, where

$$F \equiv \lambda^n f_0 + \lambda^{n-1}\Delta f_0 + \cdots + \frac{\lambda^r}{(n-r)!}\Delta^{n-r} f_0 + \cdots + \frac{1}{n!}\Delta^n f_0$$

$$\equiv \frac{\lambda^n}{n!}\Delta_0{}^n f + \cdots + \frac{\lambda^r}{r!}\Delta_0{}^r f + \cdots + f,$$

and $f_0 \equiv f(x_0, y_0, z_0, w_0)$, $\Delta \equiv x\dfrac{\partial}{\partial x_0} + \text{etc.}$, $\Delta_0 \equiv x_0\dfrac{\partial}{\partial x} + \text{etc.}$

The surface $\Delta_0{}^r f$, for $r = 1, \ldots, n-1$, is the rth *polar surface* of P_0 with regard to f; the first polar passes through all the multiple points of f. In particular, $\Delta_0{}^{n-1} f$ or Δf_0 is its *polar plane,* and $\Delta^2 f_0$ its *polar quadric.* The locus of points whose polar quadrics are cones is the *Hessian* of f. Its equation of degree $4(n-2)$ expresses that the determinant of second derived functions of f vanishes.

If two roots of $F = 0$ are infinite, then P_0 lies on f, and P on the tangent plane at P_0; the two conditions are $f_0 = 0$, $\Delta f_0 = 0$. The latter represents the tangent plane at P_0, which is the polar plane of its point of contact. If P_0 is a multiple point, the tangent plane does not exist, and all the first derived functions of f vanish there.

If two roots of $F = 0$ are equal and finite, its discriminant vanishes. This equation of degree $n(n-1)^2$ in x, y, z, w is satisfied if PP_0 touches f at P; in general it represents the tangent cone from P_0 to f. Hence the class of f cannot exceed $n(n-1)^2$. It is less than this if f has multiple curves; for the condition is satisfied if P_λ is a multiple point of f, and the cone vertex P_0 standing on a multiple curve separates itself from the tangent cone.

If two roots of $F = 0$ are 0, then PP_0 touches f at P, and $f = 0$, $\Delta_0 f = 0$. The curve of contact of the tangent cone drawn from any point P_0 to f is the whole or part of the intersection of f with the first polar of P_0, any residual intersection consisting of the multiple curves of f. This curve of proper contact passes through all the isolated multiple points of f.

Indicatrix; Curvature.—In order to examine a surface in the neighbourhood of a particular point, we take this as origin O of rectangular cartesian co-ordinates, and arrange f in homogeneous functions of x, y, z, say, $f = u_0 + u_1 + \ldots + u_n$. If f consists of a single homogeneous function u_n it represents a cone vertex O of degree n. If f is general, the condition that O lies on the surface is $u_0 = 0$.

If $P\,(x, y, z)$ is a general point of space near O, at a distance small of first order, then the perpendicular distances of P from all general planes through O, viz.; x, y, z and all general linear functions of them, are small of first order. If P lies on f, the linear function u_1, being equal to $-(u_2 + \ldots + u_n)$, is small of second order; $u_1 = 0$ is the equation of the tangent plane, which in the neighbourhood of O lies infinitely closer to f than any other plane. Whenever we can safely neglect small quantities of second and higher order, the surface can be replaced by its tangent plane.

If we neglect terms of third and higher orders only, f can be

replaced by the quadric u_1+u_2, or more generally by any of the family $q\equiv u_1+u_2+u_1v_1$, where v_1 is a general linear function. These are the *osculating quadrics* of f at O, any one of which is a second approximation to the surface. The sections of f and q by any plane through O have the same curvature at O.

Let O be an ordinary point of f, with z as tangent plane, and therefore $x=y=0$ as normal. Then $f\equiv z+u_2+\ldots+u_n$, and the simplest osculating quadric is $q\equiv z+v_2$, where v_2 is the result of putting $z=0$ in u_2.

A plane $z=a$ small constant ζ, parallel and close to the tangent plane, cuts f approximately in the conic $v_2=-\zeta$, with centre on the normal, called the *indicatrix*.

If a plane through the normal meets the indicatrix in a diameter of length $2r$, the radius of curvature of the normal section is ρ, where $\frac{1}{\rho}=\frac{2\zeta}{r^2}$. An oblique plane meeting the tangent plane in the same line, and making a finite angle ϕ with the normal, cuts f in a section of radius of curvature $\rho\cos\phi$, the projection of ρ upon the plane (Meunier's theorem). This vanishes for the tangent plane, when the section is singular.

The major and minor axes of the indicatrix lie on the *principal* normal planes, making sections of maximum and minimum radii of curvature, say ρ_1, ρ_2. For a normal section inclined at an angle θ to the first principal section, $\frac{1}{\rho}=\frac{\cos^2\theta}{\rho_1}+\frac{\sin^2\theta}{\rho_2}$ (Euler's theorem).

According to the nature of the indicatrix, O is an *elliptic, hyperbolic* or *parabolic point* of f. If it is elliptic, all the normal curvatures are of the same sign, and the surface bends away from the tangent plane on one side only. The part near O of the section by $z=\zeta$ is a small real closed curve for ζ of one sign, and imaginary for ζ of the opposite sign. The section by the tangent plane $z=0$ has no real part in the neighbourhood except O itself, which is a double point with imaginary tangents. The surface is *synclastic*.

At a hyperbolic point, the surface is *anticlastic*. The principal curvatures are of opposite signs, and f bends away from the tangent plane on opposite sides in these directions. Two normal sections have inflexions, the curvatures vanishing; their planes pass through the inflexional tangents at O, which are parallel to the asymptotes of the indicatrix, and touch the section of f by the tangent plane, which has two real branches through O along which f crosses the plane. All sections near O have real branches there. If there is a line lying on f, it is one of the inflexional tangents at each of its points. *Conjugate* tangent lines are those parallel to conjugate diameters of the indicatrix.

At a parabolic point, the inflexional tangents coincide; the section by the tangent plane has a cusp. These points lie on the Hessian.

The normal at O does not in general meet the normal at an adjacent point, unless this lies on a principal section, in which case the normals intersect at one of the two *centres of curvature* of f at O. These coincide if the indicatrix is a circle; then O is an *umbilic*, all normal sections have the same curvature and all adjacent normals meet the normal at O.

Quadrics.—A surface of order 2 is a *quadric q;* in general its class and rank are each 2 also. The simplest example is the sphere (*q.v.*). Every plane section is a conic. Parallel sections are similar and similarly situated conics, whose centres lie on a line, a *diameter* of q. The diameters concur at the *centre* (which may lie at infinity), which bisects every chord of q through it. There are three mutually perpendicular planes of symmetry, the *principal planes,* intersecting by pairs in the *principal axes* which meet q in its *vertices*.

Through each point P of q there pass two generators, real or imaginary, lying wholly on q; their plane is the tangent plane to q at P, cutting q in this pair of lines. The generators fall into two systems, any one generator meeting all those of the other system and none of its own. A quadric is determined by any three generators of one system, and may be defined as the locus of a line meeting three fixed skew lines. There are six directions (only two real) of planes of circular section; the points of contact of the tangent planes parallel to these are the *umbilics*.

A quadric has three *focal conics* (two real), to each point S of which there corresponds a *directrix l,* such that the distance of any point of q from S is proportional to its distance from l measured parallel to one of the planes of circular section; S and l are focus and directrix of the section of q by the plane Sl, which is the normal plane at S to the focal conic.

A focus can also be defined as a point from which the enveloping cone is right-circular.

A quadric is fixed when its three principal sections are given; *i.e.,* it is determined by its trihedron of principal planes and the lengths of its principal axes. It depends on nine parameters. If the centre is finite, there are three main types of quadric, according to the types of the principal sections: *ellipsoid* (three ellipses), *hyperboloid of one sheet* (one ellipse, two hyperbolas), *hyperboloid of two sheets* (two hyperbolas, one section imaginary). If the centre is at infinity, one principal section is wholly at infinity; the other two are parabolas, meeting in the one finite vertex, and q is an *elliptic* or *hyperbolic paraboloid* according as these parabolas lie on the same or opposite sides of the tangent plane at the vertex. If the principal axes vanish, q is a quadric cone; if also the centre is at infinity, it is a cylinder. Finally, a degenerate quadric is a pair of intersecting, parallel or coincident planes.

The hyperboloid of one sheet and hyperbolic paraboloid have real generators, and models can be constructed by threads or wires; they are everywhere anticlastic. The ellipsoid, hyperboloid of two sheets and elliptic paraboloid have imaginary generators, and are everywhere synclastic. Referred to its principal axes, an ellipsoid of semi-axes a, b, c has the equation $\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$. An elliptic paraboloid referred to its vertex as origin can have the equation $\frac{x^2}{a^2}+\frac{y^2}{b^2}=\frac{2z}{c}$; and the other types of quadric can be represented by equally simple equations.

Cubic Surfaces.—A surface f of order 3 is of class 12, or lower if it is singular. It possesses 27 lines lying on it, of which each meets 10 others, arranged in 5 intersecting pairs. There are 45 triangles lying on f, whose planes are tritangent, touching it at the vertices. We can also select, in 36 ways, a *double-six* from the 27 lines, consisting of two sets of six lines, each line meeting five of the other set and none of its own. Any plane through a line l cuts f in a residual conic meeting l in two points, at which the plane touches f. For two positions of the plane through l, the conic touches l, at a parabolic point of f, lying on the Hessian.

There can be as many as four double points on a cubic surface. If these lie at the vertices of the tetrahedron of reference, the equation can take the form $\frac{1}{x}+\frac{1}{y}+\frac{1}{z}+\frac{1}{w}=0$. Each of the six edges of the tetrahedron absorbs four of the 27 lines, and there is one triangle of distinct lines, each meeting two opposite edges of the tetrahedron. A cubic surface can have one double line; it is then ruled, each plane through the double line meeting it in a residual generator. Two of these pass through each point of the double line, and their plane meets f in a fixed line of the surface, the simple directrix.

Singularities.—A *singular point* of a locus is one at which there is no definite, single tangent plane. If the origin O is singular, and as above $f\equiv u_0+u_1+\ldots+u_n$, the four conditions are those involved by $u_0=0$, $u_1\equiv 0$. The simplest case is the *conic node*, an ordinary double point represented by $f\equiv u_2+u_3+\ldots+u_n$, where u_2 is a general quadratic function of x, y, z, giving the proper tangent cone. Any line through O meets f in two points coinciding at O, a generator of u_2 meets it in three points, and the six *lines of closest contact* given by $u_2=u_3=0$ meet it in four. The section of f by a general plane through O has a double point with two quite distinct branches, the tangents being generators of u_2; that by a plane through a line of closest contact has an inflexion on one branch. The section by a plane touching the tangent cone

has a cusp, the two branches merging into one cycle.

If a general line through O meets f in s points there, in the simplest case O is an ordinary s-fold point with a proper tangent cone u_s, where $f \equiv u_s + u_{s+1} + \ldots + u_n$; this involves $\frac{1}{6}s(s+1)(s+2)$ conditions. Any plane through O, or any surface having O as an ordinary point, meets f in a curve having an s-fold point there. If O is s_1-fold on the second surface, the two tangent cones having no common sheet, the curve of intersection has ss_1 branches through O. If O is also s_2-fold on a third surface, the three have ss_1s_2 points of intersection absorbed at O.

If the tangent cone breaks up, the simplest case is the *binode*, a double point whose quadric tangent cone consists of two *biplanes*, intersecting in the *edge*. The section by a general plane through O has a double point as for a conic node, that by a plane through the edge has a cusp, and that by one of the biplanes has a triple point. Taking the biplanes as planes of reference, we have $u_2 = xy$; then the equation says that either x or y is small of second order, or else both are small of orders between 1 and 2. A general point of f near O is close to a definite one of the two biplanes, and, in this sense, we can speak of two sheets of f, one touched by each biplane; they are not separate sheets, but become indistinguishable near the edge $x = y = 0$. There are three lines of closest contact in each biplane; these are in general different from the edge, which meets f in three points only.

The conic node and binode are *ordinary* singularities; *i.e.*, the tangent cone, proper or degenerate, has no repeated sheet. At an *extraordinary* singularity, the tangent cone u_s not only breaks up, but has a repeated sheet, u_r say, so that $u_s \equiv u_r^2 v_{s-2r}$. The simplest case is the *unode*, a double point with a repeated tangent plane, $f = u_1^2 + u_3 + \ldots + u_n$. The surface has two connected half-sheets, the general section having a cusp. There are three lines of closest contact; the section by a plane through one of these has a tacnode, that by the tangent plane has a triple point.

A general point O of a double curve is a binode of a special kind. The two sheets of f are quite distinct; every simple point of f near O belongs definitely to one sheet or the other, the points of the double curve belonging to both. There is no continuous passage at all from one sheet to the other near O; but on the double curve there lie a certain number of *pinch-points*, unodes of a special kind (which may be absorbed in higher singularities), at which the two tangent planes coincide, and the two sheets become connected.

A *tacnode* of the surface is a double point where the general plane section has a tacnode, which is the plane singularity equivalent to two adjacent double points. Thus O has an infinite set of double points of f adjacent to it, one in every direction in the tangent plane, which may be considered as an infinitesimal double curve adjacent to O. In a similar way, a tacnodal curve is equivalent to two adjacent ordinary double curves.

In general, a singular point, whether isolated or lying on a singular curve, is characterized, first, by its multiplicity; *i.e.*, the number of intersections of f with a general line through the point that are absorbed there; next, by the nature of the tangent cone and its sheets, and of the singularity of a general section; and further by the nature and arrangement of the higher singularities of special sections. By a series of suitable transformations, any singular point or curve of a surface can be analysed into an equivalent set of component singular points and curves of standard types, and any surface can be transformed into one having only elementary singularities, and in particular into one having no isolated singular points, but only ordinary multiple curves and such points of higher singularity as necessarily lie on them; or alternatively into a surface having only a double curve and a number of triple points which are also triple for the double curve. The complete theory is complicated. Isolated singular points may give rise on transformation to singular curves; and a singular curve may give rise, from the transformation of its special points of higher singularity, to other singular curves, whose general points may be of more complicated nature (though not of higher multiplicity) than the general points of the original curve.

Singular tangent planes are defined dually to the above. Any surface of order $\geqq 3$ must have singularities of one or other kind, or of both. A surface f of order n with no singular points is of class $n' = n(n-1)^2$; a surface of class n' with no singular planes is of order $n = n'(n'-1)^2$. These two equations are incompatible unless $n = n' = 2$, in which case f is a quadric.

If f has no point singularities, it has in general two series of double and stationary tangent planes, and its reciprocal has a double and a cuspidal curve. The characteristic numbers of these modify the equations relating order and class, and make them compatible. If f has higher singularities, there exists a complicated set of relations between the numerical characteristics; the simplest are the Plücker equations for the general plane section and tangent cone.

Curves on a Surface.—The interest of f depends partly on the simpler curves lying on it. There are always its plane sections, and its curves of total intersection with other surfaces; lower curves may arise as partial intersections, components of a total intersection that breaks up through acquiring additional singularities, the cutting surface either touching f or passing through one or more of its singularities. All curves on a plane are its total intersections with cones standing on the curves. On a quadric, the conic section by a tangent plane acquires a double point at the point of contact and breaks up into a pair of generators. A cubic surface contains 27 pencils of conics, cut out by planes through the 27 lines, and many other systems of curves of orders 3, 4, and 5, cut out by quadrics containing various sets of the lines.

Other important curves on f are defined by infinitesimal properties. An *asymptotic curve* is one whose tangent at any point is one of the inflexional tangents, parallel to an asymptote of the indicatrix. A *curve of curvature* is one whose tangent at any point is a principal tangent, parallel to an axis of the indicatrix. Two curves of each of these kinds can be drawn through any general point of f. A *geodesic* is a curve whose small arcs are each the shortest distance on the surface between their extremities. On a plane, these are lines; on a developable they are curves which become lines when the surface is flattened out. An infinite number of geodesics can be drawn through a general point of f, one starting in any direction.

Families of Surfaces.—If an equation contains a parameter λ it represents a singly infinite family of surfaces; the most important case is the linear family or *pencil*, when the coefficients are linear functions of λ and the equation has the form $f + \lambda\phi = 0$. Just one member of the family passes through each general point of space. The total intersection of any two of the family is the same, being that of f, ϕ. More generally, if f, ϕ are any two algebraic surfaces, the equation of any other containing their total intersection can be expressed as $\alpha f + \beta\phi = 0$, where α, β are polynomials (Noether's theorem). In the same way, $f + \lambda\phi + \mu\psi$ gives an ∞^2 linear family or *net* of surfaces; one and only one passes through any two given points; any three surfaces of the net have the same *base*, or set of common points and curves, as f, ϕ, ψ.

If f is of order n, it has $N \equiv \frac{1}{6}(n+1)(n+2)(n+3) - 1$ independent ratios of coefficients; all such surfaces form a linear family with N degrees of freedom, and one can be made to pass through N points in general position, each of which presents one independent condition to f. Thus a quadric can be drawn through nine points, and these determine it if they are general. However, seven points determine a net of quadrics, whose base consists of eight points, viz., the seven and another, associated with and determined by the seven, which offers no independent condition; but the passage of the quadric through it is a necessary consequence of its passage through the others. Thus nine points do not determine a quadric if any eight of them are an associated set of this nature.

To have a given point as a double point imposes four conditions on f; to contain a given line, $n+1$ conditions. The number of independent conditions presented to f by an assigned element of any sort is the *postulation* of that element. The conditions for a combination of elements may force f to contain other fixed elements, or to break up. If six out of nine points lie on a plane, the only quadric containing them all consists of this plane and the plane of the other three points.

Two surfaces are *orthogonal* if at every common point the angle between them, *i.e.*, between their normals, is a right-angle. If three surfaces are mutually orthogonal, their curves of intersection are curves of curvature on each surface. If three linear families are such that the three surfaces through any point are at right angles to each other, they form an *orthogonal system; f* can form part of such a system only if it satisfies a certain differential equation of third order. In the same way, a cubic family, with three members through any point, can be an orthogonal system, *e.g.*, the confocal quadrics

$$\frac{x^2}{a^2+\lambda}+\frac{y^2}{b^2+\lambda}+\frac{z^2}{c^2+\lambda}=1,$$

where the members through a point consist of an ellipsoid, a hyperboloid of one sheet, and a hyperboloid of two sheets.

Among the infinite number of surfaces having the same boundary, *i.e.*, a given closed curve through which each is to pass, the *minimal surface* is that whose area is least. This is the form assumed by a soap film bounded by a wire in the form of the given contour. The same property must attach to any small portion of the surface, and leads to a differential equation of second order, the boundary conditions determining the arbitrary elements of the solution. A minimal surface is anticlastic everywhere. If it were synclastic at a point P, a plane near the tangent plane at P on one side would cut it in a small plane closed curve, approximately the elliptic indicatrix, whose area would be less than that of the cap on which P lies; and the total area could be reduced without affecting the given boundary.

Parametric Representation; Genus.—The co-ordinates of any point on f can be represented as functions of two parameters. We may consider x, y as the parameters, and z given as an implicit function of these by the equation $f=0$. More often it is convenient to express each co-ordinate as an explicit function of two other parameters, say $x=\phi(u,v)$, $y=\psi(u,v)$, $z=\chi(u,v)$.

In general, ϕ, ψ, χ are many-valued functions; if there are r sets of values of x, y, z for each set of u,v, and we take u,v as co-ordinates of a point of a plane, then f is represented on this plane by an $(r, 1)$ point transformation. The nature of the representation depends largely on the form of the expression for the element ds of length of arc traced on the surface, given by

$$ds^2 = dx^2+dy^2+dz^2 = Edu^2+2Fdu\,dv+Gdv^2, \text{ say,}$$

where E, F, G are certain functions of u, v. Here $E^{\frac{1}{2}}du$, $G^{\frac{1}{2}}dv$ are the elements of length along the curves represented by $v=$ const., $u=$const., at the point whose parameters are u,v; while F depends also on the angle between these curves. If they are everywhere at right-angles, *e.g.*, if they are the curves of curvature, then $F=0$.

Rational surfaces are those which can be represented on a plane by a $(1, 1)$ point transformation. Then the co-ordinates of any point on f are rational functions of two parameters, the coordinates of the corresponding point of the plane. Of the different plane representations of f, the lowest is that for which the curves in the plane corresponding to the plane sections of f are of lowest order. Any two of these have n variable intersections, corresponding to the points of f on the common line of the two planes of section; the remaining intersections are fixed, at points of the plane fundamental for the representation. An important family of curves on f are those corresponding to the lines of the plane. Any two of these have one and only one variable intersection, the remainder falling at points of f fundamental for the representation. All quadrics and cubics are rational. Surfaces of higher degree are not, unless they have a sufficient number of singular points and curves.

There are several numerical characteristics of a surface that vanish if it is rational, and may be regarded as answering to the genus of a curve. The simplest is the *genus* as defined by Noether (*Flächengeschlecht*), the number of linearly independent *adjoint* surfaces of degree $n-4$, passing $s-1$ times through every ordinary s-fold curve of f, and $s-2$ times through every ordinary isolated s-fold point, with other conditions at extraordinary singularities. It is also the number of linearly independent double integrals of the form $\iint F(x,y,z)dxdy$, where F is a rational function and x,y,z are connected by $f=0$. If f has no singularities, its genus is $\frac{1}{6}(n-1)(n-2)(n-3)$.

SURFACE HARDENING, a heat treatment of steel in which only the surface is hardened. Other surface-hardening treatments include facing, by fusing a hard metal onto a soft one, and shot peening (*see* BLAST CLEANING AND SHOT PEENING). The conventional quenching of hot steel in water or oil is literally surface hardening; however, it usually hardens not only the surface but some or all of the interior, too, depending on the size of the piece. The phrase "surface hardening" usually implies processes other than merely quenching such as carburizing, nitriding and induction hardening. The combination of a hard surface and soft interior is of inestimable value in modern engineering practices. Great strength and toughness in the core and extreme surface hardness result in a composite structure capable of withstanding certain kinds of stress to a high degree such as in gears or antifriction bearings. For less exacting requirements, low or moderate core properties and a high surface hardness can be obtained with cheaply fabricated, low-priced steels.

Carburizing.—One of the most important surface-hardening processes is carburizing in which steel is held at a high temperature (1,600° F. is common) for a long time (six hours, for instance) in a carbonaceous environment, usually a gas mixture of carbon monoxide and carbon dioxide, with or without hydrocarbons such as methane. This treatment causes carbon to diffuse into the steel to a depth of several thousandths or hundredths of an inch and leaves the carbon content of the surface much higher than that of the core; *e.g.*, 1.5% carbon compared with about .25%. When the carburized steel is quenched it becomes harder and more wear-resistant than similar steel of lower surface carbon content similarly quenched.

Carbonitriding and Cyaniding.—Carbonitriding, a variant of carburizing, is the same except that nitrogen as well as carbon diffuses into the steel. The nitrogen comes from ammonia introduced into the furnace atmosphere along with the carbonaceous gas. The cyaniding process gives a similar result; both carbon and nitrogen are supplied to the steel by diffusion from a liquid cyanide salt (usually potassium cyanide, KCN) in which the steel is immersed at about 1,600° F. Cyanides are violent poisons requiring rigid safety precautions when using the cyanide process of surface hardening.

Nitriding.—Another diffusion process producing hard surfaces is nitriding (*q.v.*) in which, by using ammonia without a carbonaceous gas, nitrogen goes into the steel and combines with other elements, principally chromium, already contained in the steel to form nitrides that are extremely hard and wear-resistant without the necessity for quenching the steel. Elimination of the quenching process is an advantage because dimensional changes that occur during quenching are avoided.

Induction Hardening.—From about 1935, another process of surface hardening has become important—induction hardening. In this process, steel is briefly heated by electrical induction so that only the surface portion has time to get hot. It is immediately cooled or quenched and the portion that was heated above the critical temperature (about 1,500° F.) becomes hard while the rest of the steel which was not heated by the brief flow of induced current remains unaffected. Induction hardening has become common in mass-production industries since World War II because it is a rapid process—heating time per piece may be five seconds or less—and because it often permits the use of a less costly steel than other hardening processes.

Flame Hardening.—Flame hardening, like induction hardening, involves no change in the chemical composition of the steel surface. In flame hardening, a high-temperature flame impinges directly on the work for a short time, heating the surface but not the interior of the piece. The depth of hardening is usually $\frac{1}{32}$

in. or greater. Bulky pieces are often hardened by this method. For instance, large gears 80 in. in diameter and weighing 2,500 lb. have been flame hardened to a depth of $\frac{3}{16}$ in. in production at a cost of about $15 each for the surface-hardening treatment. Small gears ($\frac{3}{4}$ in. face, 43 teeth) have been hardened at the rate of 150 per hour for eight cents apiece.

Choice of Methods.—The choice of a surface-hardening method depends on the design of the part, composition of the steel, type and depth of case needed, permissible distortion, production volume, initial investment and operating cost. Usually a given steel and treatment are compared with another steel-treatment combination.

The selection of case depth is also important because a deeper case usually costs appreciably more and may even be undesirable, especially on thin pieces, which become more brittle as the case depth is increased. (T. Ly.)

SURFACE TENSION. The title under which many surface phenomena—including Capillarity—are usually considered.

When the surface of water (or other liquid) in a tank is carefully examined it is found not to be perfectly level. The statement that water finds its own level is only approximate. The surface in fact becomes considerably curved near its edges where the liquid comes in contact with the wall of the tank.

If a vertical tube with a very narrow bore is placed with one end in the water, the liquid rises some distance above the level of the outer surface. The rise is greater the smaller the diameter of the bore. The rise of oil through a wick is a phenomenon of the same kind.

If a small quantity of mercury is poured on a horizontal plate it forms a drop. If the quantity is only a few cubic millimetres the drop is nearly spherical—a much larger quantity spreads out into a cake-shaped mass with a nearly flat top and with rounded edges.

A drop of oil placed on a clean water surface spreads almost instantaneously so as to form a very thin film. The thinness of the film can be judged from the colours that flash out or from the size of the area covered by even a small drop.

The phenomena of soap bubbles and the formation of froth in solutions of soap are also familiar ones. In these cases, also, thin films are formed.

The propagation of ripples of very short wave-length follows a different law from the propagation of deep sea waves.

When camphor is scraped so that the fragments fall upon a clean surface of water, they rush about on the surface with very rapid and rapidly changing motion. A minute quantity of oil placed on the surface brings them almost instantaneously to rest.

These and many allied phenomena, can all be studied under one heading. They arise from the existence of surfaces separating one medium from another.

The special forces which come into play are thence known as Surface forces. The rise in tubes of narrow bore—which are known as capillary tubes because the bore is as "fine as a hair" —is due to these forces. From the special way in which the effects arise in this case the action is called *capillary action*. This name, though often applied in other cases, is hardly applicable except to the case of narrow tubes; while the term *surface action* is applicable in all. The forces which are concerned in these phenomena are those which act between neighbouring parts of substances. These also produce the effects of cohesion.

Newton in the third edition of his *Opticks* refers to them in the following passage:—"The parts of all homogeneal hard Bodies, which fully touch one another, stick together very strongly . . . I . . . infer from their Cohesion that their Particles attract one another by some force which in immediate Contact is exceeding strong, at small distances performs the chymical Operations above mention'd, and reaches not far from the particles with any sensible Effect. . . . There are therefore Agents in Nature able to make the Particles of Bodies stick together by very strong Attractions. And it is the Business of experimental Philosophy to find them out."

These forces must be distinguished from those of gravity which also act between the particles of matter because these latter can act over very great distances. (The earth is controlled in its motion round the sun by gravitation.) Cohesion acts to any measurable extent only over minute distances. Sticks of chalk for drawing are made by highly compressing finely ground chalk and other materials. If a stick is broken and the two parts are brought into their original position as nearly as possible by hand they do not stick together because the neighbouring particles are still so far apart as to exert no sensible attraction. High pressure is needed for them to begin sensibly to attract each other. Before considering in detail how these attractions arise we give a historical summary of the development of the subject.

Historical.—(The following historical summary is taken from James Clerk Maxwell's classical article in the ninth edition of this Encyclopaedia, as modified by the 3rd Lord Rayleigh in the tenth edition.) According to J. C. Poggendorff (*Pogg. Ann.* ci. p. 551), Leonardo da Vinci must be considered as the discoverer of capillary phenomena, but the first accurate observations of the capillary action of tubes and glass plates were made by Francis Hawksbee (*Physico-Mechanical Experiments*, London, 1709, pp. 139–169; and *Phil. Trans.* 1711 and 1712), who ascribed the action to an attraction between the glass and the liquid. He observed that the effect was the same in thick tubes as in thin, and concluded that only those particles of the glass which are very near the surface have any influence on the phenomenon. Dr. James Jurin (*Phil. Trans.*, 1718, p. 739, and 1719, p. 1083) showed that the height at which the liquid is suspended depends on the section of the tube at the position of the meniscus, and is independent of the form of the lower part. Sir Isaac Newton devoted the 31st query in the last edition of his *Opticks* to molecular forces, and instanced several examples of the cohesion of liquids, such as the suspension of mercury in a barometer tube at more than double the height at which it usually stands. This arises from its adhesion to the tube, and the upper part of the mercury sustains a considerable tension, or negative pressure, without the separation of its parts. He considered the capillary phenomena to be of the same kind, but his explanation is not sufficiently explicit with respect to the nature and the limits of the action of the attractive force.

It is to be observed that, while these early speculators ascribe the phenomena to attraction, they do not distinctly assert that this attraction is sensible only at insensible distances, and that for all distances which we can directly measure the force is altogether insensible. The idea of such forces, however, had been distinctly formed by Newton, who gave the first example of the calculation of their effect in his theorem on the alteration of the path of a light-corpuscle when it enters or leaves a dense body.

Alexis Claude Clairault (*Théorie de la figure de la terre*, Paris, 1808, pp. 105, 128) appears to have been the first to show the necessity of taking account of the attraction between the parts of the fluid itself in order to explain the phenomena. He did not, however, recognize the fact that the distance at which the attraction is sensible is not only small but altogether insensible. J. A. von Segner (*Comment. Soc. Reg. Götting.* i. [1751] p. 301) introduced the very important idea of the surface-tension of liquids, which he ascribed to attractive forces, the sphere of whose action is so small "ut nullo adhuc sensu percipi potuerit."

In 1756 J. G. Leidenfrost (*De aquae communis nonnullis qualitatibus tractatus*, Duisburg) showed that a soap-bubble tends to contract, so that if the tube with which it was blown is left open the bubble will diminish in size and will expel through the tube the air which it contains.

In 1787 Gaspard Monge (*Mémoires de l'Acad. des Sciences*, 1787, p. 506) asserted that "by supposing the adherence of the particles of a fluid to have a sensible effect only at the surface itself and in the direction of the surface it would be easy to determine the curvature of the surfaces of fluids in the neighbourhood of the solid boundaries which contain them; that these surfaces would be *lintéariae* of which the tension, constant in all directions, would be everywhere equal to the adherence of two particles, and the phenomena of capillary tubes would then present nothing which could not be determined by analysis." He applied this principle of surface tension to the explanation of the apparent

attractions and repulsions between bodies floating on a liquid.

In 1802 John Leslie (*Phil. Mag.*, 1802, vol. xiv. p. 193) gave the first correct explanation of the rise of a liquid in a tube by considering the effect of the attraction of the solid on the very thin stratum of the liquid in contact with it. He did not, like the earlier speculators, suppose this attraction to act in an upward direction so as to support the fluid directly. He showed that the attraction is everywhere normal to the surface of the solid. The direct effect of the attraction is to increase the pressure of the stratum of the fluid in contact with the solid, so as to make it greater than the pressure within the fluid.

In 1804 Thomas Young (Essay on the "Cohesion of Fluids," *Phil. Trans.*, 1805, p. 65) founded the theory of capillary phenomena on the principle of surface tension. He also observed the constancy of the angle of contact of a liquid surface with a solid, and showed how from these two principles to deduce the phenomena of capillary action. His essay contains the solution of a great number of cases, including most of those afterwards solved by Laplace, but his methods of demonstration, though always correct, and often extremely elegant, are sometimes rendered obscure by his scrupulous avoidance of mathematical symbols. Having applied the secondary principle of surface tension to the various particular cases of capillary action, Young proceeded to deduce this surface tension from ulterior principles. He supposed the particles to act on one another with two different kinds of forces, one of which, the attractive forces of cohesion, extends to particles at a greater distance than those to which the repulsive force is confined. He further supposed that the attractive force is constant throughout the minute distance to which it extends, but that the repulsive force increases rapidly as the distance diminishes. He thus showed that at a curved part of the surface, a superficial particle would be urged towards the centre of curvature of the surface, and he gave reasons for concluding that this force is proportional to the sum of the curvatures of the surface in two normal planes at right angles to each other.

The subject was next taken up by Pierre Simon Laplace (*Mécanique céleste*, supplement to the tenth book, pub. in 1806). His results are in many respects identical with those of Young, but his methods of arriving at them are very different, being conducted entirely by mathematical calculations. For those who wish to study the molecular constitution of bodies it is necessary to study the effect of forces which are sensible only at insensible distances; and Laplace has furnished us with an example of the method of this study which has never been surpassed. He found for the pressure at a point in the interior of the fluid an expression of the form

$$p = K + \tfrac{1}{2}H(1/R + 1/R'),$$

where K is a constant pressure, probably very large, which, however, does not influence capillary phenomena, and therefore cannot be determined from observation of such phenomena; H is another constant on which all capillary phenomena depend; and R and R′ are the radii of curvature of any two normal sections of the surface at right angles to each other.

The next great step in the treatment of the subject was made by K. F. Gauss (*Principia generalia Theoriae Figurae Fluidorum in statu Aequilibrii*, Göttingen, 1830, or *Werke*, v. 29, Göttingen, 1867). The principle which he adopted is that of virtual velocities, a principle which under his hands was gradually transforming itself into what is now known as the principle of the conservation of energy. Instead of calculating the direction and magnitude of the resultant force on each particle arising from the action of neighbouring particles, he formed a single expression which is the aggregate of all the potentials arising from the mutual action between pairs of particles. This expression has been called the force-function. With its sign reversed it is now called the potential energy of the system. It consists of three parts, the first depending on the action of gravity, the second on the mutual action between the particles of the fluid, and the third on the action between the particles of the fluid and the particles of a solid or fluid in contact with it.

The condition of equilibrium is that this expression (which we may for the sake of distinctness call the potential energy) shall be a minimum. This condition when worked out gives not only the equation of the free surface in the form already established by Laplace, but the conditions of the angle of contact of this surface, with the surface of a solid.

In 1831 Siméon Denis Poisson published his *Nouvelle Théorie de l'action capillaire*. He maintained that there is a rapid variation of density near the surface of a liquid, and he gave very strong reasons, which have been only strengthened by subsequent discoveries, for believing that this is the case.

The result, however, of Poisson's investigation is practically equivalent to that already obtained by Laplace. In both theories the equation of the liquid surface is the same, involving a constant H, which can be determined only by experiment. The only difference is in the manner in which this quantity H depends on the law of the molecular forces and the law of density near the surface of the fluid, and as these laws are unknown to us we cannot obtain any test to discriminate between the two theories.

We have now described the principal forms of the theory of capillary action during its earlier development. In more recent times the method of Gauss has been modified so as to take account of the variation of density near the surface, and its language has been translated in terms of the modern doctrine of the conservation of energy. *See* Enrico Betti, *Teoria della Capillarità: Nuovo Cimento* (1867); a memoir by M. Stahl, "Ueber einige Punckte in der Theorie der Capillarerscheinungen," *Pogg. Ann.* cxxxix. p. 239 (1870); and J. D. Van der Waals' *Over de Continuiteit van den Gasen Vloeistoftoestand*. A good account of the subject from a mathematical point of view will be found in James Challis's "Report on the Theory of Capillary Attraction," *Brit. Assn. Report*, iv. p. 235 (1834).

J. A. F. Plateau (*Statique expérimentale et théorique des liquides*, 1873), who made elaborate study of the phenomena of surface tension, adopted the following method of getting rid of the effects of gravity. He formed a mixture of alcohol and water of the same density as olive oil, and then introduced a quantity of oil into the mixture. It assumes the form of a sphere under the action of surface tension alone. He then, by means of rings of iron-wire, discs and other contrivances, altered the form of certain parts of the surface of the oil. The free portions of the surface then assume new forms depending on the equilibrium of surface tension. In this way he produced a great many of the forms of equilibrium of a liquid under the action of surface tension alone, and compared them with the results of mathematical investigation. The debt which science owes to Plateau is not diminished by the fact that, while investigating these beautiful phenomena, he never himself saw them, having lost his sight in about 1840.

G. L. van der Mensbrugghe (*Mém. de l'Acad. Roy. de Belgique*, xxxvii., 1873) devised a great number of beautiful illustrations of the phenomena of surface tension, and showed their connection with the experiments of Charles Tomlinson on the figures formed by oils dropped on the clean surface of water.

Athanase Dupré in his 5th, 6th and 7th Memoirs on the Mechanical Theory of Heat (*Ann. de Chimie et de Physique*, 1866–68) applied the principles of thermodynamics to capillary phenomena, and the experiments of his son Paul were exceedingly ingenious and well devised, tracing the influence of surface tension in a great number of very different circumstances, and deducing from independent methods the numerical value of the surface tension. The experimental evidence which Dupré obtained bearing on the molecular structure of liquids must be very valuable, even if our present opinions on this subject should turn out to require modification.

GENERAL THEORY OF CAPILLARY ACTION

It is found by experiment that the forces between molecules to which cohesion is due only act perceptibly across very short distances. If we regard the forces between two particles as acting according to a law depending only upon their positions it must vary inversely as the distance according to a higher power than

that of the inverse square which is obeyed by gravitation. The experiments of Quincke and others show that the extreme range through which sensible effect is produced by them is certainly much less than a thousandth of a centimetre and it is probably less than one millionth.

In order to illustrate the important bearing of this limitation in range consider a molecule, A, well within a substance. A sphere

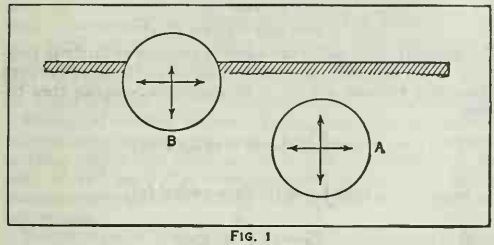

FIG. 1

of a thousandth of a centimetre radius may be drawn round it and the molecules outside this sphere will have no sensible influence on A. Those within the sphere attract A but in the case of a homogeneous isotropic body their pulls will be uniformly distributed and the resultant *force* on A will be zero. There will, however, be a pressure throughout the sphere due to the attraction: each spherical layer, being attracted, will compress the particles lying inside it. But if we consider a particle B very near the surface—nearer in fact than the range of action—the state of things will be found to be different. There will be more particles pulling B downwards than upwards so that all such particles as B will experience a resultant-*force* downwards. There will also be a *pressure* at B but its value is less the nearer B is to the surface. There is, therefore, a thin, indefinitely bounded, layer near the surface which is in a different condition from the main body of the substances. Many of the properties will be different in this surface layer from elsewhere. For example, corresponding to the different pressure, the density will be different. Since work is done in producing compression the potential energy will differ in the two regions. In the main body it can be written

$$\int \chi_0 \rho_0 dV = \chi_0 \rho_0 V_0$$

where V = volume, ρ density and χ the potential energy per unit mass; in the film, owing to its minute thickness, e, which we divide up into still thinner layers, de, and surface S we write

$$\text{Total mass} = V\rho_0 - S\int_0^e (\rho_0 - \rho)\, de$$

while the total potential energy (in terms of χ its value per unit mass) is

$$\int \chi \rho dV$$

or

$$V\chi_0\rho_0 - S\int_0^e (\chi_0\rho_0 - \chi\rho) de.$$

Multiplying the total mass by χ_0 and subtracting from the last expression

$$E - M\chi_0 = S\int_0^e (\chi - \chi_0)\rho de.$$

The right hand side is therefore an expression for that part of the energy which depends upon the existence of a surface S. The integral which multiplies it is the constant (or rather, factor) known as the *surface tension*. This integral is a measure of the work done in increasing the area of the surface. It must be carefully distinguished from the corresponding increase in the total energy because heat is drawn in simultaneously if the change takes place at constant temperature. It is in strictness a measure of the change in the "free-energy." (*See* THERMODYNAMICS: *Thermodynamics and Physical Chemistry.*)

By the principles of energy the potential energy (at constant temperature) tends to a minimum; in other words, any change that takes place spontaneously involves a diminution of this energy. Hence, whenever the surface tension is positive there will be a tendency for the surface to decrease, and the diminution will in fact take place unless it is resisted by other forces. This diminution takes place not by a contraction of the liquid but by a passage of the surface molecules into the body of the liquid. The properties of the body are not changed thereby. In this respect the phenomenon is quite different from the case of a stretched india-rubber film. In the case of the liquid the surface tension remains constant during the contraction of the surface area; in the case of the stretched india-rubber it diminishes along with the contraction.

We may express it otherwise by saying that if an imaginary straight line be drawn anywhere in the surface, when *equilibrium exists* there must be a force acting across the line in such a direction as to prevent further contraction of area. It is easy to show that this force per unit length of line is numerically the same as the surface-tension as defined above.

Dupré has described an arrangement by which the surface-tension of a liquid film may be illustrated. A piece of sheet metal is cut out in the form AA' (fig. 2). A very fine slip of metal is laid on it in the position BB' and the whole is dipped into a solution of soap. When it is taken out the rectangle $AA'CC'$ is filled by a liquid film. This film tends to contract on itself and the loose strip of metal will, if let go, be drawn towards AA'. If S is the area *of one face of the film* the potential energy is σS. If $AA' = b$ and $AC = a$ it is equal to σab. Hence if F is the force by which the slip is pulled towards AA', $F = \frac{d}{db}(\sigma ab) = \sigma a$; so that the force per unit length for one face is σ. Hence, σ is either the force per unit length or the potential energy per unit area.

It must be added that we have only considered one of the two faces and the force due to it. There is an equal force on the strip due to the second surface so that the total force is twice as great as the value taken. But the total area is twice as great also so that the conclusion remains unchanged.

There are other ways of illustrating the existence of the tension. Form a film as before but in a fixed frame. Tie a short length of spider line or fine unspun silk so as to form a flexible ring. If it is placed carefully on the film it usually takes an irregular shape. If the film inside the ring is destroyed by piercing it with a hot wire the spider line opens out into a circular form, this being the form which makes the surrounding surface least for a given length of line. Again, a small drop of mercury or a falling rain drop is practically spherical—the sphere being the form which has the smallest area for a given volume. A large drop fails to be spherical because gravitational forces are then strong enough to compete successfully with surface forces. Sometimes a difficulty is felt in connection with the assertion that the surface-tension is constant. Take a film such as we considered and place it vertically. The upward force on $AA' = 2\sigma a$ for the two faces, the downward force at the level CC' is also $2\sigma a$. The remaining force on the portion of the film between these lines is its weight. Hence the resultant force on the mass of the film is its weight and its acceleration should therefore be that of a freely falling body. Yet whatever may be found true for a pure substance, it cannot be true in general that the tension is the same at all parts of a large area. In the case of a soap film some adjustment must automatically take place (either by alteration of concentration or otherwise) which makes the upper tension a little greater than the lower. It is probably the power of such an adjustment being made in the case of a soap solution which is the leading requisite permitting a *durable* film to be made. Otherwise the film would literally fall to pieces.

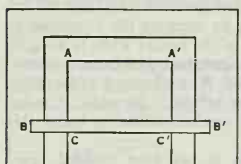

FIG. 2

Theory of Cohesion.—The mode in which cohesion is ex-

plained by assuming the existence of forces between elements (*i.e.*, infinitesimal volumes) of matter can be illustrated by supposing the substance of a body to be distributed continuously instead of partitioned into molecules. Such was the mode in which Laplace, more than a century ago, regarded it; and indeed it is the assumption that has always been made until recent times regarding the distribution of the substance of a body.

Let the force between two elementary volumes be supposed proportional to the product of the volumes and inversely as the nth power of their distances apart. The force required is that across unit area drawn anywhere well inside the body arising from the volumes on each side of it. The calculation is made in successive stages.

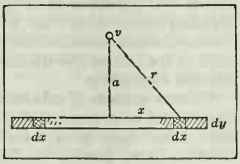

FIG. 3

(i.) Take a lamina of thickness dy. The force on an elementary volume v due to a zone of radius x and width dx is $v \cdot \frac{2\pi x\,dx}{r^n} \cdot \frac{a}{r}\,dy$ since the tangential components will cancel each other. Hence the whole lamina attracts the element with a force

$$2\pi va \int_a^\infty \frac{x\,dx}{r^{n+1}} \cdot dy = 2\pi va \int_a^\infty \frac{dr}{r^n}\,dy.$$

This becomes $\frac{2\pi va}{(n-1)a^{n-1}}\,dy$ or $\frac{2\pi v}{(n-1)a^{n-2}}\,dy$ since we assume the forces to vanish at infinity.

(ii.) Let v be an element in a parallel lamina of thickness da. Then the total force per unit area on such a lamina II. is obtained by putting $v = da$. Hence we find the force on a semi-infinite solid above lamina II. due to lamina I. by integrating from o to ∞ that is

$$\text{Force on semi-solid (per unit area)} = \frac{2\pi dy}{n-1} \int_0^\infty \frac{da}{a^{n-2}}$$

$$= \frac{2\pi}{(n-1)(n-3)} \left| \frac{1}{a^{n-3}} \right|_0^\infty$$

(iii.) The force (per unit area) on such a semi-infinite body due to a semi-infinite body in contact with it is obtained by integrating with respect to y from $y = 0$ to $y = \infty$. This force is the cohesion per unit area and is given by

$$K_0 = \frac{2\pi}{(n-1)(n-3)(n-4)} \left| \frac{1}{a^{n-4}} \right|_0^\infty$$

The unit of force used is that between two unit volumes separated by unit distance.

Lord Rayleigh remarks: "The pressure will therefore be infinite whatever n may be. If $n-4$ be negative the attraction of infinitely distant parts contributes to the result; while if $n-4$ be positive the parts in immediate contiguity act with infinite power. For the transition case, discussed by W. Sutherland (*Phil. Mag.* xxiv. p. 113, 1887) of $n=4$, K is also infinite." He adds "It seems therefore that nothing satisfactory can be arrived at under this head."

In more recent times, however, it has been realized (particularly by the Dutch school of physicists) that to treat the body as a *continuum* is bound to give erroneous results. Every substance is known to be built up of molecules. If we assume the existence of attractions depending on the distance between the centres of the molecules it is at the same time necessary to recognize that the two halves of the body can never approach to absolute contact. The lower limit in the last integration should be the least distance of separation between the lines of centres of contiguous layers. This will be a magnitude comparable with the molecular diameter, say s. The value we seek then becomes

$$K_0 = \frac{2\pi}{(n-1)(n-3)(n-4)} \cdot \frac{1}{s^{n-4}}.$$

There is now no objection on the above grounds to the power law provided that $n > 4$.

There can be no doubt that if the amount of matter compressed into unit volume (*i.e.*, the density ρ) be increased the value of the intrinsic pressure would be increased. Moreover, a factor Γ (akin to the gravitation constant) is also needed if K is to be expressed in ordinary dynamical units. Hence finally

$$K = \Gamma \cdot \frac{2\pi\rho^2}{(n-1)(n-3)(n-4)} \cdot \frac{1}{s^{n-4}}.$$

The quantity, K, is called the Laplace pressure or intrinsic pressure. More generally we could assume that the force between elementary volumes is $f(r)$. The successive integrals then become

i. $$2\pi a \int_a^\infty f(r)\,dr\,dy = 2\pi a\phi(a)\,dy;$$

ii. $$2\pi dy \int_y^\infty a\phi(a)\,da = 2\pi dy\,\psi(y);$$

iii. $$K_0 = 2\pi \int_s^\infty \psi(y)\,dy$$

where ϕa, ψy are written as the values of successive integrals. Finally K is obtained in ordinary units by multiplying by $\Gamma\rho^2$ For example if $f(r) = \epsilon^{-kr}$ where k is a constant we have

$$\psi(s) = \frac{ks+1}{k^3}\,\epsilon^{-ks}.$$

The difficulty in testing these formulae arises from the occurrence of three variables (k, s, Γ). The only one of these about which we know the value independently is s which for liquids must be of the same order as the molecular diameter. Caution is necessary in considering forces which vary so fast with the distance as cohesive forces undoubtedly do. A small error in the assumed value for s would lead to very considerable error in k and Γ. The intrinsic pressure *at the breaking point* of a solid in tension should be the breaking stress itself. The latter as actually measured is, however, only a lower limit of K since flaws in the material and irregularities in the application of the tension will lead to fracture occurring at a value lower than the ideal stress. The effect of cohesion on the characteristic equation of a gas was allowed for by van der Waals who, following Laplace, took the intrinsic pressure as varying with the density square alone. The equation becomes

$$(p + a\rho^2)(v - b) = RT$$

where at the same time b is introduced to represent the fact that the volume of the gas cannot be reduced to zero. Here $K = a\rho^2$ which for water at ordinary densities is between 10–20 Atmos. The fact that the equation turns out to be approximate only makes caution necessary. Moreover a is found to vary nearly inversely as the absolute temperature. We are obliged to assume, therefore, either that Γ is a function of the temperature or, what is more likely, that s is such a function. The latter assumption is indeed a very plausible one, for the least average distance of approach of the molecules must be affected by the motion of agitation amongst them and this increases as the square root of the absolute temperature.

Besides these considerations it must be pointed out that the modification worked out by the Dutch school only partly allows for the effects arising from the molecular character of matter. Knowing the forces between two molecules at a given distance apart, the actual value of the intrinsic pressure could only be correctly obtained by summing up the components (normal to the interface at which the pressure is being calculated) of all the forces between every pair of molecules each being calculated for the actual positions in which the molecules instantaneously are. It is true, that with forces that vary so fast with distance it is only the molecules which are fairly near to a point whose individual contributions are important: the contributions of the remainder may be estimated by an approximate method such as that followed by Laplace. Something has been done in this direction (Lennard-Jones, *Faraday Society*, "Discussion on co-

hesion," 1927) but the fact remains that though the law of force is probably greater than the inverse fifth it may vary up to the inverse seventh so far as present knowledge goes. If we take the higher of these two estimates the force between molecules which are neighbours and those that are next door to neighbours will be as 2^7 to 1, *i.e.*, in the ratio 128 to 1 or that between any layer and the next and next but one contiguous layer as 2^6 to 1, *i.e.*, in the ratio of 64 to 1. Hence all but a small percentage of the intrinsic pressure is due to the molecules in a small volume surrounding the point. This conclusion is important since it signifies that in any material (gas, liquid, solid) the intrinsic pressure will be uniform at all points except for a thin layer of usually negligible volume near its boundary.

Theory of Surface Forces.—This surface layer has theoretically no inner boundary but it may be taken, for most purposes, as being only a few molecules thick (mol. diameter is of the order of 10^{-8} cm.). The most prominent peculiarity is that it possesses more potential energy than the rest of the body per unit volume.

Now increase of free energy at constant temperature is equal to the external work done on a system. If we write $dW = \sigma dA$ σ is called the surface tension. To determine its value theoretically we estimate dW for the formation of a surface of unit area. Now if a body is split by a plane section and the two halves separated, a fresh surface is formed. The attraction per unit area between the halves at any distance x is

$$2\pi\int_x^\infty \psi(y)dy = K(x) \text{ say.}$$

The total work of separation is $\int_s^\infty K(x)\,dx$ and in the process a fresh area of 2 units is formed. Hence expressing the work done in ordinary units

$$2\sigma = 2\pi\Gamma\rho^2\int_s^\infty K(x)dx$$

(In previous editions many theorems were given [some of which date from Laplace] which depend, however, upon the lower limit being zero. It is sufficient to say that these theorems are not applicable to the formulae given here.)

If a power law is taken as the law of force between molecules it follows that

$$\sigma = \frac{\pi\rho^2\Gamma}{(n-1)(n-3)(n-4)(n-5)s^{n-5}}.$$

This law may be combined with that for K with the result that

$$\frac{K}{\sigma} = \frac{2(n-5)}{s}.$$

For water at ordinary temperature, approximately

$$K = 10{,}000 \text{ Atm.} = 10^{10} \text{ dynes/sq.cm.}$$
$$\sigma = 75 \text{ dynes/cm.}$$
$$s = 4\times10^{-8} \text{ cm.}$$

Whence, $$n-5 = \frac{10^{10}\times4\times10^{-8}}{2\times75} = \frac{8}{3}$$

and $$n = 7{\cdot}67.$$

It must not be forgotten, however, that K and s are obtained by very approximate methods only.

Interfacial Tensions.—When two liquids are in contact there is in general a surface-tension at the interface which is called interfacial tension. Denoting this by σ_{12} and the tensions of the liquids as σ_1 and σ_2 respectively, and carrying out a separation of the two liquids the value of σ_{12} can be determined. In the above process the interface between 1 and 2 disappears and two fresh surfaces appear at which the tensions are σ_1 and σ_2. Hence

$$\sigma_2+\sigma_1-\sigma_{12} = 2\pi\rho_1\rho_2\int_{\frac{s_1+s_2}{2}}^\infty K(x)dx$$

where the lower limit is the sum of the radii of the two kinds of molecules. Hence

$$\sigma_{12} = \pi\rho_2^2F(s_2)+\pi\rho_1^2F(s_1)-2\pi\rho_1\rho_2F\left(\frac{s_1+s_2}{2}\right).$$

Young took the functions F as being identical being all the same function of zero instead of the molecular diameters;

whence $$\sigma_{12} = \pi(\rho_2-\rho_1)^2F(0)$$

or $$\sqrt{\sigma_{12}} = \text{const.}\times(\rho_2-\rho_1).$$

Hence for three liquids taken pair by pair

$$\sqrt{\sigma_{12}}+\sqrt{\sigma_{23}}+\sqrt{\sigma_{31}} = 0.$$

These simplified relations are known not to be true. On the other hand if the power law is valid and is the same law for different substances the equations given here lead to

$$\sigma_{12} = \left(\frac{\rho_2^2}{\sigma_2^{n-5}}+\frac{\rho_1^2}{\sigma_1^{n-5}}-\frac{2\rho_1\rho_2}{\left(\frac{s_1+s_2}{2}\right)^{n-5}}\right)\frac{\pi}{(n-1)(n-3)(n-4)(n-5)}$$

and the square root law should not be expected to be true excepting in special cases in which the molecular diameters of the three substances were the same.

All surface-tensions with which we have to deal are in reality interfacial tensions since a liquid is always in contact with its own vapour or the gas in which it is immersed. The effect due to the gas is known, however, to be very small.

The normal pressure to be expected from the existence of a superficial tension is best obtained by considering in the first place a cylinder.

Consider an element of surface, $ds\times$unity. The tensions acting at its extreme edges are inclined to one another and have a resultant inwards. Their resultant is a normal force $2\sigma\sin\frac{d\theta}{2}$ or in the limit $\sigma d\theta$. But $\frac{ds}{d\theta} = R$ (the radius of curvature); hence the normal force is $\sigma\frac{ds}{R}$. Since this acts over an area equal to ds, the normal pressure is σ/R.

If we take a body of any shape and select a square-bounded element of the surface, the tensions in the plane of the diagram are equivalent to a normal force $\sigma ds_1\times\frac{ds_2}{R_1}$ and those acting on the other two edges to $\sigma ds_2\times\frac{ds_1}{R_2}$. Hence per unit area

$$p = \sigma\left(\frac{1}{R_1}+\frac{1}{R_2}\right).$$

Here R_1 and R_2 are the radii of curvature in two planes at right angles. Owing to Gauss's theorem of integral curvature the sum of two such curvatures at a point is a constant. The above theorem is therefore true whether the two rectangular planes considered are principal planes or otherwise. In the case of a sphere

$$p = \frac{2\sigma}{R}.$$

Effect of Temperature.—The variation of surface tension with temperature was not taken into account in Laplace's theory. The forces between molecules were taken, like gravitational forces, to be independent of temperature. The rise in a capillary tube was supposed to vary merely because the density varied. Experiment has shown, however, that the tension itself in all cases diminishes with rise in temperature. That it must ultimately diminish to zero can be inferred from the fact that according to the usual conceptions as to the critical state a liquid and its vapour will at that point become identical with one another; the tension at the interface must then be zero. Eotvös introduced the conception of molecular surface tension. By means of somewhat doubtful reasoning he concluded that $\sigma(Mv)^{\frac{2}{3}}$ (where Mv is the molecular volume), plotted against temperature should give

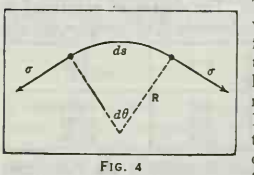

FIG. 4

the same kind of curve for different substances, and he found in fact that it was representable by $K(T_c-T)$ where T_c is the critical temperature and K a constant. According to Ramsay and Shields K should be the same constant for all non-associated substances. In reality K varies betyeen 1·5 and 2·6 and it is necessary also to change T_c-T to $T_c-T-\delta$ where δ is a small constant, so that the law is only a rough one. According to this equation the curve would be a straight line cutting the temperature axis a few degrees below the critical point.

In connection with this, it is important to remember that σ is only the free energy per unit area and not the total energy per unit area (u). Lord Kelvin was the first to prove that the variation of σ with temperature, involves that u must be greater than σ; or in other words, when an expansion of the surface takes place heat must be added to keep the temperature constant. The connection between these quantities he proved thermodynamically to be $u = \sigma - T\frac{d\sigma}{dT}$ (*vide* THERMODYNAMICS applied to chemistry). Now, at the critical point, u (which is only the *extra* energy due to the existence of unit surface and not the total energy of the whole body) must also vanish. But if both u and σ are then zero so also must $T\frac{d\sigma}{dT}$ be zero.

Hence, if our conceptions of the critical state are correct the curve of σ plotted against T instead of being a straight line must become horizontal at the critical point. In 1894, van der Waals showed that a formula of the type $\sigma = A(T_c-T)^n$ was to be expected and gave the average value of $n = 1·27$ as deducible from the experimental values. In 1916 A. Ferguson (*Phil. Mag.*, Jan. 1916), examining the data for 14 different organic substances showed that the best values of n ranged from 1·187 to 1·248. The advantageous character of this power equation is that it makes σ, u, and $\frac{d\sigma}{dT}$ all equal to zero at the critical point and it thus satisfies all that is required of it theoretically. Liquids, however, which are believed to be associated do not follow the above simple law.

The surface energy, u, also falls to zero at the critical point, but according to a different law. For taking the equation

$$u = \sigma - T\frac{d\sigma}{dT}$$

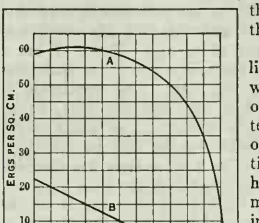
it follows that $u = A(T_c-T)^{n-1}(T_c+[n-1]T)$. The curves for σ and u are shown in fig. 5 for the case of benzene. The curve shows how nearly a straight line law satisfies the values of σ until the critical point is closely approached. An interesting relation has been given by Prof. E. T. Whittaker between u and the latent heat (internal) of *evaporation*. The internal latent heat (L_i) is obtained by subtracting the external work done from the ordinary latent heat. The relation in question is that $\frac{T_c}{T}\cdot\frac{u}{L_i}$ is nearly a constant, and that (in C.G.S. units) this constant is about unity for ethyl oxide, methyl formate, benzene and chlorobenzene and about 2 for carbon tetrachloride. The degree of constancy is indicated in the following table for benzene (Crit. temp. = 561.5A)

T°A	$\frac{T_c u}{TL_i}$	T°A	$\frac{T_c u}{TL_i}$
353	1·106	493	1·089
403	1·100	503	1·106
453	1·067	513	1·129

The relation is important since it indicates the close connection there is between the surface energy and the volume energy of the substances.

General Properties of Surface Tension.—The notion of surface tension, though it is only a derived one, enables us to deal with all the phenomena which were enumerated at the head of this article without making explicit reference to the more fundamental notion of molecular attractions upon which they in reality depend. It is appropriate to summarize here the leading characteristics of this property.

The tension of a liquid across any straight line drawn on the surface is normal to that line and is the same for all directions of the line and is measured by the force across an element of the line divided by the length of that element.



BY COURTESY OF THE FARADAY SOCIETY

FIG. 5

For any given homogeneous liquid surface, as the surface which separates water from air or oil from water, the surface tension is the same at every point of the surface and in every direction. In the case of mixtures, however, when circumstances demand it (*e.g.*, when the surface is inclined and the effects of a gravitation field require consideration) the concentration at the surface may adjust itself from point to point of the surface in such a way as to produce a corresponding variation in the value of the surface tension sufficient to satisfy the conditions of equilibrium. This effect is very minute and in nearly every problem may be ignored.

When the surface is curved the effect of the surface tension is to make the pressure on the concave side greater than that on the convex side by the amount $\sigma(C_1+C_2)$ where C_1 and C_2 are the curvatures in mutually perpendicular normal planes.

The tension of the surface separating two liquids cannot be deduced by any reliable method from the tensions of the liquids when separately in contact with air. The experiments of C. G. M. Marangoni, van der Mensbrugghe, and Quincke have led to results which show that the common surface between two liquids has a tension always less than the difference of the tensions of the separate liquids. This is usually referred to as Marangoni's rule.

If three liquids meet along a line the interfaces at the common edge must be parallel to the sides of a triangle proportional to the three tensions σ_{12}, σ_{23}, σ_{31} otherwise equilibrium cannot obtain (Neumann's rule). This triangle cannot exist unless two of the interfacial tensions are greater than the third. Marangoni's experimental rule shows that the triangle is always imaginary. Hence three pure fluids (of which one may be a gas) accordingly cannot remain in contact. If a drop of oil stands in a lenticular form upon a surface of water, it is because the water-surface is already contaminated with a greasy film.

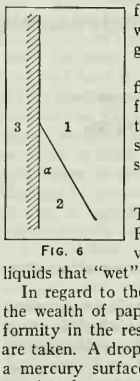


FIG. 6

When a solid body is in contact with two fluids the surface of the solid cannot alter its form but the angle at which the surface of contact of the two fluids meets the surface of the solid must depend on the values of the three surface tensions. For equilibrium

$$\sigma_{31}-\sigma_{32}=\sigma_{21}\cos\alpha.$$

The angle α is known as the angle of contact. For pure substances the angle is definite. It varies from zero (or very nearly so) for liquids that "wet" the solid to 130° or 140° for mercury on glass.

In regard to the experimental behaviour of water on mercury the wealth of papers is equalled by the remarkable lack of uniformity in the results obtained even when elaborate precautions are taken. A drop of water which fails to spread when placed on a mercury surface is often caused to spread by the action of pouring the mercury out of the dish—thus involving the creation of a new surface! Water shows a positive tendency to spread *in vacuo* on a drop *formed in vacuo!* (Burdon, *Faraday Society*, May, 1927).

Form of a Capillary Surface.—The form of the surface of a liquid acted on by gravity is easily determined if we assume that near the part considered the line of contact of the surface of the liquid with that of the solid bounding it is straight and horizontal.

This will be the case, for example, near a flat plate dipped into the liquid. Let A_2P_2 be the vertical plate supposed to be so wide that the edge effects do not count. We will consider the forces per unit depth (perpendicular to the paper) and will consider A_1A_2 as the standard level of the liquid far from the plate. The curvature of the surface at the point x, y, is

$$\frac{d\theta}{ds} = \sin\theta \frac{d\theta}{dy} = -\frac{d(\cos\theta)}{dy}$$

and consequently the pressure in the liquid at that point is less than the pressure outside it by $-\sigma \frac{d(\cos\theta)}{dy}$. But the pressure is less than that at a distant point where the surface is flat by $g\rho y$ or $g(\rho-\rho_0)y$ if allowance is made for the surrounding gas. Hence the differential equation for the surface is

$$-\frac{d(\cos\theta)}{dy} = \frac{g(\rho-\rho_0)}{\sigma} y$$

the integral of which is $1-\cos\theta = 2\sin^2\frac{\theta}{2} = \frac{g(\rho-\rho_0)}{\sigma} \cdot \frac{y^2}{2}$.

The shape of the surface is therefore the *elastica, i.e.*, the form taken by a uniform spring when equal and opposite forces are applied at its ends (*see* Thomson and Tait, *Natural Philosophy*, vol. i. p. 455). The equation might have been found by considering the elementary volume of a strip of liquid, dx, sustained above the normal level of the liquid by the surface forces at its outer and inner edges. The difference of the vertical component of these is $\sigma d(\sin\theta)$ and the weight of the strip is $g\rho y dx$ but since $\frac{d(\sin\theta)}{dx} = -\frac{d(\cos\theta)}{dy}$ the same result is obtained.

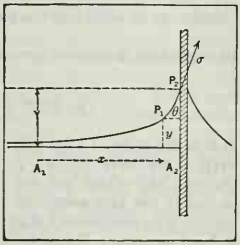

FIG. 7

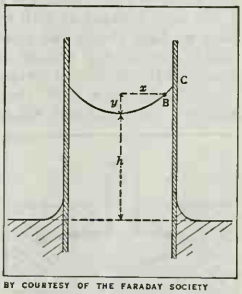
If the angle of contact is α the value of θ at the plate is $\frac{\pi}{2} - \alpha$; hence

$$1-\sin\alpha = \frac{g(\rho-\rho_0)}{\sigma} \cdot \frac{Y^2}{2}$$

which gives the greatest height through which the liquid is raised. A thin sheet of glass suspended from the arm of a balance and just dipping into a liquid provides a simple way of determining the surface tension. The increase in the apparent weight of the sheet when the liquid has been raised by capillarity is σ multiplied by twice the horizontal length of the sheet. A sensitive form of this apparatus is known as Worthington's multiplier in which the strip is rolled into a vertical cylindrical spiral.



BY COURTESY OF THE FARADAY SOCIETY
FIG. 8

Ascent up a Capillary Tube.—A capillary tube dipped in a liquid provides a simple method of determining surface tension. To connect the surface tension with the rise (or descent) of the liquid in the tube measured from the level part of the outside surface we equate the effective weight of the liquid raised to the total force due to the tension. The effective weight (with the symbols shown on diagram) is

$$g(\rho-\rho_0)\int_0^z 2\pi x(h+y)dx$$

for an inner cylinder of radius x where ρ is the density of the liquid and ρ_0 that of the surrounding gas or vapour. The vertical component of the surface force acting all round the edge of the liquid surface of this cylinder is $2\pi x\sigma\sin\theta$ or $2\pi x\sigma\cos\alpha$ where θ is the angle between the surface and the horizontal and α is the "contact-angle" which is measured with respect to the solid surface (in this case the vertical). These two expressions are to be equated to one another.

If we can neglect y altogether compared with h and integrate between the limits 0 and r we obtain $2\pi r\sigma\sin\theta = g(\rho-\rho_0)\pi r^2 h$ whence $\sigma\sin\theta = \frac{1}{2}g(\rho-\rho_0)rh$. To seek for a better approximation we first differentiate the two sides of the equation whence

$$\frac{d(x\sin\theta)}{dx} = \frac{g(\rho-\rho_0)}{\sigma} x(h+y) = \frac{x(h+y)}{\beta^2}.$$

We may consider this as the standard exact equation. The left side is

$$\frac{x\,d\sin\theta}{dx} + \sin\theta \quad \text{or} \quad x\left(\frac{\cos\theta\, d\theta}{dx} + \frac{\sin\theta}{x}\right).$$

But $\cos\theta\frac{d\theta}{dx} = \frac{d\theta}{ds}$ (where ds is an element of the curve AC) and is $\therefore$ the curvature in the plane of the diagram at B; and $\frac{\sin\theta}{x}$ is the curvature of the surface at B in a plane at right angles to the diagram. Hence, calling these curvatures $\frac{1}{R_1}$ and $\frac{1}{R_2}$ we have

$$\sigma\left(\frac{1}{R_1}+\frac{1}{R_2}\right) = g(\rho-\rho_0)(h+y);$$

both of the terms here are expressions for the difference of pressure between the two sides of the surface at the point B.

Narrow Tubes.—The equation shows that the sum of these curvatures increases with the height; but when h is big and y small, as it is for a very narrow tube, the sum is nearly constant. Going back to the differential form of the equation and taking the case where the liquid wets the tube, we may consider the curve as practically circular, of radius r; the corresponding value of $y = r - \sqrt{r^2-x^2}$ and

$$\frac{d(x\sin\theta)}{dx} = \frac{1}{\beta^2}(h+y)x = \frac{x}{\beta^2}(h+r-\sqrt{r^2-x^2}) \text{ nearly whence, by integration}$$

$$x\sin\theta = \frac{1}{\beta^2}\left[\frac{hx^2}{2} + \frac{rx^2}{2} + \frac{1}{3}\{(r^2-x^2)^{\frac{3}{2}} - r^3\}\right].$$

or since $\sin\theta = 1$ when $x = r$

$$1 = \frac{r}{2\beta^2}\left(h + \frac{r}{3}\right).$$

By putting the radius of the circle as $R = \frac{r}{\cos\alpha}$ when the angle of contact is α instead of zero this becomes

$$\cos\alpha = \frac{r}{2\beta^2}\left[h + \frac{r}{3\cos^3\alpha}\{1 - 3\sin^2\alpha - 2\sin^3\alpha\}\right].$$

By calculating $\tan\theta$ from $\sin\theta$ and bearing in mind that

$$\tan\theta = dy/dx,$$

we can by subsequent integration obtain a closer value of y in terms of x which can, in turn, be introduced into the differential equation and so on. By such successive approximations Lord Rayleigh has obtained the equation for the case $\alpha = 0$ in the form

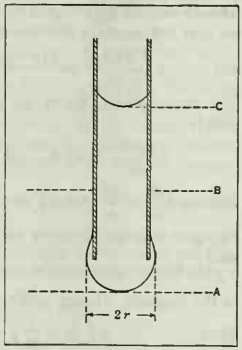
$$\sigma = \tfrac{1}{2}g(\rho-\rho_0)hr\left[1 + \frac{1}{3}\frac{r}{h} - 0{\cdot}1288\frac{r^2}{h^2} + 0{\cdot}1312\frac{r^3}{h^3}\right]$$

in which the coefficients are claimed to be correct to the approximation given. The equation can only be used in the case when r is small compared with h. It may be mentioned that a very near approach to the equation can be obtained by considering the surface as ellipsoidal with its minor axis vertical. This was first shown by Hagen and Desains. Various methods are employed for determining surface tension experimentally:

(*a*) From the rise in a capillary tube making use of the above equation.

(*b*) *Sentis's Method.*—A capillary tube is partly immersed in the liquid. It is then withdrawn vertically and a drop remains

clinging to the lower end; the position A of the vertex of the drop is noticed. The liquid in the vessel is then raised until it touches the vertex (when the column falls) and then raised further till the upper surface is at the same level C as at first. The liquid in the vessel is then at the level B. The vertical distance AB corresponds to h in the ordinary method but in the *correcting terms* h must be put negative. The width of the *drop* is in this case to be small compared with h.



BY COURTESY OF THE FARADAY SOCIETY
FIG. 9

(*c*) *Jaeger's Method.*—In this method an orifice (a "tip") is placed just under the surface of the liquid and the pressure of gas is increased until bubbles form. The *maximum* pressure of the gas (which is fairly sharply marked) is observed. The deduction of the applicable equation is a somewhat delicate matter because the problem is really a kinetic, not a static, one. The formula employed is

$$\sigma = \frac{p_{\max} r}{2}\left[1 - \frac{2}{3}\frac{r}{h}\right]$$

where $p_{\max}$ is the maximum difference of pressure between the level of the end of tube inside and outside, and r is the internal radius of the tube. The bubble is assumed to form within the internal circumference. In practice, however, it sometimes forms on the outside circumference. To obviate the uncertainty it is recommended to make the two circumferences as nearly equal as possible, but this is an experimental matter of great difficulty. The final accuracy depends chiefly on the measurement of the radius r. The subject of the formation of bubbles and drops requires much more study than it has received.

(*d*) *Drop Weight Method.*—This method is connected with the preceding one because the drops considered are those issuing from a narrow tube. It was employed by Tate (1864) who gave as the result of his observations:—Other things being the same, the weight of a drop of liquid is proportional to the diameter of the tube in which it is formed. Later, Quincke used it and gave the value $2\pi r\sigma$ as the weight of the suspended drop just before falling provided that the inflow of liquid is sufficiently slow. A portion of the drop is always left behind when the main part falls; but he considered that it might be neglected in the case of very small drops.

Rayleigh has discussed the question from the "dimensional" point of view. (*See* DIMENSIONAL ANALYSIS.) Assume that the mass M of the drop depends only upon the surface tension, σ, the value of acceleration due to gravity, g, the density of the liquid, ρ, and the inside radius, a, of the tube. Rayleigh shows that $\sigma a/g$ has the same dimensions as a *mass* and that $\sigma/g\rho a^2$ is a pure number. Since quantities that can be equated together must be quantities of the same kind, it follows that $M \propto (\sigma a/g)F(\sigma/g\rho a^2)$ where there is no restriction, imposed by this method of inquiry, upon the function F of the quantity in the second pair of brackets. Rayleigh finds by experiment that $gm/\sigma a$ is fairly constant for wide ranges in the diameter of the tube. For thin-walled tubes in the case of water the following values were obtained:

$\frac{\sigma}{g\rho a^2}$	$\frac{gM}{\sigma a}$	$\frac{\sigma}{g\rho a^2}$	$\frac{gM}{\sigma a}$
2·58	4·13	·277	3·78
1·16	3·97	·220	3·90
·708	3·80	·169	4·06
·441	3·73		

The mean value of the constant is thus about 3·8 instead of 2π which the imperfect theory gave. Further experiments by Harkins and Brown show that the constant approaches Quincke's value as the diameter becomes very small.

As a means for measuring surface tension this method is obviously not satisfactory; but for rough comparative values for liquids of like kind it is a very quick and easy method.

Wide Tubes.—When a is not small the approximations made above for narrow tubes are not suitable.

The question has been fully discussed by the late Lord Rayleigh to whose papers reference should be made (*v.* Rayleigh, *Proc. Roy. Soc.* A, 92, 184, 1915).

Bubbles and Drops.—These can be dealt with by similar methods. Air bubbles in a liquid can be formed of any size, from minute ones which are nearly spherical to large ones shaped like a flat cake. The excess pressure $p - p_0$, which is easily found by experiment, determines the total curvature at the lowest point N; being equal to $\frac{2}{R}$. If y is reckoned upwards as before, then

$$\frac{d(x\sin\theta)}{dx} = \left(\frac{2}{R} + \frac{y}{\beta^2}\right)x :$$

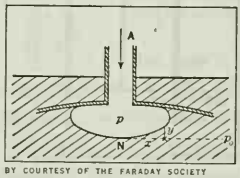
thus $\frac{2}{R}$ replaces h/β^2 in the previous problems. For very large bubbles, as for wide tubes, a good approximation can be obtained by neglecting the second curvature and also $\frac{2}{R}$, so that

$$(1 - \cos\theta) = \frac{y^2}{2\beta^2} = 2\sin^2\frac{\theta}{2}.$$

If H is the value of y for which the tangent to the curve becomes vertical we have $H = \sqrt{2}\cdot\beta$. This method has been used by Quincke and others but not always with bubbles large enough to justify the approximation that is made. The bubble is conveniently formed under a slightly concave surface so as to prevent it from escaping. Drops of mercury are easily formed above a concave surface. If y is measured *downwards* from the summit the same formulae hold as for bubbles.

Great attention has been paid to these methods owing to their use in determining surface-tension. The most thorough treatment from the practical point of view is given by Bashforth and Adams (*Capillary Action*, 1883). By means of infinite series calculated for each of the variables each term in the differential equation can be calculated to very high accuracy and tables are drawn up enabling the form to be determined for given weights of material and given surface tensions.

Thin Films.—In this section we consider thin films. The first group of cases consists of those in which the substance forms a thin sheet with gas on both sides, as for example, a soap bubble. Here we have always two surfaces to consider. When the thickness is considerably greater than the value of the range, ϵ of molecular forces the two surfaces are independent of one another; the surface-tension must then have the usual value for each. For very thin films this will not be so. If the thickness is less than the range, ϵ, the tension for each surface will be certainly less than the normal value. When the variation of density at different levels in the film is taken into account it is clear that the reduction in the surface-tension must begin when the thickness is twice ϵ.



BY COURTESY OF THE FARADAY SOCIETY
FIG. 10

A soap film is simply a small quantity of soapsuds spread out so as to present a large surface to the air. The soap solution may with great advantage be specially prepared. The addition of glycerine and resin enables more permanent films to be prepared. Bubbles may easily be blown 20 in. in diameter in the open air using a clay pipe or a small glass funnel. (The method needs no precise description.) Sir James Dewar has obtained bubbles that last almost indefinitely if evaporation be prevented by blowing them in a confined space saturated with water vapour.

The pressure inside a bubble is greater than that outside by

$2\sigma\left(\frac{1}{R}+\frac{1}{R}\right)$, *i.e.*, by $4\sigma/R$ where R is the radius of curvature.

The factor 2 arises because both surfaces give rise to normal components of forces. This result is easily obtained by considering the equilibrium of each *half* of the bubble. The force at the cut edge is $2\sigma \cdot 2\pi R$ and this is balanced by the excess pressure acting over the plane area πR^2. Hence the excess pressure is

$$\frac{2\sigma \cdot 2\pi R}{\pi R^2} = \frac{4\sigma}{R}.$$

If the end of the pipe or funnel is opened the bubble will contract because of the escape of high pressure air from inside. As it contracts the pressure rather paradoxically increases. It may be added that (neglecting gravity) the bubble is spherical because this *shape* makes the surface area (and therefore the potential energy) least for a given volume.

If bubbles are blown on the expanded ends of two funnels (the stems being stopped by the fingers) they can be made to coalesce by carefully bringing them into contact. (A slightly electrified rod brought not too near will assist the coalescence.) On drawing the funnels slowly apart a cylindrical bubble is obtained. The excess pressure is now $2\sigma/R$ where R is the radius of the opening of the funnel. Further separation causes the cylinder to contract in the middle; one of the two curvatures is now negative; the surface is an *anticlastic* one. With further extension of length the surface becomes unstable and the film collapses. It has been shown by Clerk Maxwell that a cylindrical film becomes unstable when its length is greater than its circumference.

Films on Liquids.—In the second group of cases a liquid or solid is on one side and a gas on the other. To this group belong all cases of the spreading of oil or other substance on water or other liquid or solid. This old familiar subject has recently acquired very great importance in its bearing upon molecular structures. The first to experiment in detail on such films was F. H. R. Lüdtge (*Pogg. Ann.* cxxxix., p. 620), who showed how a film of high surface tension is replaced by one of lower surface tension. Akin to these are experiments made on the erratic movements that are observed when fragments of camphor are sprinkled on a *clean* water surface. A trace of grease such as may be communicated to the surface by dipping a finger in the water may be sufficient practically to stop this motion. The thickness of oil which is required may be spoken of as the "camphor-point." The first to determine it was (the 3rd) Lord Rayleigh who in 1890 (*Roy. Soc. Proc.*) showed that the thickness of the film of olive oil, calculated as if continuous (*i.e.*, non-molecular) which corresponds to the camphor-point is about 2×10^{-6} mm.; *i.e.*, it is only a moderate multiple of the supposed diameter of a gaseous molecule and perhaps scarcely exceeds at all the diameter to be attributed to a molecule of oil; and he ultimately realized that this phenomenon was therefore entirely outside the scope of a theory of surface action such as Laplace's in which matter is regarded as continuous and that an explanation required a direct consideration of molecules.

In 1891 Miss Pockels (*Nature*, xliii., 437 [1891]) showed by means of a movable slider on water (the surface tension being measured by means of the attraction on a small disc) that the contaminating material on the surface could be squeezed up and concluded from her experiments that the water-surface can exist in two sharply-contrasted conditions; the normal condition, in which the displacement of the partition makes no impression on (the value of) the tension; and the anomalous condition in which every increase or decrease (of the surface) alters the tension.

The question was taken up again by Lord Rayleigh in 1899 (*Phil. Mag.* xlviii., 1899) with apparatus designed on the lines of that of Miss Pockels (but employing a different way of measuring the surface tension) and he concluded that the first drop in tension corresponded to a complete layer one molecule thick and that the diameter of a molecule of oil is about $1{\cdot}0\times10^{-6}$ mm.

Later investigations have been made by I. Langmuir (in America: *J. Amer. Chem. Soc.*, 1915 to 1918) and N. K. Adam (in England) and their coworkers. By measuring the surface area that can be completely covered by a weighed quantity of material Langmuir determined both the cross-sectional area and the length of a molecule and proved that the length for organic molecules like those of palmitic, stearic, cerotic acids, etc., was nearly five times the breadth, while in cetyl palmitate it is nearly ten times. Adam has developed the technique and has very much extended the theoretical interpretation (*Roy. Soc.*

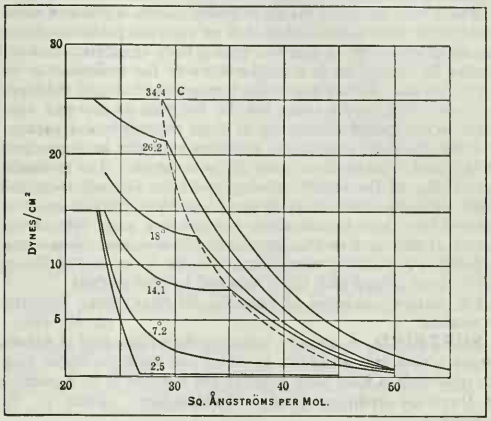


FIG. 11

Proc. A. 1921 to present time). Both Langmuir and he measured the amount of "oil" and measured directly the force required to compress the surface to any given area by means of a floating barrier. The actual force measured is the length of the barrier multiplied into the difference of the surface tension on the two sides of it. On the outside the surface is that of pure water—on the inside that of water on which a thin film has been formed. It is found that when the molecules in the film are so sparse as to be widely separated from one another the force due to the film is an expansive one.

This cannot be explained on Laplace's theory: it is necessary to modify it by allowing for the effects of thermal motion; the film in such a case is analogous to a two-dimensional gas. If the barrier is now moved so as gradually to compress the film various changes take place successively which are depicted in fig. 11 for the case of a film of myristic acid on weak HCl (N/100). The unit of area adopted is a square each side of which is an Ångström unit (*i.e.*, 10^{-10} metre), and the area specified is that occupied by one molecule of the acid. The ordinates of the curves are the difference of the tensions on the two sides of the barrier. The curves are isothermals extending from 2·5° to 34·4° C. They exhibit some of the characteristics of the p, v, curves for a condensible substance. At high temperatures the curves appear to be approximately rectangular hyperbolas. For small values of the area they approach the form for liquids. At intermediate stages, however, there is no constant pressure isothermal as in the analogous case of the vapour pressure of a liquid below the critical point (the form is more nearly that for the vapour pressure of a *mixture of two liquids;* this fact may indicate that the underlying water takes a part in the changes that occur).

It is not to be expected that there should be complete correspondence between the two classes of phenomena. There is, however, sufficient indication that the effects of thermal motions in the films cannot be neglected. The analogy with liquids and gases can be further illustrated by plotting FA against F, where F is the force applied per unit length; the resemblance to an Amagat diagram for a fluid is very striking (Schofield and Rideal, *Roy. Soc. Proc.* A, 109, p. 67; 110, p. 170). It is clear from the diagram that a film of myristic acid can be squeezed up until a molecule occupies less than 24 A^2. At the opposite end where the behaviour approaches that of a gas it is to be expected

that the equation would take the form $FA = RT$ where the value of R (allowing for only two degrees of freedom) should be 1.372 per molecule; at room temperature therefore FA should be about 400. This has been experimentally verified as a limiting value for very low surface pressures. With the long-chain fatty acids, esters and nitriles it is approached within 25%, the pressure being below 0.1 dyne per centimetre. With the dibasic ester $C_2H_5OOC.(CH_2)_{11}COOC_2H_5$ it has been verified within 10%.

The interpretation of the experimental results is still in a somewhat fluent state and it is clear that we must not press any *simple* gas analogy too far. A thin film upon a body of different material cannot be treated as in a similar state to the molecules in the body of a gas. Forces must exist between the film and the liquid beneath. This may account for the fact that at any rate some films do not spread indefinitely as a gas expands into a vacuum. Further, the most compressed state can only give an upper limit to the least cross sectional area of the molecule. The molecules are resting on the rapidly moving molecules beneath them and must share to some extent in their agitation. Still it must be granted that these investigations are throwing great light on the nature of films and on the dimensions of molecules. Where corroboration is possible, measurements made by means of X-rays are in good accord with those obtained by this method.

For certain properties of solutions *see* SOLUTIONS; THERMODYNAMICS. (A. W. Po.)

SURFBIRD, a stoutly built, sandpiperlike bird (*Aphriza virgata*), dark gray and white in colour and about ten inches long. Its relationships have been disputed but it seems to be a member of the snipe-sandpiper family (Scolopacidae), closest to the turnstones.

Its summer home is in the mountains of south central Alaska, where its nest, placed on rocky ground above timber line, was first discovered in 1926. In winter it lives along the Pacific coast of the Americas, from British Columbia to the Straits of Magellan. It feeds along the water line, preferring rocky or stormy shores where its favourite food, barnacles and mussels, is exposed at low tide. It is a rather quiet, inactive species, found in small flocks in winter, and is one of the lesser-known shore birds. (A. L. RD.)

SURF RIDING, a sport originating in Hawaii and now widely practised. For good surfing an open ocean exposure is required with a gently sloping bottom so that water depth at 100 to 1,000 yd. from shore, where the ride begins, is not over ten feet.

Where surf is light, flat boards four to six feet long by a foot wide, or air mattresses, ridden in a prone position, are used. For waves up to 20 ft. in height, and rides up to half a mile, a tapered hollow surf board 10 to 12 ft. long and 2 ft. wide, with a stabilizing fin near the back, is used. Body surfing without a board also is done. The rider first swims out to the point where the larger rollers peak up, but before the crest breaks. As the wave approaches him, he paddles his board toward shore to attain sufficient speed to start to coast down the face of the wave. Once he has caught the wave, he may rise to a standing position and ride it until it dies out near the beach. To increase speed and distance experts ride diagonally toward shore. (J. AN.)

SURGE, in general terms, is a sudden increase to an excessive or abnormal value and a fall from such a value subsequently. In meteorology, "surge" is the name applied to those long-period progressive changes of barometric pressure which occur simultaneously at many locations over a wide region and which are superimposed on short-period pressure fluctuations of a diurnal nature or variations caused by traveling atmospheric disturbances of a local character. A pressure rise or fall of two millibars in 24 hours that occurs simultaneously within an area of 3,000,000 sq.mi. corresponds to the order of magnitude of the phenomenon. Such pressure surges are commonly noted in regions close to the large semipermanent pressure centres of the earth such as the high-pressure area of the southern North Atlantic ocean. "Surge" is also a meteorological term often applied to a sudden increase in velocity of the large atmospheric wind streams, especially in the tropics. Such a wind surge occurs simultaneously over a large area and frequently spreads from place to place so that its progress can be followed on weather maps. In the trade-wind belts, meteorologists frequently refer to this event as the "surge of the trades" and, in the regions of the monsoon currents, as the "burst" or "surge of the monsoon." At a given location, an increase of wind speed from about 10 m.p.h. to 35 m.p.h. or more at all levels from the ground up to approximately 15,000 ft. can be expected in connection with a well-marked surge of the trades.

(D. C. McD.)

SURICATE (SLENDER-TAILED MEERKAT), a small South African mammal, *Suricata suricata,* belonging to the family that includes also the civet and mongoose. It ranges from Cape province to the Transvaal. The head and body are about 14 in. long and the tail half as much; the fur is long and soft, light grizzled gray in colour and banded with black on the lower part of the back. Suricates are sociable animals, living in holes in the rocks on the mountains and burrowing in the sandy soil of the plains. They feed chiefly on succulent bulbs, which they scratch up with long, curved, black claws on their forefeet. They are often domesticated as pets.

See CARNIVORE.

SURIGAO, a municipality and province of the Philippines. The province is on the northeast coast of Mindanao and includes the adjacent islands of Dinagat, Siargao and lesser isles. It lies within 10° of the equator so the climate is truly tropical. Surigao province with an area of 3,079 sq.mi., and a population (1960) of 359,997, is essentially hilly and mountainous with a narrow, often discontinuous coastal lowland. Surigao municipality, the provincial capital (pop. [1960] 37,439) has an average annual temperature of 80° F. and an annual rainfall of 144 in. with an average of 209 rainy days per year.

Agriculture is characterized principally as subsistance cropping by small landholders. In the mountains there is much shifting, rather than sedentary cultivation. The principal commercial products are copra, corn and abacá (Manila hemp). Both lumbering and mining are important industries with the largest sawmill at Bislig bay. Minerals include gold, iron ore and copper, but only gold was worked and its importance declined after 1950. Northeastern Surigao has one of the larger iron ore bodies of the world, but it is made up of discontinuous deposits and has both nickel and chromite impurities that have made it uneconomical to develop. (AN. C.)

SURINAM: *see* GUIANA: *Surinam.*

SURINAME, commercially the most important river in Dutch Guiana, South America, rises in the central forested area and flows 230 mi. to the Atlantic about 14 mi. below Paramaribo (*q.v.*), which stands on a shell reef on the west bank. Small ocean-going vessels may ascend about 37 mi. to Paranam and small motorboats about 100 mi. Beyond this are a number of rapids. There is an important source of bauxite at Paranam, 16 mi. upstream from Paramaribo. The most important tributaries are the Cottica and Commewijne which enter the estuary as a joint stream. A projected dam at Brokopondo will produce 150,000 kw. of electricity. (G. LN.)

SURINAM TOAD (*Pipa pipa*), a tongueless, tailless Amphibian (*q.v.*). It inhabits South America east of the Andes and north of the Amazon and is strictly aquatic, feeding largely on fish in quiet pools. It has an extremely flattened head; the snout and the angles of the jaws bear several loose skin flaps, the fingers of the forelimbs terminate in small star-shaped appendages and the eyes are minute and without lids. The hind limbs end in large fully webbed feet.

The eggs are carried on the back by the mother; the skin thickens and grows round the eggs until each is enclosed in a dermal cell, which is finally covered by a horny lid. The eggs may number about 100 and measure 5–7 mm. in diameter. They develop entirely within these pouches, and the young hop out as fully developed miniatures of the adult. Pairing takes place in the water, the male clasping the female round the waist. During oviposition the female extends from the cloaca a long bladderlike pouch, which the male carries forward between his breast and the back of the female. As each egg is released it is fertilized and attached by a natural adhesive to the female's back.

SURMA or BARAK, a river of Assam, India, and East Pakistan. It rises in the Barail range to the north of Manipur, its sources being among the southern spurs of Japvo. Thence its course is south with a slight westerly bearing, through the Manipur hills. The name Barak is given to the upper part of the river, in Manipur and Cachar. A short distance below Badarpur in Cachar it divides into two branches. The northern, which passes Sylhet, is called the Surma. The southern, which is called the Kusiara, subdivides into two branches, one called Bibiana or Kalni, and the other the Barak, both of which rejoin the Surma. At Bhairab Bazar in Mymensingh the Surma unites with the old channel of the Brahmaputra and becomes known as the Meghna until it joins the Ganges between Narayanganj and Chandpur.

The river is navigable by steamers as far as Silchar in the rains. The total length is about 560 mi.

SURPLICE, a liturgical vestment of the Christian church. It is a loose tunic of white linen or cotton material, with wide sleeves, worn as a choir vestment in the Roman Catholic Church (in which it is proper to all clerics) and as a eucharistic vestment in the Anglican Church and in some Lutheran and Free churches. The surplice appeared first in the middle ages, and it has no counterpart in the Eastern Churches. *See* also VESTMENTS, ECCLESIASTICAL.

SURPLUS WAR PROPERTY DISPOSAL (U.S.). Surplus war property disposal was first recognized in the U.S. as a special function in 1933 when the procurement division of the treasury department was assigned responsibility for disposing of the surplus property of World War I and even some property dating from previous wars. During World War II a virtually endless assortment of property of almost every description began to accumulate as surplus as the war developed and war requirements rapidly changed. The Surplus Property act of 1944, as amended in 1945, established a Surplus Property administration headed by a single administrator (previously a three-member board administered the act). An executive order effective Feb. 1, 1946, transferred the SPA's function to the War Assets corporation. Authority over surplus property abroad, however, became the responsibility of the state department. The War Assets administration, which succeeded the WAC on March 25, 1946, handled the entire disposal program for more than 90% of all surplus. Of the $27,100,000,000 worth of war surplus property declared to the War Assets administration, $25,600,000,000 had been disposed of by Oct. 1, 1949. In that year the WAA was abolished and its functions were transferred to the General Services administration for the express purpose of liquidation. (H. E. BY.; X.)

SURREALISM, a widespread revolutionary movement in the arts, promoted by the poet André Breton. The word itself was coined by the poet Guillaume Apollinaire, and the movement had its heyday, primarily in Paris, from 1918 to 1939, attacking tradition in all forms. It was an assertion of the belief that the world of the unconscious mind—as expressed by fantasies and dreams—has a reality superior to that of the phenomenal world. Surrealist expression aimed at a creative integration of both realities into a "super-reality." The theory owed much to the research of Sigmund Freud (*q.v.*), whose technique of probing the unconscious mind for the ultimate truth of human behaviour compares with the surrealist method of penetrating the depths of human personality to tap the inexhaustible sources of the imagination. In *Manifeste du surréalisme,* published in 1924 in Paris, Breton's own definition of surrealism was: "Pure psychic automatism, by which it is intended to express whether verbally or in writing, or in any other way, the real process of thought. It is the dictation of thought, free from any control by the reason and of any aesthetic or moral preoccupation."

Submission to mental promptings, appropriate as means of spontaneous writing, could apply only to the initial, conceptual phase of a painting. Since the movement was largely a literary expression, surrealist painting was, therefore, an illustrative art based on literary themes, using realistic and recognizable means and expressions. In abandoning rational, moral and aesthetic considerations, it echoed Dadaism (*q.v.*); but it was dissimilar in having a positive intention, namely to create a new, authentic vision of life by releasing dormant sensibilities. The release found infinitely varied expression in a fantastic art which, unprecedented as a movement, had affinities with the weird images of individual painters like Hieronymus Bosch (*q.v.*) or Giuseppe Arcimboldo. The emergence of surrealism in art was assisted directly by such notable pioneers as Kurt Schwitters, whose collages established strange relationships between disparate objects in juxtaposition; Marcel Duchamp (*q.v.*), whose "ready-mades" revealed the extraordinary significance of objects in abnormal contexts; and indirectly by Giorgio de Chirico, Paul Klee and Pablo Picasso (*qq.v.*). Exponents of surrealist art were Hans Arp, Salvador Dali (*q.v.*), Paul Delvaux, Jean Dubuffet, Matta Echaurren, Max Ernst, Morris Graves, René Magritte, André Masson, Joan Miró (*q.v.*), Francis Picabia (*q.v.*) and Yves Tanguy.

Surrealist expression also found outlet in literature (Jean Cocteau, Paul Éluard, Guillaume Apollinaire [*qq.v.*], and Louis Aragon), in sculpture (Alberto Giacometti) and in photography (Man Ray). The spirit of surrealism is also to be seen in advertising techniques where objects apparently unrelated are juxtapositioned.

SURRENDER (IN LAW), a mode of alienation of real estate. It is defined by Lord Coke to be "the yielding up of an estate for life or years to him that hath an immediate estate in reversion or remainder" (Coke upon Littleton, 337 b). It is the converse of release, which is a conveyance by the reversioner or remainderman to the tenant of the particular estate. A surrender was the usual means of effecting the alienation of copyholds (*q.v.*). A surrender was required, after the Real Property act, 1845, to be by deed, except in the case of copyholds and of surrender by operation of law.

In Scots law surrender of a lease is represented by renunciation. The nearest approach to surrender of a copyhold is resignation *in remanentiam* (to the overlord) or resignation *in favorem* (to a purchaser). These modes of conveyance were practically superseded by the Conveyancing act, 1874.

In the U.S. surrender divides itself into express surrender and surrender by operation of law. The former is the surrender known to the early common law; the latter takes place when the tenant and the reversioner have performed acts inconsistent with the continued existence of the two former distinct estates, from which acts the law implies that a surrender has been made. Thus where there is an acceptance by the tenant of a new lease to begin at any time during the existence of the previous lease, or the relinquishment of possession by the tenant and the resumption of possession by the landlord, a surrender by operation of law is deemed to have taken place.

SURRENDER (IN WAR) is identical in international law with capitulation and refers to agreements between commanders of belligerent forces for yielding a body of troops, a fortress, a district or a whole country. Surrenders, as opposed to armistices, are necessarily unequal (*see* ARMISTICE). According to the American Rules of Land Warfare (1940, art. 247) "capitulations should contain in precise terms every condition to be observed on either side, except such conditions as are clearly implied by the laws of war." Capitulations usually specify the precise moment when hostilities shall cease, the fate of the persons surrendered, the disposition of arms, the evacuation of territory, the care of the sick and wounded and the taking over of civil government.

Unconditional surrenders, such as that after the American Civil War of the Confederate forces under Gen. Robert E. Lee at Appomattox Court House on April 9, 1865, and of the German and Japanese forces after World War II, specify the moment at which hostilities shall cease, but, as they leave the victor wide discretion, establish unilateral powers rather than contractual relations. If applicable to all enemy forces they terminate the war and entitle the victor to deal with the enemy's territory, not as occupied under the limitations of the law of war, but as subjugated and capable of

annexation. Following the unconditional surrender of the German high command on May 8, 1945, the four Allied governments by a declaration of June 5, 1945, "assumed supreme authority in respect to Germany, including all the powers possessed by the German Government, the High Command and any state, municipal or local government or authority," but it was added that this "does not effect the annexation of Germany." "The Unconditional Surrender of all Japanese forces" demanded by the Potsdam declaration of July 26, 1945, was effected by Japanese acceptance of this declaration on Aug. 14, 1945, and the signature of a surrender instrument on Sept. 2, 1945. The Japanese emperor was permitted to govern "subject to the Supreme Commander of the Allied Powers." (Q. W.)

SURREY, EARLDOM OF. This earldom is of uncertain but unquestionably early origin. A Norman count, William de Warenne (*c.* 1030–88), is generally regarded as its first holder and is thought to have been made an earl by William II about 1088. William and his successors were styled earls of Surrey or Earls Warenne indifferently, and the family became extinct when William, the 3rd earl, died in 1148. The second family to hold the earldom of Surrey was descended from Isabel de Warenne (d. 1199), daughter and heiress of Earl William, and her second husband, Hamelin Plantagenet (d. 1202), an illegitimate half-brother of King Henry II. Their descendants held the earldom until Earl John died without legitimate issue in 1347.

The earldom and estates of the Warennes now passed to John's nephew, Richard Fitzalan, earl of Arundel (*c.* 1313–76), being forfeited when Richard's son, Richard, was beheaded for treason in 1397. Then for about two years there was a duke of Surrey, the title being borne by Thomas Holand, earl of Kent (1374–1400), from 1397 until his degradation in 1399. In 1400 Richard Fitzalan's son, Sir Thomas Fitzalan (1381–1415), was restored to his father's honours and became earl of Arundel and earl of Surrey, but the latter earldom reverted to the Crown when he died. In 1451 John Mowbray (1444–1476), afterwards duke of Norfolk, was created earl of Surrey, but the title died with him.

The long connection of the Howards with the earldom of Surrey began in 1483 when Thomas Howard, afterwards duke of Norfolk, was created earl of Surrey. Since then, with brief exceptions, the title has been borne by the duke of Norfolk.

See the articles NORFOLK, EARLS AND DUKES OF; and ARUNDEL, EARLS OF; also G. E. C.(ockayne), *Complete Peerage*, vol. vii. (1896).

SURREY, HENRY HOWARD, EARL OF (1517?–1547), English poet, son of Lord Thomas Howard, afterwards 3rd duke of Norfolk, and his wife Elizabeth Stafford, daughter of the duke of Buckingham, was born probably in 1517. He succeeded to the courtesy title of earl of Surrey in 1524, when his father became duke of Norfolk. His early years were spent in the various houses of the Howards, chiefly at Kenninghall, Norfolk; he used also to stay at Windsor with young Henry Fitzroy, duke of Richmond, of whom his father was guardian. Anne Boleyn tried to arrange a marriage between the princess Mary and her kinsman, Surrey. The Spanish ambassador, in the hope of detaching the duke of Norfolk's interest from Anne Boleyn in favour of Catherine of Aragon, seems to have been inclined to favour the project, but Anne changed her mind, and as early as October 1530 arranged a marriage for Surrey with Lady Frances de Vere, daughter of the 15th earl of Oxford. This was concluded at the earliest possible date, in February 1532, but in consequence of the extreme youth of the contracting parties, Frances did not join her husband until 1535. In October Surrey accompanied Henry VIII. to Boulogne to meet Francis I., and, rejoining the duke of Richmond at Calais, he proceeded with him to the French court, where the two Englishmen were lodged with the French royal princes. Surrey created for himself a reputation for wisdom, soberness and good learning. Meanwhile in spite of his marriage with Frances de Vere, the project of a contract between him and the princess Mary was revived in a correspondence between the pope and the emperor, but rejected by the latter. Surrey returned to England in the autumn of 1533, when the duke of Richmond was recalled to marry his friend's sister, Mary Howard. Surrey made his home at his father's house of Kenninghall, and took his father's side in a dispute which led to a separation between the duke and duchess.

In May 1536 he filled his father's functions of earl marshal at the trial of his cousins Anne Boleyn and Lord Rochford. In the autumn of that year he took part with his father in the bloodless campaign against the rebels in Yorkshire and Lincolnshire, in the "Pilgrimage of Grace." Hasty in temper, and by no means friendly to the Seymour faction at court, Surrey struck a man who insinuated that he had secretly favoured the insurgents. For breaking the peace in the king's domain he was arrested (1537), but thanks to Cromwell, he was merely sent to reside for a time at Windsor. During this retirement he had leisure to devote himself to poetry. In 1539 he was again received into favour. In May 1540 he was one of the champions in the jousts celebrated at court.

The fall of Thomas Cromwell a month later increased the power of the Howards, and in August Henry VIII. married Surrey's cousin, Catherine Howard. Surrey was knighted early in 1541, and soon after he received the Garter and was made chancellor of the duchy of Lancaster. In 1542 he was imprisoned again for quarrelling, but was soon liberated. Shortly after his release he joined his father on the Scottish expedition. They laid waste the country, but retreated before the earl of Huntly, taking no part in the victorious operations that led up to Solway Moss.

Surrey's ties with Wyat, who was fifteen years his elder and of opposite politics, seem to have been rather literary than personal. He appears to have entered into closer relations with the younger Wyat, with whom he got into trouble for breaking the windows of the citizens of London on Feb. 2, 1543. In prison for this offence he probably wrote the satire on the city of London, in which he explains his escapade by a desire to rouse Londoners to a sense of their wickedness. In October he joined the English army co-operating with the imperial forces in Flanders, and in the campaign of the next year he served as field marshal under his father, and took part in the unsuccessful siege of Montreuil. In August 1545 he was again serving in France.

Surrey had always been an enemy to the Seymours, whom he regarded as upstarts, and he thwarted the proposed marriage of his sister, the duchess of Richmond, with Sir Thomas Seymour. He thus increased the enmity of the Seymours and added his sister to the already long list of the enemies which he had made by his haughty manner and brutal frankness. He was now accused of quartering with his own the arms of Edward the Confessor. The charge was a pretext covering graver suspicions. Surrey had declared that his father, the duke of Norfolk, as the premier duke in England, had the obvious right of acting as regent to Prince Edward. He also boasted of what he would do when his father had attained that position. This boast was magnified into a plot on the part of his father and himself to murder the king and the prince. The duke of Norfolk and his son were sent to the Tower on Dec. 12, 1546. The duchess of Richmond was one of the witnesses (*see* her depositions in Herbert of Cherbury, *Life and Reign of Henry VIII.*, 1649) against her brother, but her statements added nothing to the formal indictment. On Jan. 13, 1547 Surrey defended himself at the Guildhall on the charge of high treason for having illegally made use of the arms of Edward the Confessor, before hostile judges. He was condemned by a jury, packed for the occasion, to be hanged, drawn and quartered at Tyburn. This sentence was commuted to beheading. Surrey was executed on Tower Hill on the 19th of the month.

Surrey's name has been long connetted with the "Fair Geraldine," to whom his love poems were supposed to be addressed. The story is founded on the romantic fiction of Thomas Nashe, *The Unfortunate Traveller, or Life of Jack Wilton* (1594), according to which Surrey saw in a magic glass in the Netherlands the face of Geraldine, and then travelled throughout Europe challenging all comers to deny in full field the charms of the lady. At Florence he held a tournament in her honour, and was to do the same in other Italian cities when he was recalled by order of Henry VIII. The legend, deprived of its more glaring discrepancies with Surrey's life, was revived in Michael Drayton's *England's Heroicall Epistles* (1598). Geraldine was the daughter of the earl of Kildare, Lady Elizabeth Fitzgerald, who was brought up at the English court in company with the princess Elizabeth. (*See* James

Graves, a *Brief Memoir of Lady Elizabeth Fitzgerald*, 1874.) She was ten years old when in 1537 Surrey addressed to her the sonnet "From Tuskane came my ladies worthy race," and nothing more than a passing admiration of the child and an imaginative anticipation of her beauty can be attributed to Surrey.

His poems, which were the occupation of the leisure moments of his short and crowded life, were first printed in *Songs and Sonettes written by the ryght honorable Lorde Henry Howard late Earle of Surrey, and other* (apud Richardum Tottel, 1557). A second edition followed in July 1557 and others in 1559, 1565, 1567, 1574, 1585 and 1587. Although Surrey's name, probably because of his rank, stands first on the title-page, Wyat was the earlier in point of time of Henry's "courtly makers." Surrey, indeed, expressly acknowledges Wyat as his master in poetry. His sonnets, his elegy on Wyat and his lyrics served as models to generations of court poets.

As their poems appeared in one volume, long after the death of both, their names will always be closely associated. Surrey's contributions are distinguished by their impetuous eloquence and sweetness, and he introduced new smoothness and fluency into English verse. His chief innovation as a metrician lies outside the *Miscellany*. His translation of the second and fourth books of the *Aeneid* into blank verse—the first attempt at blank verse in English—was published separately by Tottel in the same year *Certain Bokes of Virgiles Aeneis turned into English meter*.

Nott, *The Works of Henry Howard, Earl of Surrey* (1815); and *The Poetical Works of Henry Howard, Earl of Surrey*, Aldine edition (1866). The best account of Surrey's life is in Edmond Bapst's *Deux Gentilhommes-poëtes de la cour de Henry VIII* (1891), which rectifies G. F. Nott's memoir in many points. *See* also Brewer and Gairdner, *Letters and State Papers of Henry VIII*; Lord Herbert of Cherbury, *Life and Raigne of Kinge Henry the Eighth* (1649); J. A. Froude, *History of England*, ch. xxi and xxii; W. J. Courthope, *History of English Poetry*, vol. ii, ch. iii (1897), where the extent and value of Surrey's innovations in English poetry are estimated; F. M. Padelford, *The MS. Poems of Henry Howard, Earl of Surrey* (1906); O. Fest, "Über Surreys Virgilübersetzung," in *Palästra*, vol. xxxiv (1903).

SURREY, a southeastern county of England, bounded north by the Thames (separating it from Buckinghamshire and Middlesex), east by Kent, south by Sussex, west by Hampshire and northwest by Berkshire. The administrative county of London bounds Surrey on the northeast. Under the London Government Act 1963, Middlesex ceases to exist and the administrative county of London, with additional areas, becomes Greater London on April 1, 1965. On the same date Surrey gains the urban districts of Staines and Sunbury-on-Thames from Middlesex and loses to Greater London the boroughs of Barnes, Beddington and Wallington, Kingston-upon-Thames, Malden and Coombe, Mitcham, Richmond (which includes the Royal Botanic gardens at Kew), Surbiton, Sutton and Cheam, and Wimbledon, and the urban districts of Carshalton, Coulsdon and Purley, and Merton and Morden. Croydon (*q.v.*), the only county borough in Surrey, also becomes part of Greater London. (*See* LONDON.)

This article is concerned with the county of Surrey before the implementation of the above act. The geographical area of the county (including Croydon) is 721.6 sq.mi.

The north of the county adjoining the Thames is low lying and the soil consists largely of brick earth overlying London Clay. To the west, on the edge of the Thames basin, Bagshot sands outcrop at Chobham common, and Bagshot heath and Chobham ridges (400 ft.) are capped by plateau gravels. Across the middle of the county, from east to west, run the chalk North Downs. In the east they form a wide band, rising to a height of 852 ft., but westward they narrow into the Hog's Back. The line of the Downs is broken by the river Mole between Dorking and Leatherhead, and by the Wey at Guildford. These are the county's two chief rivers, and they join the Thames at Molesey and Weybridge respectively. To the south of the chalk Downs is a wide band of Lower Greensand, which narrows eastward. On this greensand is found the highest land in the county, Leith hill (965 ft.) near the centre, and Hindhead (895 ft.) in the west. The rest of the county, except for a small triangle of Hastings beds in the extreme southeast, is composed of Weald Clay. The National Trust owned 11,443 ac. in Surrey and protected 556 ac. in 1962. In 1958 about 160 sq.mi. in the Surrey hills were established as "an area of outstanding natural beauty" under the National Parks and Access to the Countryside act, 1949. At Wisley are the gardens of the Royal Horticultural society.

History.—Paleolithic implements were found in the gravel beds of the Wey, the Mole, the Wandle and the Thames (for example, near Farnham, Guildford, Godalming, Mortlake and Wandsworth), and at older gravel plateaus such as Warlingham and Wimbledon common. Here too, as at Blackheath near Albury, there is evidence of Neolithic man. Hoards of bronze implements have been found at a number of places. Iron Age earthworks cover a wide area and include mounds at Weybridge, Farnham, Holmbury and one, the largest of all, near Lingfield.

It was an area of forest, swamp, heath and open downland through which the Romans passed at the time of the invasion of Julius Caesar (55 B.C.), using perhaps the ancient track along the Downs, later known as the Pilgrims' way. Romanization, however, did not come until the time of the emperor Claudius (A.D. 43). For the next four centuries Surrey was ruled by the Romans and though Roman remains are relatively few, the largest settlements appear to have been at Southwark, Kingston-upon-Thames, Farley Heath near Albury and Woodcote near Croydon. Remains of about two dozen villas lie, for the most part, along the northern and southern edges of the Downs, and include that of Ashtead to the north and Titsey to the south.

The Thames was bridged at Southwark as part of Watling street, leading from Dover and Canterbury. Stane street, from Chichester to London, was probably not constructed till the 3rd century; it ran via Ockley, Dorking and Merton. No Roman town survived the Saxon settlement of Surrey, and there are few place names of Roman origin. Surrey was never an independent Saxon kingdom. The name itself means southern district. Nearly all place names are of Saxon origin, a large proportion pagan, such as Friday Street (commemorating the goddess Frea [Frigg]). The scantiness of the population is indicated by the small number of hundreds (14) compared with neighbouring counties. The tithings into which they were divided generally became parishes after the establishment of Christianity. Coronations of West Saxon kings at Kingston during the 10th century are referred to by chroniclers. A coronation stone is preserved there.

During the reign of Edward the Confessor, Godwin, earl of Wessex, and members of his family, including Harold, held many manors in Surrey. After the battle of Hastings (1066) William I took these for himself or for his Norman followers. Held back in Southwark from entering London, he turned southward to the Pilgrims' way. Domesday Book shows the extent of the ravaging of the Normans through Limpsfield, Godstone and Gatton, and then westward through Albury, Shalford and Farnham, along the road to Winchester. The bishop of Winchester retained Farnham.

Chertsey abbey, according to the 13th-century cartulary, was founded in 666 by St. Erkenwald who became its first abbot. During the Danish wars (*c.* 871) the abbot and monks were killed and the abbey burned. Refounded for Benedictines in the 10th century it maintained a prominent position and held many manors, including Chertsey, Egham, Thorpe, Chobham, Cobham, Epsom, Sutton and Coulsdon, until it was dissolved in 1537. Later foundations include the Cluniac priory of Bermondsey (1082), the Cistercian abbey of Waverley (1128), the Augustine priories of Merton (founded 1117), Newark (*c.* 1190), Tandridge (*c.* 1200) and Reigate (1220).

Even in the 13th and 14th centuries there probably was a strong contrast between the outlying forests and the suburban parts of Surrey. Southwark, Lambeth and Bermondsey with their great suburban houses of ecclesiastical dignitaries, sharing in the life of London. Kingston, with its bridge over the Thames, was a market town, as was Guildford with its manufacture of cloth. As elsewhere the ravages of the Black Death intensified commercial depression and religious agitation, which led to the Peasants' Revolt of 1381.

Sheen already had royal importance when Richard II pulled down the palace after the death of his first queen. Henry V rebuilt it, founding at the same time a Carthusian house. Following the insurrections of the 15th century Surrey under the Tudors became a county of royal residences. Henry VII rebuilt the palace of Sheen, renaming it Richmond. Henry VIII and Elizabeth I resided there, and Henry VIII received Hampton Court, just across the Thames, from Cardinal Wolsey. This brought court officials to the villages on the Surrey side. After the dissolution of the monasteries (1536–39) Henry began to build a flamboyant hunting lodge in Surrey, Nonsuch (near Ewell). This was built partly of materials from the dissolved priory of Merton and on the site of the village of Cuddington which he destroyed. Stones from Waverley abbey were used in building Loseley house, and Oatlands palace (Weybridge), now in ruins, had stones from Chertsey abbey. The manors of the religious houses fell into the king's hands or were sold by him or his successors. Reigate priory was granted to William Howard (later Lord Howard of Effingham; *see* HOWARD); and his son, who was commander in chief against the Spanish Armada (1588), is buried in Reigate church. No reference to the Tudors, and in particular to the reign of Elizabeth I, could ignore the theatres of Southwark, more especially Shakespeare's Globe.

In the middle ages sheep were important in rural Surrey and by the 16th century a cloth trade was growing, for example, at Guildford, Godalming and Farnham. Fuller's earth was already known at Nutfield and until the 19th century was used mainly in the woolen industry. In the 16th century iron smelting with charcoal in the Weald areas was further developed because of the demand for cannons. Charcoal was also needed in the manufacture of gunpowder. Powder mills were established before 1570 at Rotherhithe, Wotton, Albury and Chilworth (the latter closed only during the war of 1914–18), and at Godstone in 1589. Glassmaking at Chiddingfold flourished until the beginning of the 20th century; it may have begun during the Roman occupation.

Surrey, like London, was overwhelmingly parliamentarian during the Civil War. It was not a major battle ground, though there was fighting in the county, for example during the royalist reversals leading to the stand at Kingston common (July 7, 1648).

By 1653 the canalization of the Wey from Guildford to the Thames, planned by Sir Richard Weston of Sutton Place, was completed. This facilitated the transport to London of timber, grain, iron, gunpowder and the produce of market gardens. Daniel Defoe in the early 18th century described Farnham as the greatest corn market in England, London excepted, grain being brought along the Wey to be ground and then sent onward to London by water.

Surrey quarter sessions records which survive from 1659–60 contain numerous references to Quaker meetings and religious dissent generally. At the July sessions, 1665, during the plague, it was ordered that the wells at Epsom be locked for the summer to prevent strangers coming from London on pretext of drinking the waters, thereby carrying disease along the roads.

Samuel Pepys and John Evelyn, both Surrey men, have many references to the county in their *Diaries*, including Epsom at its height as a spa. It was then that horse racing on the Downs became fashionable. It was already possible to go from London for the day. John Evelyn was also a great gardener, expert on trees and pioneer planter of conifers.

In Surrey much land was enclosed before the 18th century. Market gardens were a feature in the west and along the Thames, as at Mortlake, at Mitcham, with its lavender and physic gardens, in Bermondsey and Camberwell. These gardens gave place to housing developments. Godalming and Guildford declined as industries moved to the Midlands or to Yorkshire. Maps of the 18th and 19th centuries show copper and iron, oil, grain, paper, snuff, and calico printing mills, mainly along the Wandle. Elsewhere were chalk, gravel and stone quarries, brickworks and lime kilns.

The middle decades of the 18th century saw the beginning of improved roads in Surrey, under turnpike trusts. Navigations included the improved canalization of the Wey as far as Godalming (1762); the Basingstoke canal (1796) originally constructed to link the industrial town of Basingstoke with the port of London; and the Wey and Arun canal (1816). The development of railways brought to an end the turnpike road system and canal building. The Surrey Iron railway, from Wandsworth to Croydon and then to Merstham, worked by horses and intended to convey materials such as chalk and stone to the Thames, was the first public railway sanctioned by parliament (1801). Freight was carried on payment of a toll. The first railway for steam trains to pass through Surrey was the London and Southampton, opened as far as Woking in 1838. This was followed by the London and Brighton in 1841. The railways brought the county, particularly north of the Downs, continually nearer to London and resulted in intense house building, as at Wimbledon, or at Caterham after the building of the Caterham Valley railway, sanctioned in 1854.

William Cobbett (born at Farnham, 1763) in his *Rural Rides* observes political and social conditions in the 1820s. These must be viewed against the background of the wars with France and shortage of wheat. A wet summer and poor harvest helped to intensify the crisis of the autumn of 1830. In 1848 the Chartist rising ended at Kennington common.

Until 1889 Surrey stretched along the south bank of the Thames as far east as Rotherhithe and embraced ancient parishes now in London, including Wandsworth, Lambeth, Camberwell and Southwark. These formed part of the hundred of Brixton. The Reform act of 1832 disfranchised three boroughs and divided the county into two divisions, each returning two members. Lambeth became a borough and was extended. Rotherhithe and Bermondsey were included in the borough of Southwark. Further changes were made by the Reform acts of 1867 and 1885. By the second act the boroughs of the northeast, including Southwark, Lambeth and Croydon, were divided into 17 single-member districts. Apart from Croydon (which became a county borough) these boroughs became in 1889 part of the new county of London and a new phase in the history of the county, with its administrative headquarters at Kingston, began.

Population and Administration.—At the 1961 census the population of the administrative county was 1,478,541. The population of the 13 boroughs was as follows: Barnes, 39,057; Beddington and Wallington, 32,603; Epsom and Ewell, 71,159; Godalming, 15,780; Guildford, 53,976; Kingston-upon-Thames, 36,461; Malden and Coombe, 46,572; Mitcham, 63,690; Reigate, 53,751; Richmond, 41,024; Surbiton, 62,977; Sutton and Cheam, 79,008; Wimbledon, 57,312. Of the 15 urban districts five had a population exceeding 50,000: Carshalton, 57,484; Coulsdon and Purley, 74,926; Esher, 60,610; Merton and Morden, 68,011 and Woking, 67,519.

The headquarters of the Surrey county council are at County hall, Kingston-upon-Thames. There were prior to the formation of Greater London in April 1965 13 boroughs (named above); 15 urban districts; and 5 rural districts containing 69 civil parishes. Assizes and quarter sessions are both held at County hall. Guildford and Croydon have separate sessions. There are magistrates' courts for 12 petty sessional divisions and also for the boroughs of Guildford, Kingston, Reigate and Richmond. The northeast of the county (as far west as Esher) is in the metropolitan police district. The Surrey constabulary, covering the rest of the county, is divided into eight divisions. The parliamentary constituencies in the administrative county under the Representation of the People act (1948), as amended, consist of 10 county constituencies and 7 borough constituencies.

Until the 19th century the county lay in the diocese of Winchester, apart from those parishes belonging to Canterbury. In 1905 the diocese of Southwark was created. Parishes which had previously been transferred to the see of London and those which in 1877 had been transferred to Rochester, were transferred to Southwark. In 1927 the west of the county passed to the new diocese of Guildford. Its cathedral, begun in 1936 and consecrated in 1961, stands on Stag hill. It was designed by Sir Edward Maufe and contains sculpture by Eric Gill (d. 1940). Croydon remains in the diocese of Canterbury. The development of the county has been greatly influenced by its proximity to London,

and its good transport facilities have made it attractive both as a residential and recreational area.

There are racecourses in the county at Epsom Downs, where "the Derby" is run, Sandown Park (Esher) and Lingfield Park; the All England Lawn Tennis club has its headquarters at Wimbledon; Bisley is a centre for rifle shooting; the headquarters of the Surrey County Cricket club is the Oval in Kennington, London, but some matches are played at Guildford.

Industries and Communications.—The total acreage under crops and grass in the early 1960s exceeded 180,000 ac. of which more than 110,000 were arable land. This represents about 25% of the total area (excluding water) of the county, compared with about 9% in 1939. Wheat and oats are the chief grain crops. The cattle are mainly of the dairy type. There are extensive market and nursery gardens in the fertile brick-earth plain beside the Thames and in the Bracklesham beds at Chobham and Bagshot.

The level land adjoining the main roads and railways attracted groups of miscellaneous industries along the Kingston bypass near Raynes Park and Tolworth, and also at Addlestone and Salfords. More recently there has been industrial development at Camberley. Kingston-upon-Thames and Weybridge are important centres of general engineering and aircraft industry, while miscellaneous industries in the Wandle valley at Mitcham, Merton and Hackbridge are the modern development of the old watermill industries for which the Wandle was once well known.

The main roads from London to Penzance, Portsmouth, Brighton and the south coast pass through Surrey which is served also by the Southern region main and suburban lines of British railways. London Transport underground extends to Morden, Wimbledon and Richmond. Bus and coach services cross the county. The civil airport at Gatwick was opened in 1958.

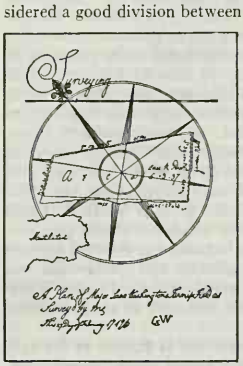
SURROGATE, a deputy of a bishop or an ecclesiastical judge, acting in the absence of his principal and strictly bound by the authority of the latter (Lat. *surrogare,* "to substitute for"). Canon 128 of the canons of 1603 lays down the qualifications necessary for the office of surrogate, and canon 123 the regulations for the appointment to the office. The office is of some importance in the United States as denoting the judge to whom the jurisdiction of the probate of wills, the grant of administration and of guardianship is confided.

SURTEES, ROBERT SMITH (1803–1864), English novelist and sports writer, was the second son of Anthony Surtees of Hamsterley Hall, Durham. Educated to be a solicitor, Surtees soon began to contribute to the *Sporting Magazine,* and in 1831 he published a treatise on the law relating to horses and particularly the law of warranty, entitled *The Horseman's Manual.* In the following year he helped to found the *New Sporting Magazine,* of which he was the editor for the next five years. To this periodical he contributed between 1832 and 1834 the papers which were afterward collected and published in 1838 as *Jorrocks's Jaunts and Jollities.* This humorous narrative of the sporting experiences of a cockney grocer, which suggested the more famous *Pickwick Papers* of Charles Dickens, is the work by which Surtees is chiefly remembered, though his novel *Handley Cross,* published in 1843, in which the character of "Jorrocks" is reintroduced as a master of foxhounds, also enjoyed a wide popularity. The former of these two books was illustrated by "Phiz" (H. K. Browne), and the latter, as well as most of Surtees's subsequent novels, by John Leech, whose pictures of "Jorrocks" are everywhere familiar and were the chief means of ensuring the lasting popularity of that humorous creation. Surtees wrote other novels, the last of which, *Mr. Facey Romford's Hounds* (1865), appeared after the author's death (March 16, 1864).

See R. S. Surtees, *Jorrocks's Jaunts and Jollities* (London, 1869), containing a biographical memoir of the author; W. P. Frith, *John Leech, His Life and Work* (2 vol., London, 1891); Samuel Halkett and J. Laing, *Dictionary of Anonymous and Pseudonymous Literature of Great Britain* (4 vol., Edinburgh, 1882–88).

SURVEYING is the science which has to do with the determination of the relative position or location of points on or near the earth's surface. This involves the art of measuring horizontal and vertical distances and of determining direction and angular relationships by the use of surveying instruments in the field. Extensive mathematical calculations are, quite often, a necessity along with the actual measurements. Information from the survey is generally portrayed graphically in the form of maps, charts, profiles, cross sections and other diagrams. Therefore, surveying in the field subsequently requires a considerable amount of computing and drafting.

Surveys may be classified in several different ways. Methods and instruments involved in surveying will vary considerably depending upon the magnitude and extent of the area and the purpose and use of the measurements. One method of differentiation involves a consideration of magnitude as to whether it is a plane or geodetic survey. The earth's surface which is very close to a sphere (actually a spheroid) has considerable curvature. In surveys of smaller magnitude involving limited areas or small parcels, the earth's surface is considered as a plane. In surveys of greater magnitude involving extended areas or surveys of whole states, countries or continents, account must be taken of this curvature. Special equipment and more precise equipment, procedures and calculations are involved. Sometimes an area of 100 sq.mi. is considered a good division between a plane survey and a geodetic survey. A second method of differentiation involves names which are descriptive of the particular function of the survey, such as land (or property) surveying, route surveying, topographic surveying, construction surveying, mine surveying, hydrographic surveying and geodetic (or control) surveying. These separate classifications will be discussed below. A third method of classification of surveys relates to the technical method or instruments used, such as transit-tape survey, stadia-azimuth survey, deflection angle survey, compass-chain survey, plane-table survey, trigonometric survey or photogrammetric survey. Precision denotes relative or apparent nearness to the truth, while accuracy denotes absolute nearness to the truth. The degree of accuracy is a ratio that expresses, in general terms, the accuracy attained or attainable in survey measurements. For example, a degree of accuracy of 1 in 5,000 indicates that there are errors in measurements amounting to one unit or less in each 5,000 units measured, or in the same proportion for a greater or lesser number of measured units. In horizontal distance measurement, the degree of accuracy is determined from the measured value and its probable error expressed as a ratio 1/distance. For a closed traverse it is usually expressed as the ratio of the linear error of closure to the total length of the traverse, $1/d$. For angular measurements in a traverse, it is usually expressed as the ratio of the angular closing error to the



BY COURTESY OF THE U.S. BUREAU OF RECLAMATION

FIG. 1.—A PLAN MADE BY GEORGE WASHINGTON IN 1746, INSCRIBED IN HIS OWN HANDWRITING

*Specifications for the Various Orders of Accuracy**

	1st Order	2nd Order	3rd Order
Triangulation:			
Base line length checks	1 in 25,000	1 in 10,000	1 in 5,000
Triangle closures, average	1 sec.	3 sec.	5 sec.
Triangle closures, maximum	3 sec.	5 sec.	10 sec.
Traverse:			
Closing error in position	1/25,000	1/10,000	1/5,000
Leveling:			
Closing checks	0.017 ft.$\sqrt{\text{mi.}}$	0.035 ft.$\sqrt{\text{mi.}}$	0.050 ft.$\sqrt{\text{mi.}}$
Closing checks	4 mm.$\sqrt{\text{km.}}$	8.4 mm.$\sqrt{\text{km.}}$	12 mm.$\sqrt{\text{km.}}$

*As approved by the U.S. Federal Board of Surveys and Maps, 1933.

square root of the number of angles, as $K\sqrt{n}$. For leveling it is expressed as the ratio of the error of closure in elevation to the square root of the horizontal length of the route in miles, as $K\sqrt{D}$. Prescribed standards have been established for various orders of accuracy as shown in the accompanying table. (K. S. Cs.)

History.—It is very probable that surveying had its origin in ancient Egypt. But long before the dynastic period in Egypt, the Neolithic man was probably able to make a rough kind of map based on his journeys, or a primitive plan to show tribal or property boundaries. Speculation is not needed. A plan of the villa of a great Egyptian noble was found in a Theban tomb of the 8th dynasty; in the tomb of one Menna at Thebes there is a representation on the walls of two chainmen surveying a field of corn; and in Ptolemaic and Roman papyri in the same country, measurements of plots of land are described. That the early Egyptians could carry out measurements with a considerable degree of accuracy is certain from a study of the dimensions of the Great Pyramid.

In Roman times the groma, which consists of two pairs of plumb lines suspended from the ends of two horizontal rods, at right angles to each other, was used to lay out lines at right angles. The metal parts of one of these gromas was found in 1912, in Pompeii. An early groma of the same type, but rougher construction, has been found in Egypt. The Romans also used 10-ft. rods, and bronze terminal pieces of such rods have been found at Enns, Aus., the foot in this case being 13.2 in. The Romans certainly made use of an instrument not unlike the plane table for determining the alignment of their roads. The Greeks used a form of log line for recording the distances run from point to point along the coast while making their slow voyage from the Indus to the Persian gulf about 325 B.C. Still earlier (as early as 1600 B.C.) it is said that the Chinese knew the value of the loadstone and possessed some form of magnetic compass. The earliest maps were based on inaccurate astronomical determination; not until medieval times, when the Arabs made use of the astrolabe, could nautical surveying really be said to begin. In 1450 the Arabs were acquainted with the use of the compass, and could make charts of the coast line of those countries which they visited. In 1498 Vasco da Gama saw a chart of the coast line of India, which was shown him by a Gujarati. Plane tables were in use in Europe in the 16th century and the principle of graphic triangulation and intersection was practiced by surveyors in England and elsewhere. In 1615 Willebrord Snell, the Dutch mathematician, measured an arc of meridian by instrumental triangulation.

The invention of printing and engraving in Europe in the 15th century and the age of the great discoveries which followed contributed much to the expansion of surveying and mapping activities. Modern developments in electronics, optics, photography, reproduction and aviation greatly influenced modern surveying. During World War II. the U.S. Army Map service and its affiliated organizations prepared more than 30,000 different maps and reproduced over 500,000,000 individual map sheets.

(C. F. A.-C.; H. St. J. W.; K. S. Cs.)

Horizontal Distance Measurement.—The distance between two points in surveying is understood to mean the horizontal distance. Frequently the slope distance is measured and is reduced mathematically to its horizontal equivalent before being used. Horizontal distances are reduced to sea level equivalent only in geodetic surveys. There are several methods of determining distances and the proper selection of the method to be used depends upon the cost, required precision and other considerations. The precision required on a reconnaissance would be quite different from that required on a horizontal control survey. The commoner methods of the pace, stadia, metallic tape, steel tape and invar tape are outlined below.

The method of pacing provides a rather rapid means of measuring, but yields results of a lower precision. The natural pace of an individual is usually about 27 to 30 in. and can be calibrated by pacing several times over a known distance. The natural pace is favoured over the artificial pace of three feet, especially over longer distances where the three-foot pace would be tiresome and hard to maintain. A passometer and pedometer are tally devices, similar to a watch in size, that can be strapped to the pacer and that register mechanically the number of paces taken or the distance directly in feet or miles. Distances obtained by pacing are not necessarily horizontal but are directly related to character of terrain. The usual precision of pacing is 1/100 to 1/200 and therefore is ideal for estimation, exploratory or reconnaissance work, rough mapping and checking other measurements.

The method of stadia is a rapid means of determining distance by an indirect method using the telescope of a surveying instrument and will be discussed under *Optical Distance Measuring Methods* below.

Tapes are made from several different materials, in various widths and lengths, and graduated in practically any manner desired. The most commonly used are metallic, steel and invar tapes. A metallic tape is made by weaving fine metal wires with cotton or linen threads into a tape which is waterproofed to prevent its stretching. It is usually $\frac{5}{8}$ in. wide, 50 to 100 ft. in length, and graduated in feet, tenths and half-tenths. Metallic tapes are principally used where a high degree of accuracy is not required and a light, flexible tape is desirable. Examples would be the cross sectioning for earthwork and the detailing for maps. The usual precision is 1/500 to 1/700. The steel tape is the most generally used method for direct linear measurement. It is made in a number of lengths, widths and thicknesses. The most commonly used length is 100 ft., but tapes are available in lengths of 50, 200, 300, 500 ft., in chain units and meter units. Most are $\frac{1}{4}$ or $\frac{5}{16}$ in. wide. Graduations in feet are generally feet and decimals. Steel tapes may be obtained with or without a reel and the usual precision of ordinary taping is 1/1,000 to 1/5,000; however, under proper conditions, precision taping can be accomplished at 1/10,000 to 1/30,000. Invar tapes are made of a nickel-steel alloy and therefore have a low coefficient of thermal expansion, approximately one-thirtieth that of steel. They are relatively soft and are easily kinked or broken. Invar tapes are used for the most accurate distance measurements made in surveying, such as base-line lengths for precise triangulation networks and city surveys. When properly used and adjusted, invar tape measurements can be made to a precision of 1/50,000 to 1/1,000,000.

Ordinarily taping on smooth level ground is accomplished by supporting the steel tape entirely on the ground, using taping pins as markers and counters, and using range poles to indicate the location of points and direction of lines. On uneven or sloping ground, the tape is held horizontal and a plumb bob is used to plumb vertically to the ground. Vertical positioning is accomplished by the use of a hand level. In precision taping, a number of precautions are followed and different techniques are employed. A number of factors affect the length of a tape and these factors can be either controlled or evaluated. These factors include standardization, temperature, slope, tension, sag, alignment, etc. A tape should be periodically compared with some permanent standard of length to determine its true length. The temperatures at which measured tape lengths are made are recorded and used in determining the temperature corrections. Spring balances are used to control the tension or pull which is applied and tension corrections are computed. Measurements are made on three-foot high stakes or bucks and vertical differences in elevations are obtained for computing slope corrections. The weight, length and tension of the tape are used for determining sag corrections. All of these corrections, when properly applied to the measured length of line, yield a measurement of high precision.

In years past, ordinary precision measurement was made with either an engineer's chain or a surveyor's (Gunter's) chain. The

engineer's chain was 100 ft. long and was composed of 100 links each 1 ft. long. The surveyor's chain was 66 ft. long and was composed of 100 links each 7.92 in. long. The surveyor's chain was a convenient unit of land measurement along with the rod, mile and acre units. Many modern land descriptions are still referenced with this unit. The terms chain and chaining have now mostly yielded to the terms tape and taping.

Other horizontal distance measuring devices include those that depend on observing the number of revolutions of a wheel. The mileage recorder on an automobile speedometer registers distances to 0.1 mi. with estimation possible to hundredths. A simple device for directly registering the number of revolutions of a wheel is an odometer and can be readily attached to any vehicle. When the circumference of the wheel is known, the relation between revolutions and distance is fixed.

Optical Distance Measuring Methods.—Distances measured optically depend upon the measurement of a length from a small base at one end and the angle subtended by that base at the other. The base may be fixed or variable and the subtended angle fixed or variable. The base may be at the observer's end or the far end and may be vertical or horizontal. Three examples of optical methods are stadia (tachymetry), subtense and range finder.

Stadia makes use of the telescope of the common surveying instrument. Two additional horizontal cross hairs are mounted on the reticule ring of a telescope. These are so spaced that the distance between the instrument and a distant point will be indicated by the intercept of the stadia hairs on a graduated rod held vertically on the point. Since the stadia hairs subtend a constant angle, the value of a stadia intercept is directly proportional to the distance between the observing instrument and the rod. The stadia interval factor is determined by the focal length of the telescope objective lens and the actual distance between stadia hairs and, for most modern instruments, is usually 100. On the external focusing-type telescope, an additional one-foot stadia constant must be applied. The usual precision of stadia is 1/300 to 1/1,000 and therefore useful in mapping, rough traverses and checking more precise measurements. On inclined sights, when the line of sight of the telescope is inclined upward or downward, the value of the vertical angle becomes a factor which is necessary to reduce stadia readings to horizontal and vertical distances. Stadia formulas, which have been derived, can be solved directly by special tables, by slide rules and by other special devices. A specially designed stadia arc is attached to some alidades and facilitates a rapid reduction of the stadia formula by eliminating the necessity of obtaining the vertical angle.

In the subtense method a bar or base of known length is arranged horizontally and the angle subtended is measured accurately by repetition procedures with a transit or theodolite. The subtense base may be of any convenient size. Sometimes signals are erected as ends of a subtense base as much as a quarter mile in length with the distance being taped. However, most subtense bars are specially designed instruments 6 to 20 ft. long. Subtense methods are mostly used in topographic and military surveying.

A range finder is an instrument consisting of a known base and arranged so that angles to a distant point are observed from the ends of the base and translated directly in distance units. The rangefinder principle has long been used in the military as a fire-control instrument.

Electronic Distance Measuring Methods.—With the advent of the electronic age, electronic methods were applied to the problems of distance measurement. The rapid development of radar during World War II as a navigational aid was quickly applied to peacetime uses in surveying long distances. Several of the radar systems which are of special note include shoran, loran, and Electronic Position Indicator (E.P.I.).

The geodimeter, a high-frequency light-signaling instrument, makes use of the speed of light in the determination of precise distances such as triangulation base lines longer than one mile. The distance is obtained indirectly by determining the time interval for a light beam to travel from the geodimeter to a distant plane mirror and return to the geodimeter.

The tellurometer is similar to the geodimeter but employs radio microwaves instead of light. Distances can be measured in daylight or darkness and in clear or foggy weather. The instrument is lightweight and portable.

Vertical Distance Measurement.—The difference in elevation between two points is the vertical distance between the two level surfaces in which the points lie. The elevation of a point is its vertical distance above or below an arbitrarily assumed level surface. The level surface used for reference is called the datum and the process of measuring vertical distances is called leveling. In considering the earth, a level surface is really a curved surface. Several techniques and methods are used including spirit leveling, trigonometric leveling and barometric leveling. Bench marks are fixed points of known elevation that are established at intervals throughout an area and provide permanent points of reference. Bench marks are usually referred to as mean sea level datum and are identified by metal caps set in concrete monuments, masonry walls, bridge abutments, rock outcrops or by spikes or large nails in poles or trees.

FIG. 2.—BENCH MARK TABLET USED IN THE UNITED STATES

In barometric leveling approximate differences in elevation can be determined by measuring the atmospheric pressure at the desired points using surveying altimeters. Atmospheric pressure varies inversely with the elevation of a point and thus these altimeters can be employed in making observations. However, barometric pressures do not remain constant and therefore precision measurements cannot be made. In order to detect these pressure changes, methods are used whereby observations are taken at a fixed station during the same period that other observations are made from point to point with a second altimeter. Barometric leveling is principally employed by reconnaissance or exploratory parties, especially in hilly or mountainous country.

Trigonometric leveling is an indirect method of determining differences in elevation by measuring vertical angles and slope or horizontal distances with the transit and using trigonometric calculations for reduction. Precision varies depending upon the instruments used, size of vertical angles and length of sights.

The most commonly used method for determining differences is a direct leveling procedure making use of a spirit level. A spirit level is used to fix the direction of a horizontal line of sight. The engineer's level, builder's level, hand level and precise level all make use of the spirit level principle. The engineer's level consists of a telescope which magnifies the image and provides a line of sight by means of intersecting cross hairs, a spirit level bubble vial which denotes the correct centred position, and a three or four foot-screw leveling head for adjusting the bubble, all of which are mounted on a tripod. The level vial and telescope are attached to a bar, which in turn is attached to a spindle. The telescope can be revolved only in a horizontal plane. When the instrument is properly adjusted and leveled, the line of sight in the telescope is horizontal. The telescope on the engineer's level is usually one which erects the image. The two types of engineer levels are the dumpy and the wye. In the dumpy level the telescope and bubble vial are rigidly attached to the instrument and in the wye level the telescope and vial are independent of the other parts of the instrument and may be lifted from the supports and turned end for end. The dumpy type is by far the more popular. The engineer level is used with a level rod for measuring differences in elevation. A level rod consists of a graduated 7-ft. wooden rod which can be extended to 13 ft. when needed. It is usually graduated with black markings on a white background in feet, tenths and hundredths. A sliding vernier target is used if the rod is to be read to thousands. Sometimes small spirit level vials are temporarily attached to the rod to ensure proper plumbing of the rod to vertical position. Differential leveling is the method of direct leveling used in determining differences in elevation. The level is

set up and leveled at a given position. A rodman holds the leveling rod alternately on the backsight and foresight turning points or bench marks and the levelman, operating the instrument, records the readings. The level and rod are moved alternately to new positions as the process is extended through an area. The difference between backsight and foresight rod readings yields a direct value for the elevation difference.

Spirit leveling methods are used extensively. The small builder's level is essential to setting construction grade stakes for building foundations, sewer lines and earthwork movement. The engineer's level is the most used level in all types of engineering work which require knowledge or control of the vertical dimension. The hand level is a hand-held metal sighting tube with plain glass covers at the ends with a level vial mounted on the tube which is used for rapidly measuring approximate differences. An Abney hand level is one mounted with a graduated arc for determining vertical angles. Precise leveling is accomplished with a precise level which usually has a three-screw leveling head, a telescope and bubble vial especially mounted so that they can be properly tilted with a tilting screw mounted under the eyepiece, a bull's eye level for approximate leveling, an optical-bubble viewer for observing the bubble from eyepiece position, and an optical system which gives improved sighting but with an inverted image. A precise level rod is about ten feet long and has a hardened-steel foot. It is graduated in metres, decimetres, centimetres or yards and decimals on a strip of invar metal fastened rigidly to the face of the rod and is inverted to correspond to the inverting of the telescope. The rod is equipped with a rod level and thermometer. Three cross-hair readings are taken on the front of the rod for each sighting and checked by reading other graduations on the back face.

A German-made self-leveling level was developed in 1950 which automatically levels by virtue of a pendulum-type arrangement of prisms, called a compensator, which always dampens down to the same position.

The "elevation meter," consisting of a three-wheeled trailer towed behind an automobile, was developed in the late 1940s. Distances are measured by revolutions of a wheel and inclinations with the vertical are measured by a pendulum. An electronic computer continuously multiplies and yields successive increments of elevation change. It has been successfully used in obtaining supplemental elevations.

Angular and Direction Measurement.—Angle and direction relationships are very important in surveying and can be expressed in a variety of ways and observed with several different instruments. Directions are expressed as bearings or azimuths which are referred to fixed reference lines. A reference line is called a meridian and can be either magnetic, true or assumed, depending upon its relationship to the earth's magnetic field, to the earth's north or south axis poles or to convenience. An azimuth is expressed as a horizontal angle measured clockwise from a reference meridian (north or south) and ranges in value from 0° to 360°. A bearing is expressed as a horizontal angle within a quadrant referred to a meridian. It is measured clockwise or counterclockwise, depending upon quadrant, from either north or south and ranges in value from 0° to 90°. A thorough knowledge of the intricacies of magnetic declination is desirable in understanding the relationships between the true and magnetic meridians.

Several methods are used in measuring angles depending on purpose, accuracy and convenience. Horizontal angles can be measured directly between two lines, can be measured by prolonging one line beyond point and observing deflection angle to the new line, can be observed directly on a compass box, or can be observed directly by carrying azimuths continuously on instrument. Multiple measurement of angles is desirable and these methods are referred to as repetition or direction. Instruments are available for making use of either basic method. The repetition method involves the use of a repeating instrument in adding successive observations of a horizontal angle by repetition and a mean taken to obtain an accurate measure of the angle. The direction method consists of measuring the direction to each station from one taken as the initial station. The angles are measured clockwise and the angle between any two observed stations is the difference of their directions.

Angles are commonly measured with the transit, but are also measured by means of the tape, compass, sextant, plane-table alidade and precise theodolite. The transit is referred to as a universal surveying instrument, because of the wide variety of uses for which it can be adapted. It may be used for measuring or laying out horizontal angles, directions, vertical angles, difference in elevation, distances and for prolonging straight lines. The essential features of a transit are a horizontal circle graduated in degrees which may be rotated and clamped in any position, a plate which rotates inside the graduated circle containing a vernier for accurate reading of the circle, and a telescope (line of sight) which is attached to and rotates with the vernier plate and also may be rotated vertically. The telescope is similar to that on an engineer's level. Verniers on most transits are so designed that the graduated circle can be read to the nearest minute, 30 sec., 20 sec. or 10 sec. The plates and telescope, mounted on four foot screws and tripod, are so manipulated that angles may be determined. A plumb bob attached to the centre of the instrument is used to assure centring over a station. In the 20th century the European-type transit has been increasingly used throughout the world. It essentially features a high degree of precision, an ease of operation, and compactness and lightweight. The horizontal and vertical graduated circles are read by means of an optical micrometer observed through an auxiliary telescope. All motions are enclosed and are dustproof and moistureproof. The instrument is mounted on a three-screw base and utilizes an optical plumbing device for centring over a point. Most models make use of a single eyepiece which means an inverted image. Measurements are generally made to the nearest minute of arc and the 0.1 min. by estimation.

The compass is an instrument which was formerly much used in land surveying, but, because of increasing accuracy requirements, has been replaced mostly by the transit. The compass, especially the hand compass, still has limited use in forest cruising, exploratory surveys and reconnaissance work. The modern transit has a compass attached and is used only as a check on transit work. The compass consists essentially of a circle graduated in quadrants from the north and south compass points to the east and west, with a magnetized steel needle mounted on a pivot at the centre, and counterbalanced for dip. Bearings can be read directly when the instrument is pointed on an unknown line.

The sextant, although principally used in navigation, is often employed in surveying to measure angles, especially in hydrographic surveying. The sextant is a hand-held instrument with a limb of one-sixth of a circle, but graduated and designed so that measurements can be made to 120°. Rays of light are reflected in order to span this large an angle. Angles may be measured while the observer is on a moving object, such as a launch from which soundings are also measured.

A tape is occasionally used in forming a triangle at the point to be measured and calculating the angle usually by trigonometry. Angles also can be determined graphically by means of the plane table and alidade. The essential features of a plane table are a drawing board mounted on a tripod and an alidade with a straight edge parallel to the line of sight. The alidade is essentially a telescope mounted on an upright standard and attached to a metal base which is used as a straight edge. The telescope can be rotated vertically and an arc permits reading the vertical angles.

The theodolite is a precision surveying instrument similar to the transit but larger and heavier in construction with a more finely graduated circle and more sensitive levels. Readings are made by means of micrometer microscopes to the nearest second of arc and by repetition and direction procedures to tenths. Because of the increased refinement needed in sighting the instrument, two closely spaced vertical cross hairs are employed. Theodolites are principally used in geodetic triangulation where precise angles are required and sightings are made on distant light signals at night.

Optical tooling is the application of surveying techniques and newly developed instruments to problems of shop measurement such as holding close tolerances in building large mock-ups and jigs, aligning shafts, setting surface plates, etc. With this new equipment measurements are made from a line of sight, vertical

plane and horizontal plane to accuracies of 0.001 in. by means of optical micrometers.

Triangulation.—Surveying procedures employ either the traverse method or the triangulation method. Both are employed extensively for setting up control for topographic surveys, land surveys and construction surveys. Triangulation consists essentially of a series of triangles in which many sides are common to adjacent triangles. All of the points or stations are occupied and the angles measured very carefully. The length of one base line in the system is also carefully measured. In trigonometry, if all the angles and one side of a triangle are known, the lengths of the remaining side can be computed. When one triangle is computed, the newly computed sides offer an entry into adjacent triangles and the process continues. Checks are made occasionally by comparing the computed distance with a new base line. Sometimes stations cannot be occupied, but angles from them can still be computed if the other two angles of the triangle in which they occur are measured. A triangulation arc system consists of a chain of figures, usually single triangles, polygons, quadrilaterals or some combination. A system over a broad area might take several of the above forms in a more or less irregular network scheme. After the angles are measured and the sides measured or computed, adjustments are made of the observations and computations are made of co-ordinates of the stations. The suitability of the figures depends to a great extent upon the shape of the figures selected. Angles near 0° or 180° are subject to large computational errors and are avoided when possible.

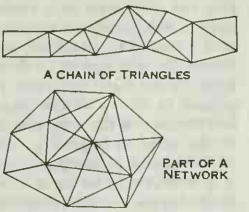


FIG. 3.—SYSTEMS OF TRIANGULATION

Traverse.—A traverse consists of a series of lengths and directions of straight lines between points, obtained by field measurements and used in determining positions of the points or stations. The lengths, as well as the directions, of all lines are field measured in contrast to the triangulation method. Traverses are classified and identified in a variety of ways. They are classified according to form, open or closed, depending upon whether the traverse is a long continuous one or one that closes on itself. Closed traverses provide checks on field work, where open traverses do not. Open traverses are used in highway or railroad preliminary lines and closed traverses are used in area or property surveys. Traverses are classified according to method used, as deflection-angle traverse, azimuth traverse, interior-angle traverse, etc. They are also classified according to instruments used, as transit-tape traverse, transit-stadia traverse, compass traverse, etc., and sometimes according to quality of results, as first-order traverse, second-order traverse, etc. Both triangulation and traverse methods afford convenient, precise and economical procedures for locating stations and the physical conditions involved usually dictate the method selected. Where the area is rough, hilly or swampy, obstructions probably forbid using a traverse. When stations have been located either by traversing or by triangulation, the details of a survey are referred to the traverse line or stations, and map plotting, area calculating, etc. can be continued.

Topographic Surveying.—A topographic survey is made for the purpose of determining the configuration or relief of the surface of the earth and of showing the location of natural and artificial features. A planimetric map presents only the horizontal positions of features and a topographic map shows the same features, but also presents the vertical position of features by showing relief in some measurable form. The form generally used is the contour which is an imaginary line on the ground, all points of which are at the same elevation above a specific datum surface, usually mean sea level. The contour or topographic map is an invaluable aid in most engineering construction projects, subdivision planning, military planning, industrial site selection and development of natural resources. Because of the wide range in the use of maps and the variation of the physical characteristics of different areas, there are several scales and methods used to develop the map. Large-scale mapping of small areas is usually rather simple in plan and execution, while small-scale mapping of extended areas is usually involved and difficult and is undertaken by the larger governmental or military agencies.

The aerial photograph is widely used in compiling maps and will be discussed separately later under *Photogrammetric Surveying*. Here only ground methods will be described. In compiling a topographic map, one should be thoroughly familiar with the characteristics of contour lines, imaginary lines of equal elevation. The proper choice of a contour interval, the vertical distance between contours, depends upon the scale, condition of terrain and intended purpose of the map. The construction of a topographic map involves setting up horizontal and vertical control over an area, locating detail and ground contour points and plotting the control, detail and contours on the map sheet. Horizontal control for an area usually consists of transit-tape or transit-stadia traverses or sometimes a triangulation system. Vertical control is established by differential leveling. The helicopter has added much to the ease of transportation in rough terrain.

In checkerboard mapping, the area is covered with a grid system of stakes set at the corner points and ground elevations determined at these grid corners and at essential intermediate locations with the level. The detail is also tied to the grid system and all of the data is located on the map sheet and the contours plotted. Regardless of the amount of control established and detail obtained, the compiler must do some freehand sketching to complete the contour lines. The checkerboard method is ideal for smaller areas where the terrain is gentle and a large-scale map is desired.

In transit-stadia mapping, points of a traverse or triangulation system are occupied and both the horizontal and vertical positions of the required detail and ground contour points are determined with a transit. The direction is usually recorded as an azimuth and the horizontal and vertical distances are measured by stadia. This data is transferred to the map sheet by paper protractor and scale and contours interpolated and sketched. Transit-stadia mapping can be accomplished over rougher terrain.

In plane-table mapping, the compilation is made directly in the field on the map sheet fixed on the plane table. The alidade takes the place of the transit and the directions and the horizontal and vertical distances are drafted directly on the sheet as they are observed. This sometimes eliminates the necessity of recording notes and also reduces the personnel needed on such an expedition. To use the plane table properly, one should understand the procedures of graphical traversing and triangulation and the principles of radiation, intersection and resection. Contours are sketched in the field where they can be viewed and not later in a drafting room. However, there are advantages and disadvantages for each method and there is no one better method, except as each individual job is considered. In order to test the accuracy of completed maps, test dimensions and test profiles are made and discrepancies analyzed. Contour maps are especially valuable in obtaining cross sections and profiles, determining earthwork quantities for grading operations, determining route locations, and areas and volumes of reservoirs. An excellent example of topographic mapping is the work accomplished by the United States geological survey in the task of preparing maps of the United States. The original plan was to map the country at a scale of 1:62,500 or 1:31,680. But with the increased use of maps and the increase in value of land and property, a scale of 1:24,000 has been adopted as standard for most regions. In most European countries, the governmental mapping has been completed; however, a continuing process of revision is necessary. Less than 2% of the land areas of the world are mapped adequately at a scale of 1:25,000 and less than 25% have reconnaissance maps at a scale of 1:250,000.

Route Surveying.—A route survey is made for the purpose of determining and laying out the lines and grades for linear construction of transportation and communication lines such as highways, railroads, pipelines, canals and transmission lines. Route surveying generally consists of determining the ground configuration and the location of objects, establishing the definite location of the route, and determining the necessary earthwork volumes.

Naturally, methods employed will vary somewhat between, say, a highway and a transmission line to be established between two end points. The typical sequence of operations involves a reconnaissance survey, preliminary survey, location survey and construction survey. The reconnaissance consists of an extensive general study of the area with a view toward selecting possible routes which might be feasible for further consideration. Maps and aerial photographs are useful to the locating engineer as he travels over the area by airplane, on the ground, or both. His cursory examination of the topography, physical features, distances, grades, vegetation and soils, will eliminate all but the better possibilities. From the economical standpoint, the reconnaissance is a highly important phase of the route survey. After one or two routes have been fixed for further study by the reconnaissance, a preliminary survey is begun. A narrow strip map is made of the country along the proposed route of sufficient width to make minor adjustments of location. The preliminary line is staked out on the ground with a transit and tape and the strip mapping completed by one of several methods. Elevations along the route are obtained with a level and are plotted to form a profile of the line. A profile is a vertical section along the ground surface. When these data are plotted, a centreline of the proposed route can be tentatively established on the map and is referred to as the paper location. The final line is calculated and the necessary curves computed. The final field location is then located on the ground by transit surveys, and cross sections and profiles are obtained with a level. These cross sections and profiles help to establish the final grade line and to indicate the amount of earthwork to be moved. Additional construction surveys are required to set grade stakes, slope stakes, alignment stakes and stakes for various structures such as bridges and culverts.

Mine Surveying.—Mine surveying includes underground surveying and mineral-land surveying. Underground surveying involves the survey operations performed beneath the earth's surface in connection with mining, tunneling, cave exploration and subterranean passageway construction. Underground surveys are essentially the same as surveys on the surface in that the purpose of the angle and distance measurements is to obtain the horizontal and vertical positions or co-ordinates of a point. However, underground surveys do differ in several ways. The station or point is usually in the roof instead of in the floor; the telescope, cross hairs and graduations must be artificially illuminated; distances are usually measured on the slope; and the transit tripod must have adjustable legs to work in low areas and on irregular or steep surfaces. The transit ordinarily used in underground work is the regular engineer's transit with an extension leg tripod and a prismatic eyepiece or an auxiliary telescope attached to one end of the horizontal axis or above the main telescope so that large vertical angles may be made for steep sightings. This side auxiliary telescope which is offset from the vertical axis causes an eccentricity and affects the observed values of horizontal angles. When the auxiliary telescope is mounted on top of the main telescope, the eccentricity affects the observed vertical angles. Mineral-land surveying involving location and patent surveys is essentially similar to land surveys on the surface involving the determination of land boundaries. Some differences arise because it is possible, by special laws, to obtain rights to subsurface mineral veins or lodes only.

Land Surveying.—Land surveying is one of the oldest branches of engineering known to man, the principles of which have been passed down through the centuries. Land surveys involve the original surveys to locate and monument the boundaries of property. Operations also include the preparation of a plat and a legal description of the limits of property and of the area included, the resurveys to recover and remonument property corners, and the surveys necessary when property is subdivided into smaller parcels. Property laws vary in different countries; however, the essentials of land surveying as practised in the various countries are similar in principle. The description of a parcel of land may take several forms such as describing by metes and bounds, by stating location and size in a rectangular system of land subdivision, by stating co-ordinates of property corners with reference to a plane co-ordinate system, or by reference to numbered lots on a subdivision plat. The primary function of the land surveyor is to carry out the field surveys; however, he must not only be familiar with the technical procedures but also with the legal aspects of property and boundaries. Land surveys are usually completed by the traverse method using a transit and tape and directions recorded as bearings. The precision required generally depends upon the value of the land. Formerly the surveyor's compass and chain were used extensively and many property descriptions in older deeds are recorded in those units. When a parcel of land is defined by giving the courses (directions) and lengths of all boundaries it is said to be described by metes and bounds. Such a description starts at a point of beginning, which is properly referenced by ties to witness objects, and, in turn, gives the bearing and distance of the sides around the parcel until it is closed back on the point of beginning. Many descriptions are of this type. In the opening of new public land for settlement and development, it is desirable to set up a better system of land subdivision. A good example is the development of the western part of the United States. Congress passed legislation establishing a rectangular system of surveys so that land could be systematically partitioned and transferred. The public lands were divided by true meridional lines and by parallels of latitude to form land townships approximately six miles square. Each township was subdivided into sections one mile square of approximately 640 ac. All 36 sections were numbered uniformly. Sections were further subdivided into half-sections, quarter-sections, etc. The principal line and standard parallel formed the initial point from which all land in the area was referred. Because meridians tend to converge when extended northward, the rectangular system was not the absolutely perfect system, as indeed no system would be on a sphere, and occasional correction lines were needed. A description of this type might be written: the northeast quarter of the southwest quarter of section 8, township 23 north, range 4 west, of the initial point of the second principal meridian in Indiana, containing 40 ac., more or less, according to the United States survey. Geodetic triangulation and traverse monuments of known geographic positions (latitude, longitude and azimuth) have been available, but computations were generally too involved to be used to any great extent as reference marks by land surveyors.

In the 20th century, plane co-ordinate systems have been developed for many states and countries. These grid systems involve relatively simple calculations and their use in describing tracts of land is increasing. Once the co-ordinates of the property corners have been determined, the boundaries may be relocated even though all corner monuments have been destroyed. The permanency of the co-ordinate system is obvious. Co-ordinates are generally not used by themselves but in conjunction with one of the other methods of description. In urban areas, land is subdivided in lots and numbered and may be legally described by reference to the recorded subdivision plat. The land surveyor is confronted by many legal problems such as the relocation of lost and obliterated corners, excess and deficiency, riparian rights, adverse possession, etc. Most states and countries require land surveyors to be registered, either directly or as a civil engineer.

Construction Surveying.—Construction surveys consist of the measurements necessary in the various stages of conceiving, planning, locating and erecting the many varied projects of construction. Such surveys are conducted to obtain data essential to the planning and cost estimating of a proposed project and to establish control points, lines and grades for construction operations. These surveys generally involve making a topographic survey of the site to be used in planning the structure, establishing on the ground a system of both vertical and horizontal control stakes to be used in making measurements of earthwork, giving line and grade as needed for construction and making final measurements to verify completed construction as a basis of payment to the contractor. On many projects, line and grade are conveniently given by the use of batter boards. Construction surveys are an integral part of the construction procedure in the building of highways, railways, airports, streets, bridges, culverts, tunnels, sewers, pipelines, canals, aqueducts, buildings, homes and dams, and generally involve the application of plane surveying.

Hydrographic Surveying.—In hydrographic surveying, surveys are made to determine the depth of water and configuration and character of bottom, the location of shore lines, rocks, shoals, reefs, lights and buoys, the direction and force of currents and the height and times of tides and water stages. The surveys are intended primarily for the preparation of nautical navigational charts, but are also used in planning and controlling engineering projects such as dams, reservoirs, tunnels, bridges, docks and other river and harbour improvements. In a sense, hydrographic surveying is quite similar to topographic surveying, the principal difference being that of locating points on the water surface, sometimes at great distance, and determining the depth of water at these points instead of elevations of land topography. The same horizontal control systems of triangulation or traverse are needed along the shore lines, and the same for vertical control in the form of bench marks. Shore line details of topography and prominent cultural features such as buoys and lighthouses are located by stadia or plane table so that these details might later be used as points of reference for range line and sounding work. The determination of depth of water at a point is made by soundings. Depths are referred to water level at the time of observation, but are later corrected to a desired datum which has been determined by tide gauge. Soundings are made by sounding rod, sounding line or fathometer. A sounding rod is used in areas where there are small amounts of current and depths up to three fathoms. A sounding line with attached lead and markers at intervals along the line has been popular. Increasing use is being made of the fathometer, an electrical echo-sounding device, which automatically records the depth by measuring the amount of time needed for an impulse of the sound from the ship to travel to the bottom and return as an echo. Some fathometers indicate depths on a lighted dial and others plot depths directly on graph paper, giving a continuing record as the ship moves along a predetermined course. Before the corrected soundings can be plotted on a map, their location with respect to the shore must be determined. Several methods are employed in determining this location, using range lines and angle measurement. Modern methods utilizing electronics are being increasingly used for position finding from two or more previously located shore stations. In shoran, loran, Decca and E.P.I., a radio impulse is sent out by the ship to the shore station and returned to the ship. The time elapsed between the two impulses can be measured to 0.00000001 sec. and, knowing the velocity of radio waves, the distance can be determined accurately. Several methods of plotting soundings on a map are used, depending on which of the foregoing methods was used. A three-armed protractor is useful in graphically solving the three-point problem.

A hydrographic map (or nautical chart) shows depths in fathoms (or feet for shoal areas) referred to mean low-water level and contours on land in feet above high water. A wire-drag procedure is used to find a near surface obstruction such as a reef or pinnacle rock. Current velocities are normally determined by the use of floats or one of a number of types of current meters. Current meters consist essentially of a propeller or a cupped wheel which revolves with the impact of flowing water and a counting device to indicate the number of revolutions of the wheel per time interval. Tide gauges, for measuring the height of the tide, are generally of the nonrecording type, such as the staff gauge and various types of float and pressure gauges requiring the presence of an attendant, and the automatic or self-registering gauge usually activated by a float which provides a continuous record of tidal variations with a passage of time.

Geodetic Surveying.—Geodetic surveys are necessary where the area is of such magnitude and the desired accuracy and precision is of such a high order as to require taking into account the curvature, figure and size of the earth. Surveys of this nature are of the highest calibre and generally form the basic framework of control, both horizontal and vertical, to which surveys of a lower order are tied. Therefore, many refer to them as geodetic control surveys. Basic horizontal control is established by precise first- and second-order geodetic triangulation and traverse. Basic vertical control is established by precise geodetic leveling. Both necessitate extremely precise instrumental equipment and observational techniques, capable and conscientious personnel and detailed computations. The resulting horizontal data are expressed in the form of geodetic latitudes and longitudes of definite established and monumented points and include distances and azimuths of all lines. Descriptions and geographic positions of these stations are available to the public and serve many useful purposes. This information provides the rigid framework for all types of mapping and charting, serves in locating national and other governmental boundaries, perpetuates the surveys of properly connected private boundaries, enables local surveys and maps to be tied to the national plan, provides a check in accuracy for local surveys and serves as a basis for many scientific studies such as earth movement, figure of the earth and geophysics.

An excellent example of a national geodetic triangulation net is that of the United States which is being performed by the U.S. coast and geodetic survey. The first surveys were along the Atlantic coast and then long transcontinental arcs were established across the country and tied together. Before computations could be finalized a datum was necessarily adopted and it was based on a point in Kansas known as station Meades Ranch. Geographic positions were adopted for this station and along with Canada and Mexico, the United States thus established the North American Datum. This network of first-order triangulation arcs is substantially completed and the areas between are to be covered by improved and standard classes of second-order work. Eventually such monuments will exist five or six miles apart throughout the country. In triangulation of such order, base lines must be measured with an invar tape and angles with precise theodolites. Base lines are measured as described previously with all the necessary precautions and corrections applied. Because of the distances involved the points occupied must be high to be intervisible. Stations are generally chosen on mountain peaks, hill tops and high ground, and towers must be built to elevate the instrument and to provide working space for the observing party. Many wooden stands are built; however, in flat plain areas, tall towers, of more than 100 ft., must be constructed. Steel towers, which can be relatively easily assembled, disassembled and transported, have revolutionized the speed of triangulation. Aluminum towers have been considered. The involved adjustments and computations of field data are the job of skilled mathematicians and computers. Precise traversing is essentially a series of connected base lines and is a part of a triangulation system augmenting the widely scattered triangulation stations. Precise first-order leveling forms the basic net for elevations or vertical control and is analogous to precise first-order triangulation, which forms the basic net for horizontal control. Precise leveling differs from ordinary leveling only in the sensitiveness of the instruments used, the care with which observations are made and the refinement of the computations. The result of first-order leveling is a network of leveling throughout a country with permanently set bench marks of known elevations above mean sea level. This allows the many surveying and civil engineering operations to be based on a common reference datum for purposes of co-ordination and comparison. Instruments used are the precise level and precise level rod which were previously described. Corrections for curvature of the earth and refraction of the air are necessarily applied. There are several methods of triangulation which are an outgrowth of scientific advances during World War II. One is shoran, an electronic method by which distance measurements are made by determination of the travel time of a radio signal. Observations are made by flying an airplane, equipped with the shoran transmitter-receiver-indicator units, across the line about midway between two ground stations equipped with shoran transponders. Several corrections must be applied to convert the shoran distance to geodetic ground distance. Accurate knowledge of the altitude, temperature, pressure and humidity are essential. Shoran is best suited for longer distances, 500 to 600 mi., and is particularly applicable in triangulation connection of continents and off-lying islands or where widely spaced area coverage is desirable. Another development is flare triangulation, a method of extending triangulation between points which exceed the sight limitations of ground means. The method depends upon height and intensity of the flare and clear weather visibility. It involves

several simultaneous radio-controlled theodolite observations on parachute flares dropped from an airplane about midway between stations. A third development is the Bergstrand geodimeter which is based upon the measurement of the travel time of a light wave to determine distances.

Photogrammetric Surveying.—Photogrammetry is the science or art of obtaining reliable measurements by means of photographs. ' Photogrammetric surveying is the application of photogrammetry to the determination of contours, dimensions, positions, etc., of parts of the earth's surface. The principles of photogrammetry are employed in many other scientific fields, but the greatest development has been in the field of surveying and mapping. It is not a new science, but only in the first half of the 20th century has the knowledge become general because of rapid developments in photography, optics and aviation. The type where photographs are taken from points on the ground surface is called ground or terrestrial photogrammetry. Aerial photogrammetry involves vertical or oblique photographs taken from an air-borne vehicle. Stereophotogrammetry means the use of overlapping pairs of photographs in a stereoscopic viewing or plotting device which gives a three-dimensional model for study. Terrestrial photogrammetry is quite similar to plane-table surveying with the camera replacing the plane-table. Modern phototheodolites of utmost precision can quickly record the terrain to be mapped. However, the process of conversion of a terrestrial photograph to the map plane is a cumbersome process and the view commanded by an air station is much preferred. A phototheodolite is especially advantageous in mountainous terrain where elevations are desired. The desired scale of a vertical photograph can be controlled or computed by the relationship of the flight altitude to the focal length of the aerial camera or by the relationship of a measured distance on the photograph to the corresponding distance on the ground. For surveying purposes, photography must give complete coverage of the area together with generous overlapping. Parallel flight strips are flown with usually 60% forward overlap and 30% side lap between adjacent strips. Most photography is made with a general purpose single-lens aerial camera, but there are some multiple-lens cameras that are used to considerable advantage in some types of aerial mapping. A vertical photograph of an area of perfectly flat terrain without any tip or tilt of the camera axis will yield an excellent perspective image of the area. Image points on photographs of irregular terrain are displaced caused by this relief and it is impossible to avoid this displacement. Very seldom is a photograph taken without some camera tilt or tip as the airplane attempts to fly its course, and therefore displacements of all points result. It is through measurements of these differences in scale and displacements in position that photogrammetrists are able to function. The displacement caused by relief and displacement caused by tilt afford the two major difficulties to be surmounted because these act from different points on the plane of the photograph. In addition, there are distortions of the image caused by photographic imperfections such as lens aberrations, film curvature, film shrinkage and camera movement during exposure. All of these factors—tilt, relief and photographic imperfections —make the task of preparing accurate topographic maps an involved and interesting problem.

One solution to the problems involved in aerial mapping is by method of radial-line plotting, which is accomplished by mechanical-armed templets, acetate templets or slotted templets. The positions of points in the radial-line method are plotted in their correct relative position to one another by a system of intersection and resection, using the radial centre of each photograph as the origin of the radials through the images of the points. This method is often referred to as graphical triangulation and there are some who prefer analytical methods of solution. The methods most commonly used in mapping make use of stereoscopic plotting instruments and the principle of stereoscopy. The problem of measuring vertical and horizontal dimensions in a stereoscopic model is overcome by using the principle of the floating mark. Many stereoscopic instruments have been developed and most serve well for some specific purpose. Some are simple, inexpensive and of low accuracy, and others are intricate, expensive instruments of the highest precision. In solving the problems of tilt and relief displacements, each instrument uses the same general method although there is wide difference in mechanical details. A pair of overlapping photographs or diapositives is mounted in the instrument to recover the relative orientation of the negatives at the instant of exposure. A miniature model of the terrain is created and is viewed by a stereoscopic viewing system. The model is brought to the desired scale and oriented to the proper datum as provided by ground-survey control points. Map detail and contours are transferred to the manuscript sheet by use of the floating mark. The model re-created accurately, as it would appear in nature, automatically solves the problem of tilt and relief displacements. Some of the instruments used are the sketchmaster (nonstereoscopic), KEK plotter, contour finder, stereocomparagraph, multiplex, Kelsh plotter, Balplex, stereoplanigraph, aerocartograph, stereotopograph and autograph. Problems of photographic imperfections have not been altogether solved and much research remains in this area.

Even though photogrammetry is over 100 years old, it was only after World War II that it had profound influence on the economics of surveying and mapping. The plane table, as the basic procedure for making topographic maps, has been replaced by photogrammetric methods. Ground surveys are still needed in considerable number, but in major mapping operation the field operations are supplemental to the photogrammetric operations.

"SURVILLE, CLOTILDE DE," the supposed author of the *Poésies de Clotilde.* The generally accepted legend gave the following account of her. Marguerite Éléonore Clotilde de Vallon Challis, dame de Surville, was born in the early years of the 15th century at Vallon. In 1421 she married Bérenger de Surville, who was killed at the siege of Orleans in 1428. Her husband's absence at the war inspired her heroic verses and his death her elegiac poems. The last of her poems is a *chant royal* addressed to Charles VIII. In 1803 Charles Vanderbourg published as the *Poésies de Clotilde* some 40 poems dealing with love and war. Research showed that the documents, communicated by the marquis de Surville to Vanderbourg, were not genuine, and the account of Clotilde herself was proved to be inaccurate.

SUSA (SHUSHAN, SHUSH), capital of Susiana (Elam) and chief residence of Darius I and his successors. It lay under the Zagros range at about lat. 32°, near the bank of the Karkheh (Choaspes) river and close to the Karun. (For early history *see* ELAM.)

The site, identified (1850) by W. K. Loftus, has on it four mounds. One, rising about 38 m., holds the citadel. A second to the east represents the palace of Darius I and was excavated by M. Dieulafoy. The enameled bricks taken from its walls are in the Louvre, Paris. A third mound to the south contains the royal Elamite city, while the fourth mound consists of the poorer houses. Excavation of the citadel was begun by J. de Morgan in 1897. It yielded the obelisk of Manistusu, the stele of Naram-Sin and the code of Hammurabi (the latter in the winter of 1901–02). (*See* BABYLONIA AND ASSYRIA; IRAN: *Archaeology.*)

The finest pottery came in the lowest strata, 25 m. below the surface, and belongs to two different civilizations, both in the Neolithic period. The earlier is characterized by vases of fine red clay, wheel-made, in a few well-defined shapes, and all with thin, polished sides. The decorations applied in black paint or red-brown ferruginous earth consist of bold geometrical patterns, often combined with spirited studies from nature. The pottery of the second period shows a retrogression, being coarser and porous.

Above the early strata come remains of Elamite and early Babylonian civilizations, inscribed objects from the latter bearing pictorial characters from which the cuneiform was evolved. The upper portions of the mounds disclosed inscribed Achaemenian

monuments, Greek pottery and inscriptions of the 4th century B.C., coins of the kings of Elam and Parthian and Sassanian relics. Moslem tradition says that the tomb of the prophet Daniel lay in the bed of the Karkheh river and a mosque was built on the bank opposite the supposed spot. Until after the 14th century the city was a flourishing centre of a district famous for silk, sugar cane and oranges.

SUSO (SEUSE), **HEINRICH** (*c.* 1296–1366), Swabian mystic, was born at Überlingen on Lake Constance, Ger., or, possibly, at Constance itself. At the age of 14 he joined the Dominican order in Constance where, five years later, he underwent a religious experience that gave a lasting and distinctive character to his spiritual life: all marked by his self-dedication, made at that time, to the Eternal Wisdom. (Testimony of the so-called *Life of the Servant* concerning the early decades of his religious life is open to serious reserves.) Sometime before 1327 he went to Cologne for further theological studies and, together with Johann Tauler, was a pupil of Meister Eckhart (*qq.v.*). His first work, the *Little Book of Truth* (*c.* 1329), was occasioned by the controversies stirred up by the trial of his teacher. About ten years later he composed in Latin the *Horologe of Wisdom*, the most durably popular and influential of his writings. The *Little Book of Eternal Wisdom* (of which, at one time, the *Horologe* was thought to be a free translation) seems to come from the period of his maturity about 1348. The most attractive of the Rhineland mystics and the easiest to comprehend, Suso presents a doctrine, Neoplatonic and Thomist, which in orientation is Eckhartian but in content quite his own.

He died at Ulm on Jan. 25, 1366. He was beatified in 1831, and his feast is celebrated on March 2.

The most reliable text of the German writings is that established by K. Bihlmeyer, *Heinrich Seuse: Deutsche Schriften* (1907); of the *Horologe* it is *Colloquia Dominicana . . . a Beato Henrico Susone dictata* (1923). The best translations are those of J. M. Clark: *The Life of the Servant* (1952) and *Little Book of Eternal Wisdom* and *Little Book of Truth* (1953).

See C. Gröber, *Der Mystiker Heinrich Seuse* (1941); J. A. Bizet, *Henri Suso et le déclin de la scholastique* (1946); J. M. Clark, *The Great German Mystics*, pp. 54–74, with bibliography, pp. 114–117 (1949). (E. O'B.)

SUSQUEHANNA, the longest river in the eastern United States, rises in Otsego lake, central New York, and flows southwestward into Chenango county, N.Y., where it heads southward into Susquehanna county of northeastern Pennsylvania. The river then changes its direction northwestward and enters south-central New York for a short distance before again turning southward into Bradford county, Pa. After flowing southeastward through the Allegheny plateau it enters the Ridge and Valley province north of Wilkes-Barre and changes its course southwestward, following one of the major longitudinal valleys. At Sunbury this part of the river, called the North Fork, is joined by the West Branch. The stream then turns southeastward, crossing five ridges and forming water gaps, after which it traverses the Piedmont plateau and empties into Chesapeake bay at Havre de Grace, Md.

Prior to the Pleistocene ice age the Susquehanna drained most of central New York state, but due to morainal deposits across the state the northern tributaries were blocked. At the mouth of the Susquehanna a submarine channel extending eastward across the Continental Shelf indicates the presence of the former valley of the river.

The West Branch of the Susquehanna, 160 mi. in length, rises in the Allegheny plateau of Indiana county, west-central Pennsylvania. The river flows northeastward to Williamsport and then turns southward to Sunbury. The North Fork falls 1,923 ft. and the West Branch falls 688 ft. The major tributaries are the Chemung and Juniata rivers.

Important cities on the Susquehanna river are Binghamton, N.Y., and Wilkes-Barre, Berwick, Sunbury and Harrisburg, Pa. Williamsport is the major city of the West Branch. Due to rock obstructions and rapids the Susquehanna is not navigable; an abandoned canal at its mouth once made the river navigable for a short distance. The Susquehanna presents the greatest waterpower potential of rivers in the eastern United States. There are hydroelectric power plants at Holtwood and Safe Harbor, Pa., and Conowingo, Md. (E. W. MI.)

SUSSEX, EARLS OF. The early history of the earldom of Sussex, an English title, is involved in some obscurity, owing to the fact that under the Norman kings titles of earls were often indifferently derived from a county, from its chief town or from the earl's principal residence, although the distinctive mark of an earl was deemed to be his right to "the third penny" of the pleas of a county (*see* EARL).

Thus in the 12th century the same person is sometimes found described as earl of Sussex, sometimes as earl of Chichester and sometimes as earl of Arundel, while the inclusion of the counties of Sussex and Surrey under the jurisdiction of a single sheriff led at one time to even further confusion. The difficulty was increased by the crown's admission in 1433 that the possession of the castle of Arundel carried with it the right to the title of earl of Arundel, though a later investigation proved the invalidity of the claim.

The Complete Peerage I (ed. 1910), 231–2, holds that Roger de Montgomery, who received grants from William the Conqueror of a large part of the county of Sussex, including the city of Chichester and the castle and honour of Arundel, besides lands in Shropshire with the castles of Shrewsbury and Montgomery, "may be considered" the first earl of Sussex. Whatever his titles were, they were forfeited to the crown when his son Robert was attainted in 1102, and the forfeited estates were conferred by Henry I on his second wife Adelicia, who after Henry's death married William de Albini, or d'Aubigny. The latter was created earl of Sussex by King Stephen in 1141, and "the third penny" of that county was confirmed to him by an instrument of the reign of Henry II, in which, however, he is styled earl of Arundel, a designation by which he was more generally known. His grandson William, 3rd earl of Sussex, was one of King John's sureties for the observance of Magna Carta; and in 1243, the earldom reverted to the crown on the death of Hugh de Albini, 5th earl of the line. His wife, the daughter of the earl of Surrey, held the estates of the earldom in her dower and after her death her brother, and his successor, John de Warenne (1286–1347), earls of Surrey, were sometimes incorrectly called earl of Sussex. (*See* ARUNDEL, EARLS OF.)

Ratclyffe Earls.—For nearly 200 years, from 1347 to 1529, the title of earl of Sussex did not exist in the English peerage. In 1529, however, it was conferred on Robert Ratclyffe (Radcliffe, Radclyffe: *c.* 1483–1542), who had been made Viscount Fitzwalter in 1525. In 1540, Ratclyffe was appointed great chamberlain of England. With Edward, the 6th earl of the Ratclyffe creation (*c.* 1552–1643), the title became extinct.

Savile Earls.—In 1644 Thomas Savile (1590–*c.* 1659), son of John Savile, 1st Baron Savile of Pontefract (1566–1630), was created earl of Sussex. Savile opposed Thomas Wentworth, afterward earl of Strafford, the rivalry between the Saviles and the Wentworths being of long standing in the history of Yorkshire. During the Great Rebellion Savile played a double game, and was imprisoned at different times by both parties. His later years were

spent in retirement at Howley Hall, where he died about 1659. He was succeeded in the earldom of Sussex by his son James, on whose death without issue in 1671 the title became extinct.

It was revived in 1674 in favour of Thomas Lennard, 15th Baron Dacre, whose wife Anne (d. 1722) was a daughter of the famous duchess of Cleveland by King Charles II, and the title again became extinct at this nobleman's death in 1715. The title was next conferred in 1717 on Talbot Yelverton, 2nd Viscount de Longueville and 16th Baron Grey de Ruthyn (1690–1731), from whom it descended to his two sons successively, becoming once more extinct on the death of the younger of these, Henry (b. 1729) in 1799.

Royal Earls.—In 1801 Prince Augustus Frederick (1773–1843), the sixth son of George III, was created duke of Sussex. Spending his early years abroad, the prince was married in Rome in 1793 to Lady Augusta (d. 1830) daughter of John Murray, 4th earl of Dunmore. The ceremony was repeated in London and two children were born, but under the Royal Marriage act of 1772 the Court of Arches declared the union illegal. The children took the name of d'Este. Sussex was a man of liberal ideas; he favoured the abolition of the slave trade, the repeal of the corn laws and the removal of the civil disabilities of Roman Catholics, Dissenters and Jews. His second wife, Cecilia, widow of Sir George Buggin, was created duchess of Inverness in 1840. He died at Kensington palace on April 21, 1843. The older title of earl of Sussex was conferred in 1874 upon Prince Arthur, the third son of Queen Victoria, who at the same time was created duke of Connaught and Strathearn. At the death of his grandson, who had succeeded to the titles in 1942, in 1943, it became extinct.

SUSSEX, THOMAS RADCLIFFE or RATCLYFFE, 3RD EARL OF (*c.* 1525–1583), was lord lieutenant of Ireland and lord lieutenant of the north under Queen Elizabeth I. The eldest son of Henry, 2nd earl of Sussex, by his first wife, Elizabeth, daughter of Thomas Howard, 2nd duke of Norfolk, he was born about 1525, and after his father's succession to the earldom in 1542 was styled Viscount Fitzwalter. After serving in the army abroad, he was employed in 1551 in negotiating a marriage between Edward VI and a daughter of Henry II, king of France. His prominence in the kingdom was shown by his inclusion among the signatories to the letters patent of June 16, 1553, settling the crown on Lady Jane Grey; but he nevertheless won favour with Queen Mary, who employed him in arranging her marriage with Philip of Spain, and who raised him to the peerage as Baron Fitzwalter in Aug. 1553. In April 1556, Fitzwalter was appointed lord deputy of Ireland. The measures enjoined upon Fitzwalter by the government in London comprised the reversal of the partial attempts that had been made during the short reign of Edward VI to promote Protestantism in Ireland, and the "plantation" by English settlers of that part of the country then known as Offaly and Leix. But Fitzwalter first of all found it necessary to make an expedition into Ulster. Having defeated Shane O'Neill and his allies the MacDonnells, the lord deputy, who by the death of his father in Feb. 1557 became earl of Sussex, returned to Dublin, where he summoned a parliament in June of that year. Sussex then took the field against Donough O'Conor, whom he failed to capture, and afterward against O'Neill, whose lands in Tyrone he ravaged, restoring to their nominal rights the earl of Tyrone and his reputed son Matthew O'Neill, baron of Dungannon. (*See* O'NEILL.) In June of the following year Sussex turned his attention to the west, where the head of the O'Briens had ousted his nephew Conor O'Brien, earl of Thomond, from his possessions, and refused to pay allegiance to the crown; he forced Limerick to open its gates to him, restored Thomond, and proclaimed Donnell O'Brien a traitor. He took part in the ceremonial of Queen Elizabeth I's coronation in Jan. 1559; and in the following July he returned to Ireland with a fresh commission, now as lord lieutenant, from the new queen, whose policy required him to come to terms if possible with the troublesome leaders of the O'Neills and the MacDonnells. Sussex was recalled, at his own request, in Oct. 1565. His government of Ireland had not, however, been without fruit. Sussex was the first representative of the English crown who enforced authority to any considerable extent beyond the limits of the Pale.

On his return to England, Sussex immediately threw himself into opposition to the earl of Leicester. In 1566 and the following year Elizabeth employed him in negotiations for a marriage with the archduke Charles. When this project failed Sussex returned from Vienna in March 1568. In July he was appointed lord president of the council of the north and in 1569 lord lieutenant of the north in which office he had to deal with the rebellion of the earls of Northumberland and Westmorland. In 1570 he laid waste the border, invaded Scotland, and raided the country round Dumfries, reducing the rebel leaders to complete submission. In December he became a privy councillor and in July 1572 lord chamberlain. He was henceforth in frequent attendance on Queen Elizabeth, both in her progresses through the country and at court. He favoured her proposed marriage to Francis, duke of Anjou, and was an advocate of a conciliatory policy toward Spain. He died in London on June 9, 1583.

The earl of Sussex was a patron of literature and of the drama. He was twice married: first to Elizabeth, daughter of Thomas Wriothesley, earl of Southampton; and secondly to Frances, daughter of Sir William Sidney. His second wife was the foundress of Sidney Sussex college at Cambridge, which she endowed by her will. The earl left no children, and at his death his titles passed to his brother Henry. (R. B. WM.)

SUSSEX, a county of southern England bounded on the south by the English Channel, on the west by Hampshire, and on the north by Surrey and in part by Kent, which bounds it on the east. The geographical area is 1,457 sq.mi. (3,774 sq.km.).

Physical Geography.—From the chalk hills of the western border, the South Downs (average height 500 ft. [150 m.]; Ditchling Beacon, 813 ft. [248 m.]) lead east-southeast to meet the sea between Brighton and Eastbourne as bold cliffs, notably Beachy Head. Farther east, between the rich alluvial pastures of Pevensey Levels and Walland Marsh (part of Romney Marsh), the Hastings Sands reach the sea, stretching back in a broken range northwest to the Forest Ridge of Ashdown Forest (837 ft. [255 m.] at Crowborough) and St. Leonard's Forest. The South Downs slope gently to the south, with zones of greensand and gault leading to a belt of fertile brick-earth loam extending from near Shoreham-by-Sea to Hampshire and broadening out south of Chichester into the flat headland of Selsey Bill. The northern slopes of the Downs are abrupt, and there the greensand and gault belts lead to the heavy clay of the Weald (*q.v.*). The coastline has changed within historic times, the land being constantly eroded by the sea, particularly around Selsey, where the site of the Saxon cathedral is now probably a mile out to sea. The lagoon of Pagham Harbour was partly reclaimed at an early date but was inundated by the sea about 1300, recovered in 1876, and again lost to the sea in 1911. The drift of shingle tends to force eastward the mouths of the rivers that rise in the Forest Ridge and flow south through gaps in the Downs, but new outlets have in some instances been made by storms, as at Newhaven in *c.* 1590, or by dredging, as at Shoreham-by-Sea in 1815. Wide deposits of shingle now separate the sea from the medieval ports of Winchelsea and Pevensey. (L. F. S.)

Archaeology.—The influence of geology on the distribution of human activities at different stages of culture is striking, and Sussex has an important record of prehistoric sites and discoveries. The Paleolithic period is poorly represented, especially since the Piltdown discoveries, world famous for 40 years, were proved fraudulent in 1953. A few implements have been found in the raised beaches, especially at Slindon, and in the river gravels near Pulborough. The Mesolithic food-gatherers left a scatter of remains along the sand ridges of the Weald and on Tertiary deposits near Peacehaven. Primitive agricultural communities from the Neolithic to the Roman period preferred the chalk, though they hunted in the Weald. Four of the rare Neolithic "causewayed camps" lie on the Downs, the two larger ones being at Whitehawk (Brighton racecourse) and the Trundle (inner ring) at Goodwood. There is also a group of flint-mining sites near Worthing, including the well-known Cissbury and Harrow Hill flint mines. The Early and Middle Bronze Ages are poorly represented but include bell barrows on Bow Hill and on Monkton Down, Treyford,

as well as the vanished Hove Barrow, which yielded a magnificent amber cup and other objects. Remains of the Late Bronze Age are abundant, including several examples of the earliest identifiable farm sites with their field systems, notably at Plumpton Plain near Brighton, New Barn Down near Worthing, and Itford Hill near Lewes. Many bronze implements have been found, singly and in hoards, as well as gold ornaments, including the lost Mountfield treasure near Battle. The Iron Age is notable for the hill forts on the Downs, especially the Trundle (outer ring) at Goodwood, Cissbury near Worthing, and the Caburn near Lewes. The first two were constructed perhaps in the 3rd century B.C. and abandoned before the Roman occupation; the Caburn was rather later and appears to have been captured by the Romans soon after A.D. 43. Farm sites of the Iron Age have been found on Park Brow near Cissbury and elsewhere, and many gold coins of the Belgic kings of the Commius dynasty have been found at Selsey.

(Et. C. C.)

History.—About the beginning of the Christian era a dynasty of British chieftains was established in the peninsula of Selsey. When the Romans invaded Britain in A.D. 43, the last of these chiefs, Cogidumnus, proved so useful an ally that he was made *legatus,* or official administrator, and given an extended kingdom (*regnum*). His centre, Noviomagus (Chichester), was developed as a tribal capital by the Romans, who made a great road (Stane Street) to London and others to Calleva (Silchester) and Venta Belgarum (Winchester), and minor roads connecting the downland corn districts and the Wealden iron mines with London. The fertile coast and downland area west of the Pevensey lagoons was developed with many villas or large farms. During the 3rd and 4th centuries fortresses were built for defense against pirates, one being at Anderida (Pevensey, where half the 20-ft. [6 m.] high walls still stand). After the Roman troops left Britain, about 410, civilization decayed, and in 477 a band of Saxons under Aella (Ella) and his three sons landed near Selsey and occupied the country, slowly fighting their way eastward until in 491 they stormed the last stronghold of Andredesceaster—usually assumed to be Pevensey—and massacred its defenders. The South Saxon conquest seems to have been ruthless and complete: no Celtic place-names survived, except those of three rivers—Tarrant (later Arun), Lavant, and Limene (later Rother). Aella's son Cissa probably occupied the walled Roman city called Chichester after him; but Sussex, the land of the South Saxons, soon fell under the control of Wessex, except for a (probably later) settlement in the east near Hastings, which seems to have retained some independence until 1011, when the Danes are said to have overrun it and the rest of Sussex.

In 681 Aethelwalh, one of the semi-independent kings, received the exiled Bishop Wilfrid, gave him large estates, and encouraged or ordered his subjects to accept Christianity. Wilfrid established a monastic bishopric at Selsey, and during the next two centuries churches were built and endowed throughout the county. Estates on the coast of Sussex were granted to Norman monasteries, notably to the abbey of Fécamp. In 1066, when Harold II was elected king, William I landed at Pevensey and marched to Hastings, near which town the decisive Battle of Hastings was fought on Oct. 14. On the site William built his votive Battle Abbey. Probably in order to secure his communications between Normandy and London, William divided Sussex into five blocks, each running from the coast, with a port, to the northern bounds of the county. Each of these districts, known as rapes, *i.e.,* districts that were "roped off," was in the hands of a trusted Norman lord, whose castles were built at Hastings, Pevensey, Lewes, Bramber, and Arundel. Later, about 1250, a sixth rape, Chichester, was separated for administrative purposes from Arundel. In the Domesday Book of 1086 the liberty of the abbot of Battle is also called a rape, but in all other records it is called the lowy. The boundaries of the rapes ran roughly parallel from north to south, and each rape contained a river, a castle, and a forest. From Domesday it is clear that the northern boundary of Sussex was still uncertain and that scarcely any villages existed in the wooded districts of the Weald, though many areas there were attached to manors in the settled south, serving at first as pastures for swine but being gradually cleared and settled. In 1086 the chief towns were Chichester, to which city the cathedral see had been moved from Selsey in 1075, and Lewes, which as early as 930 had been one of the few boroughs in England to be allowed two mints. Of Hastings, then an important harbour and one of the Cinque Ports (*q.v.*), no details are given. The Norman Conquest brought much building of churches and the foundation of the great Cluniac priory of Lewes and of "alien priories" (cells of Norman abbeys) at Boxgrove, Sele, and Wilmington.

During the reign of Henry III the see of Chichester was occupied by Bishop Richard de Wyche, whose saintly character led to his canonization in 1262, the shrine of St. Richard in the cathedral becoming a centre of pilgrimage. Although the castles of Sussex were held by supporters of King Henry III, it was on the Downs above Lewes that the royal forces were decisively defeated by Simon de Montfort in 1264; but Pevensey Castle held out until the king was restored to power. About this time a series of storms damaged the Cinque Port of Hastings and threatened to destroy the "ancient town" of Winchelsea. Accordingly, Edward I removed the inhabitants of Winchelsea to a safer site, where he laid out a town on a plan of rectangular blocks. The coast, however, soon suffered other assaults, the Hundred Years' War bringing constant raids by the French, who burned Hastings, Rye, and Winchelsea. The plague known as the Black Death hit the county heavily in 1349, killing about a third of the population, and there were further outbreaks in 1361 and 1366. Distress and misgovernment led the men of Sussex to support the Peasants' Revolt in 1381 and to take a prominent part in Jack Cade's Rebellion in 1450.

The Tudor period brought increased prosperity, but its importance in Sussex lies mainly in the realm of religion. On the whole, Sussex accepted the Protestant reform, so much so that during the short reign of Mary I, 30 men and women were burned, at Lewes and elsewhere, as heretics. The memory of these martyrs gave a strongly antipapal, and later puritan, tinge to popular feeling, though there were pockets of Roman Catholicism in the county. The county was therefore predominantly on the side of the Parliament during the Civil War, though Arundel Castle and the city of Chichester were for a time held for the king, and it was from Brighton that Charles II escaped to France after his defeat at Worcester. Puritan tendencies in the diocese are shown by the resignation or expulsion of more than 60 incumbents under the Act of Uniformity in 1662 and by the growth of the Quakers in spite of persecution.

During the last quarter of the 18th century, troubles with France led to the formation of local volunteers, and the movement was speeded up by the French Revolution, many of whose victims sought shelter in the Sussex coastal towns. A great camp was established in 1793 on the Downs near Brighton, and others near Eastbourne and Bexhill; when Napoleon I threatened invasion the coast was fortified by a chain of Martello towers, of which the westernmost was at Seaford. Brighton had since 1750 been developing into a fashionable watering place, especially from the first visit (1783) of the Prince Regent (afterward George IV) and the building of the Royal Pavilion. With the cult of sea bathing other towns developed at Bognor (*see* Bognor Regis), Hastings (*q.v.*), and St. Leonards, Eastbourne (*q.v.*), and Worthing (*q.v.*).

The growth of coastal resorts, the urbanization of almost the whole coast, and the conversion of much of it into "dormitory towns" for London were the main features of the history of Sussex after the beginning of the 19th century.

Architecture.—Of monastic remains the chief are those of Battle Abbey, with its splendid gatehouse, Bayham Abbey, and Lewes Priory. Extensive remains of Robertsbridge Abbey and of the Augustinian priories of Michelham and Shulbrede and the alien priory of Wilmington are incorporated in modern houses. The friary chapels of Chichester, Winchelsea, and Rye are important, as is the medieval hospital of St. Mary at Chichester. Sussex is rich in churches built before or shortly after the Norman Conquest, such as Bosham, Sompting, and Worth. There are many mural paintings; an early group arose under the influence of Lewes Priory.

Pevensey Castle, built within the impressive walls of a Roman

fortress, has an early Norman keep but was mostly built about 1250. At Lewes the early keep and later barbican are noteworthy; at Arundel only the keep is ancient, and Hastings and Bramber are mere fragments. Amberley Castle dates from 1377 and the lovely moated castle of Bodiam from 1386. Herstmonceux Castle (now occupied by the Royal Observatory), a brick building begun in 1444, was rather a defensible great house than a true castle, in this resembling the ruined early Tudor house of Cowdray. Of later great houses, Parham, Petworth, and Up Park (the last two belonging to the National Trust) are outstanding. But it is in its wealth of minor houses that Sussex is particularly strong. The medieval examples are mostly timber framed; later building is mainly in brick, *e.g.*, at Chichester and Lewes; and the good tradition, come down through the charming Regency buildings of Brighton, was revived in the planning of many council estates. (*See* also ARUNDEL; BATTLE; BEXHILL; BRIGHTON; CHICHESTER; HASTINGS; HERSTMONCEUX; LEWES; PETWORTH; PEVENSEY; RYE; SEAFORD; SHOREHAM-BY-SEA; WINCHELSEA.)

Population and Administration.—At the first census in 1801 the population was, in round figures, 159,500; in 1851, 337,000; in 1901, 605,000; in 1951, 937,339; and in 1961, 1,077,517 (East Sussex 665,904, West Sussex 411,613). The respective figures for Brighton were: 7,300; 65,500; 102,300; 156,486; 163,159; and for Hove: 100; 4,100; 29,700; 69,535; and 72,973, showing the progressive urbanization of the county. In East Sussex are three county boroughs: Brighton, Eastbourne (1961, 60,918), Hastings (66,478); four municipal boroughs: Bexhill (28,941), Hove, Lewes (13,645), Rye (4,438); and six urban and five rural districts. West Sussex has three municipal boroughs: Arundel (2,617), Chichester (20,124), Worthing (80,329), and five urban and six rural districts. Crawley (*q.v.*) New Town, designated in 1946, had a population of 54,047 in 1961.

The formation of the two administrative counties of East and West Sussex in 1889 regularized a division that is traceable in Saxon times, corresponding to the two archdeaconries of Lewes and Chichester. The creation of five rapes, each originally with its own sheriff in addition to the king's sheriff of the whole county, obscured this division, but a long struggle over whether the County Court should be held at Chichester or Lewes was compromised in 1504 by an order for alternate sessions. From the reign of Elizabeth I, Quarter Sessions records were kept separately for East and West Sussex, with one joint session yearly. After the grant of the honour of Pevensey to John of Gaunt in 1372, this district became part of the duchy of Lancaster; the privileges of the manor of Bosham and of the Cinque Ports, the ecclesiastical lowy of Battle Abbey, and the peculiars of the archbishop of Canterbury complicated the medieval jurisdiction of the county.

From 1295, members of Parliament were returned more or less regularly by the city of Chichester and the boroughs of Arundel, Bramber, East Grinstead, Horsham, Lewes, Midhurst, Shoreham-by-Sea, and Steyning, and the Cinque Ports of Hastings, Rye, Seaford, and Winchelsea. Many of these constituencies were small and very corrupt, and under the Reform Act of 1832 five lost both members and four lost one, but Brighton was assigned two members. There are four county and four borough constituencies in East Sussex. West Sussex returns four members to Parliament. Brighton returns two members, Eastbourne one, and Hastings one. The University of Sussex was founded at Brighton in 1961, with its headquarters in the 18th-century Stanmer House.

The Economy.—Sussex is still heavily wooded; in early times the Weald was tree covered, the clay producing oaks and the lighter soils favouring beech. The small fields there became good corn-growing areas, after improved drainage was provided. Most arable land, however, has always lain on chalk and greensand and along the coastal plain. This last, especially near Worthing, became a centre of market gardening. Hops are grown in the east, though less widely than formerly. Under John Ellman of Glynde between 1780 and 1830 the breed of Southdown sheep became famous, but since 1870 sheep have almost vanished from the Downs. Cattle have increased, particularly for dairy herds, and the rearing and fattening of poultry is also an active industry. Nor is the harvest of the sea negligible, though less important than in medieval times, when Winchelsea was famous for plaice, Arundel for mullet, and Selsey for cockles, and the Cinque Ports were as much concerned with herring as with naval transport and piracy.

The sea was once the source of the salt industry; a quarter of all salt pans recorded in Domesday Book were in Sussex. Salt boiling depended on fuel, and the Sussex woods supplied fuel also for glassworks round Kirdford and Wisborough Green from the 13th to the 17th century, as well as for pottery, tile, and, later, brick kilns. Sussex oak was in demand for naval and other shipbuilding. The plentiful supply of fuel and iron ore made the county a centre of the iron industry from Roman times until the end of the 18th century. From Tudor times Sussex cast-iron ordnance, as well as domestic objects, were in demand; but when it became possible to use pit coal for smelting, the industry moved north to the coalfields.

Although the Weald was not impenetrable, Sussex roads were notoriously bad, and in winter often impassable, until the coming of turnpike roads toward the end of the 18th century. A railway from London to Brighton was opened in 1841, and the county is now served by the Southern Region of British Railways. A regular cross-channel service to Dieppe is maintained from Newhaven.

Kingley Vale and Lullington Heath are nature reserves; 10,618 ac. (4,297 ha.) of Sussex were owned by the National Trust in 1963 and 1,414 ac. (572 ha.) protected; 15 areas belonged to the Forestry Commission.

SUSSEX, KINGDOM OF (*Súð Seaxe; i.e.*, the South Saxons), one of the kingdoms of Anglo-Saxon Britain, the boundaries of which coincided in general with those of the modern county of Sussex. According to the tradition given in the Anglo-Saxon Chronicle, it was in 477 that a certain Ella (Aella) led the invaders ashore at a place called Cymenes ora and defeated the inhabitants. A further battle at a place called Mearcredesburne is recorded for 485, and in the annal for 491 we read that Ella and Cissa his son sacked Anderida (Pevensey) and slew the inhabitants. Ella is the first king of the invading race whom Bede describes as exercising supremacy over the southern English.

The history of Sussex now becomes a blank until 607 when Ceolwulf of Wessex is found fighting against the South Saxons. In 681 Bishop Wilfrid of York, on his expulsion from Northumbria by Ecgfrith, retired into Sussex, where he remained until 686 converting its pagan inhabitants. According to Bede, Aethelwalh, king of Sussex, had been previously baptized in Mercia at the suggestion of Wulfhere, who presented him with the Isle of Wight and the district about the river Meon in Hampshire. After Wilfrid's exertions in relieving a famine which occurred in Sussex the king granted to him 87 hides in and near the peninsula of Selsey which, with a lapse until 709 after Wilfrid's retirement, remained the seat of the South Saxon bishopric until the Norman Conquest. Shortly afterward, however, Aethelwalh was slain and his kingdom ravaged by the exiled West Saxon prince Ceadwalla. The latter was eventually expelled by two princes Berhthun and Andhun, who assumed the government of the kingdom. In 686 South Saxons attacked Hlothhere, king of Kent, in support of his nephew Eadric, but soon afterward Berhthun was killed and the kingdom subjugated for a time by Ceadwalla, who had now become king of Wessex.

Of the later South Saxon kings we have little knowledge. In 692 a grant is made by a king called Nothelm to his sister, which is witnessed by two other kings called Nunna and "Uuattus." Nunna is probably to be identified with Nun, described in the Chronicle as the kinsman of Ine of Wessex who fought with him against Gerent, king of the West Welsh, in 710. According to Bede, Sussex was subject to Ine for many years. A grant, dated by Birch about 725, is made by Nunna to Eadberht, bishop of Selsey, and to this too "Uuattus" appears as a witness. In 722 we find Ine of Wessex at war with the South Saxons, apparently because they were supporting a certain Aldbryht, probably an exile from Wessex. An undated grant is made by Nunna about this time, which is witnessed by a King Aethelberht. After this we hear nothing more until shortly before 765, when a grant of land is made by a king named Aldwulf with two other kings, Aelfwald

and Oslac, as witnesses. In 765 and 770 grants are made by a King Osmund, the latter of which is witnessed by Offa of Mercia. Offa also appears as witness to two charters of an Aethelberht, king of the South Saxons, and in 772 he grants land himself in Sussex, with Oswald, *dux* of the South Saxons, as a witness. It is probable that about this time Offa definitely annexed the kingdom of Sussex, as several persons, Osmund, Aelfwald and Oslac, who had previously used the royal title, now sign with that of *dux*. In 825 the South Saxons submitted to Ecgberht, and from this time they remained subject to the West Saxon dynasty.

Birch, *Cartularium Saxonicum* (London, 1885–93); F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (Oxford, 1947); R. H. Hodgkin, *History of the Anglo-Saxons*, 2 vol., 3rd ed. (Oxford, 1953).

SUSU, a tall and slender Negro people of western Africa, about 238,000 of whom dwell in Guinea and 50,000 in the northwestern districts of Sierra Leone. They live in confederate villages under paramount chiefs. Each individual belongs to a patrilineal clan, many of which have names common to the Mande-speaking peoples of this region. Within the village, the houses of particular lineages are grouped together. Marriage between cross-cousins is favoured. Polygynous unions are common and a man inherits his deceased brother's wives. Traditionally, the Susu were animists and had politico-religious confraternities known as *Simo*, but they have now largely adopted the Muslim faith, and, influenced by new economic forces, their way of life is changing.

Susu is also the name of the fresh-water dolphin of the Ganges; it is blind, fish-eating and pale in colour (*see* WHALE).

SUTHERLAND, EARLS AND DUKES OF. The first earl of Sutherland is generally taken to be a certain William (d. *c.* 1248), whose father, Hugh Freskin (d. *c.* 1214–22), acquired the district of Sutherland about 1197. Probably about 1235 William was created earl of Sutherland. His descendant William, the 5th earl (d. 1370), was a person of some importance in the history of Scotland; he married Margaret (d. *c.* 1346), daughter of King Robert Bruce. His descendant John, the 9th earl, died unmarried in 1514.

John's sister and heir, Elizabeth (d. 1535), countess of Sutherland in her own right, married Adam Gordon (d. 1538), a younger son of George Gordon, and earl of Huntly, and a grandson of King James I, and before 1516 Gordon became earl of Sutherland by right of his wife. He was succeeded by his grandson John (1525–67), who was poisoned at the instigation of George Sinclair, 4th earl of Caithness. His great-grandson John, the 5th earl of the Gordon line (1609–1679), was a strong Covenanter, being called by his associates "the good Earl John"; he fought against Montrose at Auldearn in 1645, but afterward he rendered good service to Charles II. John Gordon (1661–1733), who became the seventh earl in 1703, supported the revolution of 1688 and was a commissioner for the union of England and Scotland. He was a Scottish representative peer in four parliaments, president of the board of trade and manufactures, and lord lieutenant of the eight northern counties of Scotland. He was active in putting down the rising of 1715. This earl, who took the name of Sutherland instead of that of Gordon, was succeeded by his grandson William (1708–50), a representative peer, who helped to suppress the rebellion of 1745. William, the next earl, died without male issue in 1766, his daughter Elizabeth (1765–1839) claiming the peerage. Her title thereto was confirmed by the house of lords in 1771.

Established in the possession of the title and estates of the earldom, the countess of Sutherland was married in 1785 to George Granville Leveson-Gower (1758–1833), who succeeded his father as 2nd marquess of Stafford in 1803. In addition to the estates of the marquessate of Stafford, Leveson-Gower inherited the Bridgewater canal and estates from his maternal uncle, Francis Egerton, 2nd duke of Bridgewater, and these properties, together with his wife's estates, which included almost the whole of the county of Sutherland, made him a "leviathan of wealth," as he is called by Charles Greville. In 1833 he was created duke of Sutherland. Leveson-Gower was a member of parliament from 1778 to 1784, and again from 1787 to 1799 when he was called to the house of lords as Baron Gower. He was British ambassador in Paris from 1790 to 1792. From 1799 to 1801 he was joint postmaster general. He was a collector of paintings, and purchased Stafford house, London. He was responsible for the construction of about 450 mi. of road and of many bridges, but his policy of removing a large number of his tenants from the interior to the coast aroused bitterness and criticism. However, he reduced rents and brought thousands of acres into cultivation. He died at Dunrobin castle on July 5, 1833.

See G. E. C(okayne), *Complete Peerage*, vol. x (London, 1952); Sir Robert Gordon and George Gordon, *Genealogical History of the Earldom of Sutherland . . . to 1651* (Edinburgh, 1813); and also STAFFORD; BUCKINGHAM, EARLS, MARQUESSES AND DUKES OF.

SUTHERLAND, GEORGE (1862–1942), U.S. supreme court justice from 1922 to 1938, and often spokesman for the court when it nullified social legislation, was born in Buckinghamshire, Eng., on March 25, 1862. Brought to Utah soon after he was born, Sutherland attended Brigham Young university and the University of Michigan law school. He was admitted to the bar in 1883. Subsequently he settled in Salt Lake City and became active as a Republican in Utah politics, becoming in 1896 a member of the state senate. He was widely supported by members of the Church of Jesus Christ of the Latter-day Saints (Mormons) although he himself was not of their number. From 1901 to 1903 he was a member of the U.S. house of representatives and from 1905 to 1917 he served in the U.S. senate, his principal legislative accomplishment being the impetus he gave to the 19th (woman suffrage) amendment to the U.S. constitution. He was an ardent exponent of workmen's compensation and legislation for the benefit of seamen. In the 1920 presidential campaign and thereafter until his appointment to the court in 1922, he was an intimate adviser of Pres. Warren G. Harding. On the court, Sutherland quickly became identified with the conservative majority, writing the opinion outlawing the minimum wage (*Adkins* v. *Children's Hospital* 261 U.S. 525) (1923). Paradoxically, despite his hostility to governmental action, his most enduring contribution is probably his conception of the foreign relations power. It was, he successfully argued, not subject to the usual constitutional limitations (*U.S.* v. *Curtiss-Wright Export Corp.*, 299 U.S. 304 [1936]). He retired from the supreme court on Jan. 5, 1938, and died on July 18, 1942, in Stockbridge, Mass.

See J. F. Paschal, *Mr. Justice Sutherland* (1951). (J. F. PL.)

SUTHERLANDSHIRE, a county of northern Scotland, bounded north and west by the Atlantic ocean, east by Caithness, southeast by the North sea and south by the shire of Ross and Cromarty; pop. (1961) 13,442. The land area is 2,028 sq.mi. The western and northern shores are indented with beautiful bays and sea lochs, and terminate at many points in precipices and rugged headlands. Almost the whole county is mountainous; the summits are often of finer outline than those of the Grampians to the south, and the surface generally consists of desolate moorland. The highest point is Ben More in Assynt (3,273 ft.).

An irregular line from Loch Eriboll on the north coast to the neighbourhood of Cromalt near the southern boundary separates the two rock groups that form the foundation of the major portion of the county. On the western side of this line are ancient gneisses and schists (the Lewisian gneiss); these are penetrated by innumerable basic and acid dikes which generally have a northwest to southeast trend. On the eastern side of the line, occupying the whole of the remaining area except the eastern fringe of the county, is a younger series of metamorphic rocks, the Moine schists. In the northwest Torridonian breccias and sandstones rest unconformably on this gneiss, and Cambrian rocks upon the Torridonian; the white Cambrian quartzite capping the dark Torridonian rocks on some of the hills forms a striking scenic feature. Granite masses appear in the eastern schists, and patches of Old Red Sandstone form high land near the southeast coast. Evidence of glacial action is widespread.

The chief river is the Oykell, which, rising in Coniveall or Conival (3,234 ft.), a peak of Ben More, flows south and then south-

east for 25 mi. to Dornoch firth. Other rivers flowing to Dornoch firth are the Helmsdale (20 mi.), the Brora (26 mi.), preserving in its name (bridge river) the fact that its bridge was once the only important one in the county; and the Fleet (17 mi.), the estuary of which was embanked for 1,000 yd., in 1813 by Thomas Telford, whereby rich alluvial land was reclaimed. The Halladale (22 mi.), rising in Knockfin on the borders of Caithness enters the sea to the east of Portskerra. The district of Assynt is honeycombed with lakes and tarns, but the only large lake is Loch Assynt, 6¼ mi. long, 215 ft. above the sea. There are many waterfalls; those of Escallin, near the head of Glencoul, are among the finest in Great Britain.

Of the prehistoric inhabitants, there are considerable remains in the form of many *brochs* (or round towers) "Picts' houses," mounds, cairns and hut circles. Dun Dornadilla, in the parish of Durness, 4 mi. S. of Loch Hope is a tower, 150 ft. in circumference, still in good preservation, and 10 mi. N.W. of the angling resort of Altnaharra.

The Norse jarl Thorfinn overran this part of Scotland in 1034 and the Scandinavian colonists called it, in relation to their settlements in the Orkneys and Shetlands, *Sudrland* ("southern land"). After the conquest of the district by the Scottish kings, an area called Sutherland and including part of the modern county was conferred on Hugh Freskin (a descendant of Freskin of Moray), whose son William was created earl of Sutherland probably about 1235. On the southern shore of Helmsdale creek stand the ruins of the castle in which the 11th earl and his wife were poisoned by his uncle's widow in 1567, with a view to securing the title for her only child, who was next of kin to the earl and his son. Ardvreck castle, now in ruins, near Inchnadamph on the northern side of Loch Assynt, was the prison of the marquess of Montrose after his defeat at Invercarron (1650), from which he was taken by Neil Macleod of Assynt for execution at Edinburgh. In the graveyard of the old church of Durness is a monument to Robert Mackay, called Rob Donn (the brown), the Gaelic poet (1714–78).

Only about 1½% of the total area was arable land in 1938, the shire ranking lowest in Scotland in this respect. The great mass of the surface is grazing ground and deer forest. The best land adjoins Dornoch firth, where farming is in an advanced condition and there are fertile patches along the river valleys. At the beginning of the 19th century the first duke of Sutherland (then marquess of Stafford) adopted a policy of wholesale clearance of the crowded crofters of the interior to the coast. The duke incurred great obloquy, but persisted in his policy, which included reduction of rent, reclamation of land, and abolition of the tacksman or middleman. He also did much to open up the shire generally by the construction of roads and bridges. Attempts were made to repeople some of the glens (Strathnaver, for example) depopulated by the clearances. Crofters still largely predominate; over half the 2,196 holdings in 1955 were 5 ac. or under. The average size, 13 ac., is the smallest in Scotland, excepting the Shetland Islands. Oats, turnips and swedes, and potatoes are grown. The raising of sheep, mostly Cheviot, is the staple business of the county, and cattle are also kept. Deer forests belonging to the duke of Sutherland cover a large area. Next to agriculture, the deep-sea fisheries and the salmon fisheries in the rivers are the most important industries. Helmsdale and Golspie are fishing villages and fishing ports have been established at Loch Clash, Kinlochbervie, and at Culag, Lochinver, both on the west coast. Herrings are the principal catch, but cod, ling and other fishes are also taken. At Brora whisky is distilled, some woolens are manufactured, coal is mined and bricks are made. The exceptional facilities offered by the deer forests, moors and the many lochs and rivers attract large numbers of sportsmen; and Dornoch, Lochinver, Golspie and Brora are well known as holiday towns.

The railway enters the county at Invershin, goes to Lairg, Brora, Helmsdale, Kildonan and Forsinard, after which it leaves the shire. Glasgow steamers call at Lochinver about every ten days.

The population was 13,442 at the time of the 1961 census; the population in 1921 was 17,802. Gaelic and English were spoken by 3,286 persons in 1951. The county is the least densely populated in Scotland. Several islands lie off the west and north coast, but they are uninhabited. Dornoch (pop., 1951, 793), the county town, is the only royal burgh and small burgh. There are six county districts. The shire returns one member to parliament with Caithness, and forms a joint sheriffdom with Ross and Cromarty, with a sheriff-substitute resident at Dornoch.

SUTLEJ (*Zarados* of Ptolemy and Arrian; Vedic *Sutudri* or *Satadru*) one of the "five rivers" of the Punjab. It rises near the westernmost Manasarowar lake in Tibet, threads its way through the Himalayan gorges, crosses Himachal Pradesh, India, and enters Hoshiarpur district. Thence, it flows through the plains of the Punjab, receiving the Beas in the southwest of Kapurthala district and forming for 65 mi. the Indo-Pakistan frontier; it joins the Chenab, 40 mi. W. of Bahawalpur, Pakistan, after a 900-mi. course. The two rivers there form the Panjnad.

As the river flows through an area of precarious rainfall, dams have been built all along it: works include the Bhakra-Nangal multipurpose project; the Sirhind canal; and the Sutlej valley project. Of the five rivers it has the largest catchment area (18,500 sq.mi.) but in relation to its size it has the poorest discharge.

SUTO (Basuto), the occupants of Basutoland and neighbouring areas in South Africa. They are not all of one ethnic stock but consist of those who accept the authority of the paramount chief or king of Basutoland. The Basuto nation was created by the chief Moshoeshoe (known to Europeans as Moshesh) in the 19th century (*see* Basutoland: *History*). The majority are of southern Sotho linguistic stock, with a small minority from the Nguni-speaking tribes (about 15%). By the early 1960s they numbered about 500,000, though about 45% of the adult males were absent from the country as labour migrants.

The people live in small hamlets, which are grouped into parishes under hereditary headmen possessing administrative and judicial powers. Parishes are grouped into chiefdoms with hereditary chiefs, and these form provinces under chiefs, most of whom are close kin of the paramount. Authority at all levels is held by the genealogically senior man of the patrilineal line of descent that is regarded as the founding line of the settlement or chiefdom, the members of which regard their chief as a senior kinsman rather than as a mere administrative official.

The paramount is the senior patrilineal descendant from Mamohate, the senior wife of Moshoeshoe. He is advised both by a council of his close kin and by the national assembly, the *pitso*. He acts as head of the nation in all affairs, as final court of appeal and as ritual guardian of the country.

Corn (maize) is the staple food of the people; sorghum in the lowlands and wheat in the mountain areas are also important crops.

Initiation and formal instruction at puberty are practised, but the Basuto have no age-set system. Marriage is by transfer of bridewealth and preferred marriage is with a cross cousin, although marriage with a parallel cousin is also permitted.

Most Basuto have become Christian. The central feature of the pagan religion was the cult of the ancestors, who were worshiped by their descendants. Today, pagans believe in a Supreme Being, but this is probably a belief taken from Christian missionaries. *See* also Africa: *Ethnography (Anthropology)*: *Southern Africa;* Basutoland: *The People.*

SUTTEE, the Indian practice of concremation of a widow on the pyre of her deceased husband (Sanskrit *satī*, "true" wife). Whether the usage existed in Vedic India has been hotly debated. World-wide primitive usage compelled a widow to be the wife of her husband's brother or near kinsman, or, if he had been of princely standing, to be immolated with his concubines, slaves, steeds, etc., at his tomb, to maintain his dignity in the next world. This usage eventually found priestly support in the Hindu conception of matrimony as a bond eternally renewed when the married pair were reborn in succeeding lives—a concept hard to reconcile with polygyny. In late Hindu myth Sati was Siva's spouse who, resenting a slight put upon her lord by her father, destroyed herself but was reincarnated as Uma, the beauteous

wife of Siva. Here Sati's act is prompted by a very different motive, and the tale supports the view that the text of the *Rig-Veda* was tampered with, to support the Brahmanical ideal.

From early times reformers denounced the usage, and even the Brahmanical jurists sometimes deprecated suttee, allowing the widow the option of living an ascetic life. The Jains do not practice suttee. Buddhism probably discouraged it. Sikhism expressly forbade it, yet on Ranjit Singh's death, in 1839, several of his widows were burned. Outside British jurisdiction, suttee continued in families of high rank until late in the 19th century.

SUTTER, JOHN AUGUSTUS (1803–1880), U.S. pioneer on whose land the first great California gold discovery was made in 1848. Born of Swiss parents at Kandern, in the grand duchy of Baden, on Feb. 15, 1803, he moved to the U.S. in 1834 and bought land in Missouri. In 1839 he went to California, where he was given 49,000 ac. (19,830 ha.) of land on the Sacramento River by the Mexican governor and was appointed "Commissioner of Justice and Representative of the Mexican Government on the Frontier of the Rio del Sacramento." He built a fort, mill, tannery, distillery, blanket factory, smithy, and other shops. He imported Hawaiians and hired Indians to cultivate the land. He traded for furs, purchased boats that plied the Sacramento, acquired more land, and soon became wealthy. His settlement, "New Helvetia," became a rendezvous for adventurers, sailors, trappers, and hunters, including an increasing number of Americans. In 1846 when the Bear Flag revolt took place, Sutter at first maintained an appearance of fidelity to the Mexican government but made little objection when John C. Frémont's forces took control of his fort. After California was acquired by the U.S., Sutter felt the need of a new mill. It was while the millrace was being dug that an employee made the famous gold discovery on Jan. 24, 1848. Sutter tried to keep the strike a secret, but his property was soon overrun by gold seekers. Worse, the U.S. Supreme Court found the title to 98,000 ac. of his land invalid. Much of what was left him was used to reimburse those to whom he had granted subtitles, which he was forced to make good. Soon he was bankrupt. From 1871 he petitioned Congress for reimbursement. He died at Washington, D.C., on June 18, 1880, the evening after Congress had again adjourned without recognition of his claims.

SUTTNER, BERTHA FÉLICIE SOPHIE, Baroness von (1843–1914), Austrian novelist and pacifist, who won the Nobel Prize for Peace in 1905, was born at Prague on July 9, 1843, the daughter of Count Franz von Kinsky, Austrian field marshal. In 1876 she was hired as a secretary-housekeeper by Alfred Nobel, the munitions maker, but soon married Baron Arthur Gundaccar von Suttner, whose family disapproved of the match because she was seven years his senior and of a poor family. The couple lived at Tiflis in the Caucasus until 1885, when the Von Suttner family was reconciled to the marriage. Though she saw Nobel only twice more, she corresponded with him and is credited with influencing him in the establishment of the Nobel Prize for Peace.

Of her novels, *Die Waffen nieder!* (1889; best Eng. trans. by T. Holmes, *Lay Down Your Arms!*, 1892) was second in popularity in the 19th century only to Harriet Beecher Stowe's *Uncle Tom's Cabin*. *Das Maschinenzeitalter* (1899) reflects the scientific and free-thinking basis of her pacifism as derived from H. T. Buckle, Spencer, and Darwin. She founded the Austrian Society of Peace-Lovers in 1891 and edited the international pacifist journal *Die Waffen nieder!* from 1892 to 1899. She died in Vienna on June 21, 1914.

See Ellen Key, *Florence Nightingale and Baroness von Suttner* (1919).

SUTTON, one of the 32 London boroughs that came into existence on April 1, 1965, under the provisions of the London Government Act 1963, which reorganized local government in the metropolis and the area around it. These 32 boroughs constitute Greater London (*see* London). Sutton, in the south, is composed of areas that were previously in Surrey: the former municipal boroughs of Beddington and Wallington and Sutton and Cheam, and the urban district of Carshalton. *See* Beddington and Wallington; Carshalton; Sutton and Cheam.

SUTTON AND CHEAM, a municipal borough (1934) of Surrey, Eng., which under the London Government Act 1963 was amalgamated on April 1, 1965, with Beddington and Wallington, and Carshalton to form the new London borough of Sutton (*q.v.; see* also London). Sutton and Cheam Municipal Borough was a residential area on the northern edge of Banstead Downs, 11 mi. SSW of Charing Cross. Pop. (1961) 79,008. Area 6.8 sq.mi. It was a parliamentary constituency. In Cheam are many old wooden houses, including Whitehall (early Tudor) and the Old Cottage, a local museum. Cheam was divided by Archbishop Lanfranc into two manors. Henry VIII confiscated both and also Sutton Manor, which belonged to Chertsey Abbey.

SUTTON COLDFIELD, a municipal borough (1886) in the Sutton Coldfield Parliamentary Division of Warwickshire, Eng., 7 mi. NNE of Birmingham. Pop. (1961) 72,165. Area 21.8 sq.mi. It is a residential district with a few light industries, and the British Broadcasting Corporation's television transmitter mast (750 ft.) is a landmark. It was at Sutton Coldfield that John Wyatt, a native, invented a mechanical device in 1733 for spinning cotton. The parish church of Holy Trinity was built in the 14th century and contains the tomb of Bishop Vesey (d. 1555), a great benefactor of the town. The Vesey Memorial Gardens were laid out in 1938; his birthplace, Moor Hall, is a private house. Other old houses are New Hall at Walmley, the Moat House (Queen Anne) and the grove at Wishaw (14th century). Bishop Vesey's grammar school was founded in 1541 and the Roman Catholic seminary of Oscott College in 1785. Its first charter of incorporation (1528) gave the town the right to be described forever as the Royal Town of Sutton Coldfield and also gave 2,400 ac. (including 75 ac. of water) of Sutton Forest, now Sutton Park, to the town.

SUTTON HOO SHIP BURIAL, an early Anglo-Saxon king's grave containing a ship fully equipped for the afterlife (but no body), which came to light in 1939 with excavations at Sutton Hoo, an estate near Woodbridge, Suffolk, Eng. Richest Germanic burial found in Europe since the 17th century, it throws important light on the wealth and contacts of early Anglo-Saxon kings and is particularly valuable because burial of the dead in a ship is rare in England, although described in *Beowulf* (*q.v.*).

The ship's timbers had rotted away, but their impression in the sand and the rivets that remained showed it to be a mastless clinker-built rowboat more than 80 ft. long. The grave goods, laid out amidships, included a sword with a gold and garnet pommel, a gold-mounted shield, a visored helmet enriched with silver inlay, a mail coat, an iron-handled ax, three angons (throwing javelins), four spears, and a knife. Ceremonial objects, showing that the deceased was a king, were a wrought iron stand surmounted with a stag, which is explained as a unique Anglo-Saxon standard, and a great whetstone, 2 ft. long, carved with bearded faces.

The wealth of the obscure kingdom of East Anglia (*q.v.*) is shown by 41 items of solid gold, the fittings for a baldric, and ceremonial regalia. These include a magnificent purse lid decorated with seven ornamental plaques, and a pair of curved and hinged epaulettes whose ornamentation of interlaced beasts and checker patterns is reminiscent of Hiberno-Saxon manuscript art. Small buckles and strap mounts, buttons, and pyramid studs for the sword knot are all lavishly decorated with garnets, and there is an impressive gold buckle weighing more than 14 oz.

Besides the gold cloisonné jewelry, probably made in a single English workshop, there was a quantity of imported silverware. One great silver dish bears the control stamp of the emperor Anastasius I (491–518) and is the only demonstrably Byzantine object so far found in England. In addition, there are a fluted bowl, a set of nine shallow bowls, a plain silver bowl, a ladle cup, and two spoons, probably christening presents, inscribed in Greek with the names Paul and Saul. A bronze bowl of Near Eastern manufacture and six small vessels made from gourds show wide East Anglian trading connections. The skill of the Celtic west is represented by three hanging bowls ornamented with enameled escutcheons, and inside one of these was found the remains of a small rectangular harp, the earliest postclassical instrument known. Domestic objects included bronze cauldrons, ironbound buckets, drinking horns, a pottery bottle, and textiles.

There was no body or cremated remains in the grave, and it is

not certain whose cenotaph this was; its richness indicates a king, and Merovingian coins found in the grave date the deposit 650–670. In that period three kings of East Anglia died: Anna (d. *c.* 653), Aethelhere (d. 654), and Aethelwald (d. 662–663). A pagan burial, albeit with such Christian elements as the spoons, is, however, surprising for any of the kings, especially the latest. Anna was a notable Christian; his body was buried at Blythburgh, Suffolk, but the memorial could have been put up to placate some of his heathen followers. Aethelhere, however, seems the most likely candidate; he died fighting at the River Winwaed for Penda, the pagan king of Mercia, and his body was probably not recovered from the battle where Bede says many perished by drowning.

The rite of ship burial and certain items in the grave are most closely paralleled in Sweden and postulate a hitherto unsuspected Swedish origin for the East Anglian royal dynasty.

The grave goods are now in the British Museum.

SUTTON-IN-ASHFIELD, a market town and urban district in the Arkfield parliamentary division of Nottinghamshire, Eng., 12 mi. N.N.W. of Nottingham by road. Pop. (1961) 40,441. Area 16.4 sq.mi. The neighbourhood contains remains of Sherwood forest. Formerly the town relied solely on textiles but after the discovery of coal in the vicinity a variety of manufactures was introduced although its chief trade is still hosiery.

SU TUNG-P'O (regular name SU SHIH) (1036–1101) was one of China's greatest poets, painters and prose masters. He pioneered in the Sung school of Chinese painting. He excelled in dignified historical essays as well as in light, whimsical pieces. He was an authority in medicine who picked his own herbs, a great winebibber and maker of wines, a judge who sympathized with his prisoners, an inventor of such famous dishes as "Tung-p'o pork," an inkmaker, a renowned calligraphist whose every scribbled note was carefully preserved and whose family letters were inscribed in stone in his own lifetime. Wherever he was stationed as a magistrate, he dredged lakes, built canals, fought floods and constructed dams. He instituted hospitals and dispensaries, and was the first man to start the system of prison physicians because he could not stand the condition of the prisons. Alone, he fought the drowning of girl babies. He worked for famine relief and wrote successive letters to the empress dowager begging for forgiveness of tax to the poor. He forgave his friend who sent him to exile in Hainan Island, then almost outside the pale of civilization. All these actions made him indubitably the most loved and admired scholar of his and later days.

Of the eight prose masters of the T'ang and Sung dynasties, the Su family accounted for three, Tung-p'o himself, his brother Tse-yu and his father. When he went to the capital to take his examinations, Ou-yang Hsiu, the acknowledged leader of the scholars, said when he read his writings, "I must give place to this young man." His reputation was established. Later the court attendants reported that whenever they saw the emperor's chopsticks stop moving in the midst of eating, they knew it was a memorandum by Su Tung-p'o he was reading. It was his misfortune that the emperor listened to Wang An-shih, the social reformer, who banished all opposition to exile. Su Tung-p'o was first banished to Huangchow for four years (1080–84). There he took the poetic name of Tung-p'o, or Eastern Slope, the name of his farmstead; his regular personal name was Shih. The name Tung-p'o, with which he signed his famous paintings, became the one by which he was popularly known. With the emperor's death, during the Yuanyu regency of the empress dowager (1085–93), he was successively secretary to the emperor, governor of Chekiang, minister of civil service, of war, of education, and governor of Hopei. With the death of the empress dowager, the whole "Yuan-yu party" went again into exile (for seven years). Tung-p'o was banished to Huichow, in Kwangtung, and again to Hainan, whence he returned to China in 1101, one month before his death.

Tung-p'o's position and popularity came from a combination of literary brilliance and political integrity and his fearless championing of the people. His honesty with himself was the "bone" of his stature, while the charm of his personality, his wit, his gaiety and his literary accomplishments were the "skin and flesh" which gave to him the great charm which has endeared him to admirers throughout the generations.

See Lin Yutang, *The Gay Genius* (New York, London, 1947); *Selections from the Works of Su Tung-p'o,* trans. by C. D. LeGros Clark (London, 1931). (L. Y.)

SUVA, the capital, chief port and commercial centre, and largest town, of the British colony of Fiji (*q.v.*), near the mouth of the Rewa river on the southeast coast of Viti Levu, or "great Fiji," the principal island. First occupied by European settlers in 1870, it was selected for the new capital in 1877 although the actual move from Levuka on the island of Ovalau was delayed until 1882. From the original site on the western side of the Suva peninsula the town has spread to the north, west and south, while reclamation has provided space for the expansion of warehouses, factories, wharves and slipways. The rapidly increasing population reached 37,371 in 1956 and included 19,321 Indians, 9,758 Fijians, 3,394 Europeans, 2,094 part-Europeans and 1,647 Chinese.

Administration is by an elected municipal council. Secondary schools and a teachers' training college serve all ethnic groups. The central medical school provides medical and dental courses for native students from Pacific islands as far distant as New Guinea. Besides a general hospital there are special hospitals for mental and tuberculosis cases. Newspapers and periodicals are published in English, Hindustani and Fijian. Industry includes cigarette, soap and biscuit manufacture, copra-crushing and brewing. Electric power is generated locally. Shipping using the port ranges from tourist ships to small interisland vessels. Slipway facilities are widely used by vessels from surrounding island groups. A Royal New Zealand Air Force flying boat squadron is based at Lauthala bay. (R. M. FR.)

SUVÓROV, ALEXANDER VASILIEVICH, COUNT SUVÓROV RIMNIKSKY, PRINCE ITALYSKY (1729–1800), Russian field marshal, was born at Moscow on Nov. 24, 1729, the descendant of a Swede named Suvor who emigrated to Russia in 1622. He entered the army as a boy, served against the Swedes in Finland and against the Prussians during the Seven Years' War. After repeatedly distinguishing himself in battle he was made a colonel in 1762. He next served in Poland, dispersed the Polish forces under Pulawski, stormed Cracow (1768) and was made a major general. In his first campaigns against the Turks in 1773–74, and particularly in the battle of Kosludscki in the latter year, he laid the foundations of his reputation.

From 1787 to 1791 he was again fighting the Turks and won many victories; he was wounded at Kinburn (1787), took part in the siege of Ochakov, and in 1788 won two great victories at Focsani and on the Rimnik. For the latter victory, in which an Austrian corps under Prince Josias of Saxe-Coburg participated, Catherine II made him a count with the name Rimniksky in addition to his own name, and the emperor Joseph II created him a count of the Holy Roman empire.

On Dec. 22, 1790, Suvórov stormed Ismail in Bessarabia, and the sack and the massacre that followed the capture equals in horror such events as the "Spanish Fury" and the fall of Magdeburg. He was next placed at the head of the army which subdued the Poles, and repeated the triumph, and some of the cruelties, of Ismail at Warsaw. He was now made a field marshal, and was retained in Poland until 1795, when he returned to St. Petersburg.

His sovereign and friend Catherine II died in 1796, and her successor Paul dismissed the veteran in disgrace. But in February 1799 he was summoned by the tsar to take the field again, this time against the French Revolutionary armies in Italy.

The campaign (*see* FRENCH REVOLUTIONARY WARS) opened with a series of victories (Cassano, Trebbia, Novi) which reduced the French government to desperate straits and drove every French soldier from Italy, save for the handful under Moreau, which

maintained a foothold in the Maritime Alps and around Genoa. Suvórov himself was made a prince. But the later events of the eventful year went uniformly against the allies. Suvórov's lieutenant Korsákov was defeated by Masséna at Zürich, and the old field marshal, seeking to make his way over the Swiss passes to the Upper Rhine, had to retreat to the Vorarlberg, where the army, much shattered and almost destitute of horses and artillery, went into winter quarters.

Early in 1800 Suvórov returned to St. Petersburg in disgrace. Paul refused to give him an audience, and, worn out and ill, he died a few days afterward, on May 18, 1800. But within a year of his death the tsar Alexander I erected a statue to his memory in the Field of Mars, St. Petersburg.

Suvórov spared his own soldiers as little as he showed mercy to the population of a fallen city. He was a man of great simplicity of manners, and while on a campaign lived as a private soldier. But he had himself passed through all the gradations of military service. His gibes procured him many enemies. He had all the contempt of a man of ability and action for ignorant favourites and ornamental carpet-knights. Dragomirov (*q.v.*) avowed that his teaching was based on Suvórov's practice. Byron has given Suvórov a place in English literature in certain cantos of *Don Juan.*

SUWANNEE RIVER, the river of Stephen Foster's song "Old Folks at Home," rises in the Okefenokee swamp in southeast Georgia. As the river moves southward through Florida it is augmented by the discharge of many springs, and also receives the Withlacoochee, Alapaha and Santa Fe rivers. The channel is dredged 135 mi. inland from the Gulf to junction with the Withlacoochee; 250 mi. from its headwaters the Suwannee empties into the Gulf of Mexico, 22 mi. S. of Cross City, Fla. All but 35 mi. of the river's course is in Florida. In north Florida the Suwannee flows over shoals and boulders between high limestone banks lined with second-growth cedar. In its middle course it moves quietly through wild hammock and forested areas; in dry weather it forms only a narrow channel in a river bed of limestone strata which have been eroded into numerous curious forms. The banks of the river are heavily wooded with cypress and live oaks. Exotic flowers including gardenia, orchids and ixia are abundant. Bass, perch, catfish, bream and small game are plentiful.

In the 1780s the secluded bays and inlets of Suwannee sound were rendezvous points for pirates. Tales of buried treasure still persist. The Suwannee was the boundary between the Timucua and Apalachee Indian tribes when northern Florida was explored. They called it the Guasaca Esqui, meaning "River of Reeds." The present name is thought to be a Negro corruption of San Juanee, meaning "little St. John." (M. C. P.)

SUWARRO: *see* SAGUARO.

SUWAYDA', AS (Es SUWEIDA; SOUEIDA), town (administrative centre) and governorate (SUWEIDA) of the Jebel Druze (Jabal al Duruz) in the southern part of the Arab Republic of Syria. The town is 55 mi. S.S.E. of Damascus by road. Area (governorate): 2,143 sq.mi.; pop. (governorate, 1960) 99,512, (town, 1960) 18,121. The town, which stands on a hill on the site of a Roman settlement, is connected by road with Izra (Azra') and Damascus. The ancient name for the Jebel Druze was the Hauran. This area originally marked the boundary between Palestine and Syria. The northern part is known as El Lejja (the refuge), as robbers and rebels from the surrounding countries made it their hiding place. The volcanic nature of the soil makes it extremely fertile and wheat, barley, vetches and lentils are grown. Apples and grapes are marketed, but only locally because of poor communications.

The town, whose ancient name was Soada or Dionysias, is said to have been founded by the Nabataeans, but may date from an earlier period. The Nabataeans built a temple there to their god Dusares (later probably erroneously identified with Dionysus). The town came under Roman rule in the 1st century B.C. and Augustus handed it over to Herod the Great (reigned 40–4 B.C.). It remained in the possession of his family until A.D. 100. Herod Agrippa II encouraged the inhabitants to cultivate the soil and build houses. About 15 mi. S.S.W. of As Suwayda' is the ancient site of Bozrah (*q.v.*), a Roman colony under Alexander Severus. (M. V. S.-W.)

SUWON, a city in Kyŏnggi province, Republic of (South) Korea, about 26 mi. S. of Seoul on the Seoul-Pusan main railway. Population (1960) 90,806. Temperatures in the Suwon area range from an average of −5° C. (23° F.) in January to 27° C. (80° F.) in August. Average annual precipitation is about 46 in. Suwon's history as a town site goes back at least to the 5th century, though its present name dates from much later. In the 15th century Suwon was fortified as one of four bastions guarding the approaches to Seoul, and in 1794–96 new fortifications were constructed. Suwon was the provincial capital from 1897 to 1909 and again briefly during the Korean War. It was designated a city in 1949.

Strategically located in the fertile Kyŏnggi plain, Suwon naturally developed as a centre of Korean agriculture. Its economic life is largely concerned with handling the farm products of the surrounding countryside, such as rice, beans, wheat, vegetables, silk cocoons, pigs and, in particular, cattle. Suwon's factories produce mainly cotton and rayon goods, alcoholic beverages and bricks. Several agricultural research facilities are located in the city, such as the Institute of Agricultural Technology, the Sericulture Research station, and the College of Agriculture of Seoul National university. (E. W. WA.)

SUYUTI, AL- (ABU-AL-FADL ABD-AL-RAHMAN IBN ABI BAKR JALAL-AL-DIN AL-SUYUTI) (1445–1505), Arabic encyclopaedic author, whose works deal with almost every subject, the Islamic religious sciences predominating. He was the son of a judge of Asiyut in Egypt. Tutored by a Sufi friend of his father's, he was precocious, being already a teacher in 1462. In 1486 he was appointed to a chair in the mosque of Baybars in Cairo. From 1501 until his death he worked in seclusion on the island of Rauda.

His works number several hundred, and, though many are short booklets, others are large-scale works. He was co-author of *Tafsir al-Jalalain,* a word-by-word commentary on the *Koran,* the first part of which was written by Jalal-al-Din al-Mahalli (1389–1459). His *Itqan fi 'Ulum al-Koran* is a well-known work of koranic exegesis. Among his historical works is a history of the caliphs.

Suyuti was a compiler of genius rather than an original writer, but it is precisely his ability to select and abridge which makes his books so useful. This faculty, together with his keen, analytical mind, characterizes his best work, *al-Muzhir fi 'Ulum al-Lugha,* a guide to the Arabic science of lexicography or philology, in which the subject is treated in 50 aspects or categories. The work has been much used by European Arabists, especially by E. W. Lane (*q.v.*) in the introduction to his lexicon.

See C. Brockelmann, *Geschichte der arabischen Literatur,* vol. 2, pp. 143–158 (1902), and supplement to vol. 2, pp. 178–198 (1938). (J. A. HO.)

SUZDAL, PRINCES OF. In Russian history the area between the Oka river and the upper Volga was called the Suzdal land or *zemlya Suzdalskaya.* In the 10th and 11th centuries A.D. it was a remote corner of the Russian world, but during the 12th and 13th centuries it grew rapidly in political and economic importance, becoming a cradle of the Great Russian nationality. There the immigrants from the Russian south, which was devastated by nomadic invasions, found a quieter life and gradually merged with the scattered and peaceful indigenous Finnish tribes to form the bulk of the Russian peasantry.

The first important prince of the region was Andrew (*q.v.;* Russ. Andrei Yurievich) Bogolyubski, who ruled from 1157 to 1174. He disliked the old established cities of this area—Rostov and Suzdal with their influential boyar class and their old custom of popular assemblies (*veche*)—and moved his capital to Vladimir on the Klyazma river. He successfully colonized and organized the area,

becoming the most powerful among the contemporary Russian princes. His brother Vsevolod III (1176–1212) successfully continued Andrew's policies. Vsevolod's power and influence were felt by other Russian princes, as well as by the rich and proud city-state of Novgorod the Great, which depended on Suzdalia for grain supply. But the political structure erected by Andrew and Vsevolod did not endure. The Suzdal princes regarded their territories as their private property and, accordingly, divided them by testaments among their sons; these separated parts became the appanages or *udely*. During the 13th and 14th centuries Suzdalia thus disintegrated gradually into several lesser principalities, which recognized the seniority of the grand prince of Vladimir only nominally. On the other hand, the Tatar conquest (in 1237–40) made the grand prince of Vladimir, as all other Russian princes, an obedient vassal of the Tatar khan.

Prince Konstantin Vasilievich (1332–55) succeeded in building the grand principality of Suzdal and Nizhni Novgorod, with the capital in Nizhni Novgorod (now Gorki) from 1350; and his son Dimitri even became grand prince of Vladimir in 1359–62. Soon, however, the throne of Vladimir returned to the grand prince of Moscow (*q.v.*); and in 1392 Prince Vasili I Dimitrievich of Moscow, empowered by the khan Tokhtamysh, seized the region of Nizhni Novgorod and annexed it to Moscow's possessions.

See A. V. Ekzemplyarski, *Velikie i udelnye knyazya severnoi Rusi,* 2 vol. (1889–91). (S. G. Pu.)

SUZERAINTY was a term used in the middle ages to describe the relation between the feudal lord and his vassal. According to feudal law the vassal owed certain duties to the lord; he promised fidelity and service, and the lord was bound to perform reciprocal duties, not very clearly defined, to the vassal—*Dominus vassallo conjux et amicus dicitur* ("a lord is called the partner and friend of his vassal"). (*See* Feudalism and articles there cited.)

In modern times the term has been used by analogy to describe a relationship of dependency between states of unequal power, the superior state being the "suzerain" and the dependent state the "vassal." W. E. Hall described the relationship thus: "States under the suzerainty of others are portions of the latter which during a process of gradual disruption or by the grace of the sovereign have acquired certain of the powers of an independent community, such as that of making commercial conventions, or of conferring their exequatur on foreign consuls." (*International Law,* 8th ed., p. 32.) Suzerainty, however, is not to be confused with sovereignty. "It is a kind of international guardianship, since the vassal state is either absolutely or mainly represented internationally by the suzerain State." (L. F. A. Oppenheim, *International Law,* 8th ed., ed. by H. Lauterpacht, vol. i, p. 189 [1955].)

On the whole, usage favours a distinction between suzerainty and protectorate in that a protectorate flows from, or is a reduction of, the sovereignty of the protected state, while suzerainty is conceived as derived from, and a reduction of, the sovereignty of the dominant state. Moreover, a protectorate usually implies the existence of a treaty defining the relationship. It is not possible to ascribe any precise juristic significance to the term suzerainty, however. In any particular case the terms of the relationship must be deduced from the events or instruments by which it came into being, and not from the term used to describe it.

The subject is now of no more than historical interest because there are no longer any vassal states remaining. Examples of states under suzerainty were Bulgaria from 1878 to 1908 and Egypt from 1840 to 1914, during which periods both these countries were under the suzerainty of Turkey. The term was also used to describe the relationship which formerly existed between Great Britain and the Indian native states (*see* Interpretation act, 1889, s. 18). These states had no international relations whatever, either between themselves or with foreign states. Yet the rulers of these states successfully claimed in English courts the privilege and immunities which are by international law accorded to the heads of states when abroad; see *Statham* v. *Statham and the Gaekwar of Baroda* [1912] P. 92 and *Sayce* v. *Amir of Bahawalpur state* [1952] AU E.R. 32b. *See* Mandate; Protectorate; Sovereignty; Spheres of Influence.

SUZUKI, DAISETZ TEITARŌ (1870–), renowned interpreter of Zen Buddhism, especially to the west, was born Oct. 18, 1870, in Kanazawa, Japan. During his college days in Tokyo he was trained under two great Zen masters, Imakita Kōsen and Shaku Sōyen. Shaku Sōyen represented Mahayana Buddhism at the World Parliament of Religions, held in Chicago, Ill., in 1893, and there he met Paul Carus (1852–1919), a philosopher interested in oriental religions. Subsequently, Shaku Sōyen recommended Suzuki to become Carus' assistant, and Suzuki went to La Salle, Ill., where he helped Carus in the translation of the *Tao Te-Ching* and other works. During his 11 years at La Salle, Suzuki translated Asvaghosha's *Discourse on the Awakening of Faith in the Mahayana* (1900) and also completed his *Outlines of Mahayana Buddhism* (1907). He visited Europe in 1908. Upon his return to Tokyo in 1909, he taught English at the Peers' school as well as at Tokyo Imperial university.

In addition to his interest in Zen Buddhism, Suzuki was also influenced by Ralph Waldo Emerson. In 1921 he accepted the chair of religious studies at Ōtani university, Kyōto (emeritus 1960), where he also served for 20 years as the editor of an English-language journal, *The Eastern Buddhist.* In 1936–37 he was sent by the Japanese government to lecture on Zen and Japanese culture in Europe and America. Again after World War II Suzuki traveled abroad, participating in the Conferences on Philosophy East and West at Hawaii (1949 and 1959) and lecturing at U.S. and European universities. In 1960 he toured India as a guest of the Indian government.

Suzuki is the author of more than 130 major books and numerous articles, written in Japanese and English. Important among his English writings are: *Essays in Zen Buddhism,* three volumes (1927–34), *Studies in the Lankāvatāra Sūtra* (1930; his doctoral dissertation), *An Index to the Lankāvatāra Sūtra,* Nanjiō edition (1933 and 1934), *The Training of the Zen Buddhist Monk* (1934), *An Introduction to Zen Buddhism* (1934), *Manual of Zen Buddhism* (1936), *The Zen Doctrine of No-Mind* (1949), *Living by Zen* (1949), *Studies in Zen* (1955), *Mysticism: Christian and Buddhist* (1957) and *Zen and Japanese Culture* (1959). The Japanese government in 1949 conferred upon him a cultural medal and made him a member of the Japan academy. (S. Fu.)

SVALBARD is part of the kingdom of Norway and comprises all islands in the Arctic ocean between long. 10° and 35° E. and lat. 74° and 81° N. (Vestspitsbergen, Nordaustlandet [North East Land], Edgeøya [Edge Island], Barentsøya [Barents Island], Prins Karls Forland [Prince Charles Foreland] and a number of smaller islands), Bjørnøya (Bear Island), Hopen (Hope Island), Kong Karls Land (Wiche Islands) and Kvitøya (Gillis Land). The total area of Svalbard is 23,958 sq.mi. Spitsbergen (*q.v.*) covers 23,641 sq.mi., Bjørnøya 69, Kong Karls Land 128 and Kvitøya 102 sq.mi., respectively. Sovereignty over Svalbard was given to Norway by a treaty signed in Paris on Feb. 9, 1920, and the Norwegian colours were hoisted in Longyearbyen on Aug. 14, 1925. Svalbard is administered from Norway partly by the ministry of industry and partly by the ministry of justice. A governor (*sysselmann*) has his residence in Longyearbyen. He is also chief of police, notary public and assistant judge. An inspector of mines (*bergmester*) supervises mining activities. Norwegian criminal and civil law is in force. A mining ordinance gives the subjects of all signatory powers to the treaty equal rights to

exploit mineral deposits.

The name Svalbard means "the cold coast," an Old Norse name. According to the *Icelandic Annals,* Svalbard was discovered in 1194, four days' (*daegra*) sailing from Cape Langanes on Iceland. It is probable that this land was identical with Spitsbergen. The name Svalbard was introduced as an administrative name for all the islands when Norway assumed sovereignty. (A. K. O.)

SVEDBERG, THEODOR (THE) (1884–), Swedish chemist and Nobel prize winner in 1926, is distinguished for the development of physical chemical methods of studying colloids and macromolecules, particularly that of ultracentrifugation. He was born at Fleräng, near Valbo, Swed., on Aug. 30, 1884. From 1904 he studied chemistry at Uppsala university, where he became professor of physical chemistry (1912–49), professor emeritus (1949), director of the Institute of Physical Chemistry (1931–49) and director of the Gustaf-Werner Institute of Nuclear Chemistry (1949).

The development of the ultracentrifuge made a profound and timely contribution to the study of large molecules. In this instrument the migration of large molecules in solution under the influence of a strong centrifugal force (up to 100,000 times gravity) can be observed and related to the molecular size and shape. By this means Svedberg demonstrated that the molecules of certain pure proteins are all of one size. Thus, the ultracentrifuge can sometimes, in the characterization of a new protein, show the presence of contaminating substances. In the field of high polymers the behaviour of long chain molecules, particularly cellulose, in the ultracentrifuge has contributed to the elucidation of their properties. For these and other studies in colloidal systems Svedberg was awarded the Nobel prize. (K. A. SY.)

SVENDBORG, a seaport of Denmark, capital of the *amt* (county) of its name, on the island of Fyn. Pop. (1960) 23,824. The narrow Svendborg Sund separates Fyn from the lesser islands of Taasinge (245 ft.) and Turø. Inland there is also elevated ground, the Ovinehøi. The harbour is accessible to vessels drawing 20 ft. Near the town are the ruined castle of Ørkild, the watering place Christiansminde, and the orchards of Gammel Hestehave, where wine is produced.

SVENDSEN, JOHANN SEVERIN (1840–1911), Norwegian composer and conductor who helped establish the Norwegian national school of music. Born at Christiania (Oslo), Sept. 30, 1840, he started his career as a military bandmaster; a scholarship enabled him to study at the Leipzig conservatory. After conducting symphonic concerts in Oslo for several years, he became court *Kapellmeister* in Copenhagen in 1883, where he lived until his death on June 14, 1911. Svendsen, regarded as the most outstanding Norwegian conductor of his time, was certainly one of the most distinguished composers of Scandinavia. His chamber works include a string octet and his orchestral works four Norwegian rhapsodies, based on Norwegian folk tunes, the overture *Carnival in Paris* and the *Norwegian Artists' Carnival.*

SVERDLOVSK, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., was formed in 1934. Pop. (1959), 4,044,416. Area 74,440 sq.mi. The *oblast* is roughly triangular, with its western side lying along the crest line of the Urals, which within the *oblast* reach a maximum height of 5,148 ft. in Gora Konzhakovski Kamen. The *oblast* includes the eastern slope of the Urals and stretches out to the flat West Siberian plain (Zapadno-Sibirskaya Nizmennost). Its southwestern corner extends across to the western flank of the Urals in the upper Ufa basin. The main rivers draining eastward are the Tavda, with its headstreams Lozva and Sosva, and the Tura, with its tributaries Nitsa and Pyshma. The climate is sharply continental, January average temperatures ranging from −16° C. (3° F.) in the southwest to −20° C. (−4° F.) in the north, and July averages about 16°–17° C. (61°–63° F.). Rainfall is about 16 in. a year on the lowland, rising to 24 in. on the Urals. Almost the entire *oblast* is covered in taiga forest of pine, stone pine, birch and larch, with spruce, fir and oak appearing in the southwest. Only the highest summits of the Urals are bare; in the extreme south the *oblast* enters the forest-steppe zone, with alternating birch groves and grass steppe.

Of the 1959 population, more than three-quarters were urban dwellers, a reflection of the *oblast's* role as part of the Urals industrial region. The largest of the 39 towns and 88 urban districts are the administrative centre Sverdlovsk (778,602), Nizhni Tagil (338,501), Kamensk-Uralski (141,019), Serov (97,882), Asbest (*qq.v.;* 60,053), Pervouralsk (91,034), Krasnoturinsk (61,990), and Revda (54,870).

Like all the Urals region, the *oblast* is exceptionally rich in the range and quantities of minerals. Iron ore is mined in the Serov-Ivdel area, at Nizhni Tagil and at Kushva. Manganese occurs at Ivdel; chromium at Kluchevsk; cobalt, nickel, tungsten and vanadium near Sverdlovsk; beryllium near Asbest. Copper is mined at several places including Alapayevsk, Degtyarsk, Krasnouralsk and Kirovgrad. Asbest has the largest deposits of asbestos in the U.S.S.R. Bauxite is found at Kamensk-Uralski and Serov, and Polevskoi is a major producer of artificial cryolite. Platinum and gold are widespread, and zinc and sulfur deposits are worked. Coal and lignite are of inferior quality. Based on these minerals a large metallurgical industry developed in the 1930s and received further impetus during World War II. Nizhni Tagil has one of the largest iron and steel plants of the Soviet Union and smaller works are located at Serov, Kushva, Pervouralsk, Revda and Severski. Sverdlovsk and Nizhni Tagil are centres of large-scale heavy engineering. Nonferrous metals are processed in Krasnoturinsk, Krasnouralsk, Kirovgrad, Kamensk-Uralski and Revda (copper). There is a thriving chemical industry producing industrial chemicals, plastics, fertilizers and medical preparations. Timber working is widespread and well developed. The chief lack of the *oblast* is fuel. Coking coal is brought from Karaganda (Kazakh S.S.R.) and the Kuzbass (Kuznetsk basin) and natural gas is piped from Berezovo in the northern Urals. Agriculture is relatively unimportant and largely confined to the southeast (around Irbit), where grains and potatoes are grown. Market gardening is important around the towns.

All the main centres are connected by a rail network which is linked to the Trans-Siberian railroad. (R. A. F.)

SVERDLOVSK (formerly YEKATERINBURG), a town and administrative centre of the *oblast* of the same name in the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the eastern slope of the Ural mountains on both banks of the Iset river, a tributary of the Tobol, 850 mi. E. of Moscow. Pop. (1959) 778,602. The town has two 18th-century cathedrals and is the leading cultural and educational centre of the Urals region. It has a musical *conservatoire* and opera and dramatic theatres; a polytechnic; and institutes of mining, forestry, agriculture, medicine, law and teaching. It is also the seat of the Urals A. M. Gorki State university (founded 1920) and of the Urals branch of the U.S.S.R. Academy of Sciences.

Sverdlovsk is an important railway junction. Seven lines radiate from it to all parts of the Urals and the rest of the Soviet Union, including Moscow, Leningrad and Omsk. Its chief importance lies in heavy engineering, for which it is one of the largest centres of the U.S.S.R. Among its wide range of engineering products are machines for the metallurgical and chemical industries; mining and oil drilling equipment; turbines, diesels, ball bearings, electrical equipment, cables, precision instruments, refrigerators and bicycles. The chemical and rubber industries (plastics, tires) are well developed. Steel manufacture, utilizing pig iron from other centres and scrap, is still maintained but is less important than in other Ural centres. Light industrial products include footwear and other leather goods; clothing, tobacco and foodstuffs. A traditional craft is the cutting of diamonds and other precious stones.

Sverdlovsk has its origin in the establishment there in 1721 of the Verkhne-Isetski (Upper Iset) ironworks and fortress by V. N. Tatischev, historian, traveler and government functionary; and the settlement became the administrative centre for all the ironworks of the Urals. It was named Yekaterinburg in 1723 for Catherine I, wife of Peter I the Great. Other ironworks developed in the vicinity, and its industrial and administrative importance was increased from 1783 when the Great Siberian highway was built through it. The first railway arrived from Perm in 1878 and

several other lines were laid from it during the next fifty years. After the Revolution Yekaterinburg was the last place of imprisonment of the tsar Nicholas II and his family, who were shot there on the night of July 29–30 (N.S.; July 16–17 O.S.), 1918, to prevent their escape to Kolchak's White Russian army which was advancing toward the town. Yekaterinburg fell to the White troops a week later and was recaptured by the Red army in July 1919. It was renamed Sverdlovsk for the Bolshevist Yakov Sverdlov in 1924. Evacuation of industry to the Urals during World War II gave further impetus to expansion. (R. A. F.)

SVERDRUP, JOHAN (1816–1892), Norwegian statesman, was born at Jarlsberg on July 30, 1816. His father, Jakob Sverdrup, was a land steward, and the founder of the first school of agriculture in Norway. Johan entered the *storting* in 1850. He built up a strong political party, supported by the peasantry, and in 1872, secured a bill for the admission of ministers to the *storting*, which was a step to parliamentary control. King Charles XV refused his sanction to this bill, and on its third passing in 1880 Oscar II opposed his absolute veto. Sverdrup then proposed the proclamation of the law in defiance of the king's action. The retirement of Frederik Stang removed Sverdrup's chief political opponent from the field. He was aided in his campaign by Bjørnstjerne Bjørnson, and after a series of political crises he became prime minister in June 1884. He soon found himself at issue with Bjørnson on church matters; although during his term of office no fewer than eighty-nine measures, many of them involving useful reforms, became law, he failed to satisfy the extremists and was driven to rely on the moderate Liberals. He was compelled to retire in 1889, and died on Feb. 17, 1892, at Christiania.

SVYATOSLAV I (Svyatoslav Igorevich, d. 972), grand prince of Kiev from 945 and a hero of early Russian history, was the son of Igor and Olga (*qq.v.*). After coming of age, he dedicated all his efforts to bold military expeditions, leaving his mother, Olga, in Kiev to take care of the internal affairs of the state until her death in 969. The Russian chronicle describes the last heathen Russian prince, who "stepping light as a leopard . . . carried with him neither wagons nor kettles . . . nor did he have a tent. . . . He sent messengers to the other lands announcing his intention to attack them." Between 963 and 965 he defeated the Khazars on the lower Don and the Ossetians and Circassians in the northern Caucasus and stormed the capital of the Volga Bulgars. When the Byzantine government, engaged in a war against the Balkan Bulgars, asked Svyatoslav for help, he invaded Danubian Bulgaria in 967 and defeated the Bulgars. He then refused to cede his conquests to the Byzantines, declaring his intention of establishing his capital in Pereyaslavets (Pereyaslav-Khmelnitski) on the Danube and founding a Russo-Bulgarian empire. The Byzantine emperor John I Tzimisces, having gathered overwhelming forces, defeated Svyatoslav's relatively small army and forced him to abandon any claims to Balkan territory (971). In the spring of 972, while Svyatoslav was returning to Russia with a small retinue, he was ambushed by the Pechenegs near the cataracts of the Dnieper and killed.

SWABIA, Suabia or Suevia (Ger. *Schwaben*), one of the stem-duchies of mediaeval Germany, taking its name from the Suevi, a tribe who inhabited the district in the first century of the Christian era. They were joined by other tribes, and the district was called Alamannia, until about the 11th century, when the form Swabia began to prevail. In 496 the Alamanni were defeated by Clovis and governed by dukes dependent on the Frankish kings. In the 7th century the people were converted to Christianity, bishoprics were founded at Augsburg and Constance, and in the 8th century abbeys at Reichenau and St. Gall. The Alamanni had gradually thrown off the Frankish yoke, but in 730 Charles Martel again reduced them to dependence.

The duchy, bounded by the Rhine, the lake of Constance, the Lech and Franconia, was ruled by the counts of Raetia, one of whom, Burkhard, took the title of duke in 917 and was recognized as such by King Henry I., the Fowler, in 919. On his death in 926 he was succeeded by Hermann, a Franconian noble, who married his widow. When Hermann died in 948 Otto the Great gave the duchy to his own son Ludolf, who had married Hermann's daughter Ida; but he reduced the ducal privileges and appointed counts palatine to watch the royal interests. Ludolf revolted and was deposed, and other dukes followed in quick succession. During these years the Swabians were loyal to the kings of the Saxon house. In 1077, Rudolph, count of Rheinfelden, as duke, was chosen German king in opposition to the emperor Henry IV., but found little support in Swabia, which was given by Henry to his faithful adherent, Frederick I., count of Hohenstaufen. Frederick II. succeeded his father in 1105, and was followed by Frederick III., afterwards the emperor Frederick I. The earlier Hohenstaufen increased the imperial domain in Swabia, where they received steady support, although ecclesiastical influences were very strong. After numerous changes, the chief authority in Swabia in 1268 fell to the counts of Württemberg, the margraves of Baden, the counts palatine of Tübingen and the counts of Hohenzollern.

SWABIAN LEAGUE, an association of German cities, principally in the old duchy of Swabia. The cities had attained prosperity under the Hohenstaufen emperors, but on the extinction of that house in 1268, they were ill-defended against aggression by succeeding dynasties.

In 1331, 22 Swabian cities, including Ulm, Augsburg, Reutlingen and Heilbronn, formed a league at the instance of the emperor Louis the Bavarian, who in return for their support promised not to mortgage any of them to a vassal. The count of Württemberg was induced to join in 1340. Under Charles IV. the lesser Swabian nobles began to combine against the cities, and formed the *Schlegelerbund* (from *Schlegel*, a maul). Civil war ensuing in 1367, the emperor, jealous of the growing power of the cities, endeavoured to set up a league under his own control, for the maintenance of public peace. The defeat of the city league by Eberhard II. of Württemberg in 1372, the murder of the captain of the league, and the breach of his obligations by Charles IV., led to the formation of a new league of 14 Swabian cities led by Ulm in 1376. This league triumphed over the count of Württemberg at Reutlingen in 1377, and the emperor having removed his ban, it assumed a permanent character, set up an arbitration court, and was rapidly extended over the Rhineland, Bavaria and Franconia. Its professed aims were the maintenance of the imperial status of the constituent cities, the security against sale or mortgage and against excessive taxation, the protection of property, trade and traffic, and the power to suppress disturbances of the peace. There is no trace of co-operation with the Hanseatic towns.

For nearly a century there was no great effort at federation among the Swabian cities, though there were partial and short-lived associations. The growing anarchy in Swabia, where the cities were violently agitated by the constant infringement of their liberties (*e.g.*, the annexation of Regensburg by Bavaria in 1486), induced Frederick III., who required men and money for the Hungarian War, to conciliate the cities by propounding a scheme of pacification and reform. His commissioner, Count Hugo of Werdenberg, met the Swabian estates at Esslingen, and on Feb. 14, 1488, the Great Swabian League was constituted. There were four constituent parties, the archduke Sigismund of Austria, Count Eberhard V. of Württemberg, who became the first captain of the league, the knightly league of St. George, and lastly 22 Swabian imperial cities. The league received a formal constitution with a federal council consisting of three colleges of nine councillors each, a captain and a federal court with judicial and executive powers. The armed force which was to police Swabia consisted of 12,000 foot and 1,200 horse, each party contributing one-fourth. The league gained strength by the speedy accession of Augsburg and other Swabian cities, the margraves of Brandenburg-Ansbach, Bayreuth and Baden, the four Rhenish electors, etc., and in 1490 of Maximilian, king of the Romans, whom the league had helped to rescue from the hands of the Netherlanders in 1488. It did not render him the support he expected in his foreign policy, but it performed its primary work

of restoring and maintaining order with energy and efficiency. In 1492 it compelled Duke Albert of Bavaria to renounce Regensburg; in 1519 it expelled the turbulent duke, Ulrich of Württemberg who had seized Reutlingen, and it sold his duchy to Charles V; and in 1523 it defeated the Franconian knights who had taken up arms with Franz von Sickingen. In 1525 Truchsess, the league captain, aided by the forces of Trier and the palatinate, overthrew the rebel peasants of Königshofen on the Tauber and at Ingolstadt. The league, after several renewals, expired on Feb. 2, 1534, its dissolution being due to the Reformation. Futile attempts were made to renew it, in 1535 by the Bavarian chancellor, Eck, and in 1547 by Charles V.

(A. B. G.)

SWAHILI, *Wa-Swahili* from Arabic *sahil,* "coast," a term applied to the inhabitants of the East African coast from Mogadishu to Kilwa and of the islands of Zanzibar, Pemba and Comoro. They are a mixture of African and Arab, the African element being based on a local Bantu people with a large admixture of slaves from all over East and Central Africa. Their language, Ki-Swahili, has a purely Bantu grammar and a large Arabic vocabulary.

The Swahili are not a tribe, but a people united by a common language and religion (Islam). Though their culture is largely Islamic, there remain many traces of their African origin and some Indonesian and other non-African elements. The chief Swahili dialects are Ki-Unguja of Zanzibar (now the standard form); Ki-Mvita of Mombasa; and Ki-Amu of Lamu. Older forms are Ki-Ngozi and Ki-Kae. A large body of Swahili poetry and prose in Arabic comprises secular and religious works. (G. W. B. H.)

SWAHILI LANGUAGE. Swahili (Kiswahili) is a Bantu language spoken primarily on the east coast and islands of Africa between Lamu Island in the north and the mouth of the Ruvuma river in the south. It is spoken sporadically as far north as Mogadishu and there appear to be Swahili-speaking enclaves in Somaliland; it has also been heard as far south as Mozambique. A form of Swahili is also spoken on the west coast of Madagascar. People who speak Swahili as their sole mother tongue are usually referred to as Waswahili, but those who live in the larger towns prefer to be known as Waarabu ("Arabs"). There are about 15 main Swahili dialects as well as several pidgin forms in use.

Swahili as a lingua franca is current in: (1) Tanganyika, where it is the language of administration and primary education; (2) Kenya, where it is also the main language of administration and primary education, though alternative languages have been recognized in certain parts of the colony; (3) Uganda, where it is in competition with local languages; (4) Republic of The (former Belgian) Congo, where a form of Swahili (sometimes called Kingwana) is one of the four permitted languages of administration and where its use in education depends largely on mission society policy, although there are a few communities where Swahili appears to be the mother tongue. Swahili is regarded, with Nyika (including Giryama), as a language group closely related to the Taita language group.

Although modern Swahili contains an enormous vocabulary of Arabic borrowings (as well as borrowings from Persian, Hindi, Portuguese and English), in its grammatical behaviour it is characteristically Bantu; *i.e.,* (1) it has a large vocabulary of word roots traceable to a common Bantu stock; (2) its nouns are divided into classes, distinguished by typical prefixes, for the most part groupable in pairs denoting singular and plural; *e.g., m-tu,* pl. *wa-tu* ("person"), *ki-tu,* pl. *vi-tu* ("thing"), etc.; (3) verbs, adjectives, demonstrative and possessive forms are brought into agreement with nouns by means of prefixes; *e.g., wa-tu w-etu wa-le wa-kubwa wa-mekuja* ("those big people of ours have come"); (4) verb stems may be extended by means of suffixes, each with a particular nuance of meaning; *e.g., funga* ("shut"), *fungwa* ("be shut"), *fungika* ("become shut"), *fungia* ("shut for"), *fungisha* ("cause to shut"), *fungua* ("open"), etc.

Origin and History.—The name Swahili is derived from the Arabic *swahil* ("coasts"). Contact between Arabia and the east coast of Africa was made as early as the 1st century A.D. when, according to the *Periplus of the Erythraean Sea,* the people of Muza (in southern Arabia) "sent thither many large ships, using Arab captains and agents, who are familiar with the natives and intermarry with them." But the earliest known settlement at Pate is said to have been founded in A.D. 689. During the next 600 years other cities such as Lamu, Malindi, Mombasa and Kilwa were founded and reached a high level of civilization, until eclipsed by the Portuguese conquests in the early 16th century. After the Arabs had returned and ousted the Portuguese in the early 18th century and transferred their court from Oman to Zanzibar in 1832, Swahili came into its own, enhanced by the intermarriage of the Arab overlords with the coastal people.

During the early 19th century the spread of Swahili inland received a great impetus through its being the language of the Arab ivory and slave caravans, which penetrated as far north as Uganda and as far west as the upper reaches of the Congo (Lualaba) river. It was later adopted by Europeans. It has been challenged by local vernaculars in certain regions and there has also been a tendency among some Africans to prefer the metropolitan language as lingua franca. Others, however, look to Swahili as the future national language of East Africa.

Literature.—The earliest literature in Swahili was written in the Arabic script and a certain amount still exists in manuscript. Some has been published. In the latter half of the 19th century, the roman alphabet was successfully applied to Swahili by missionaries and the first complete Bible was produced by 1891 in the Mvita (Mombasa) dialect. For several years there was strong rivalry between this dialect and that of Zanzibar (Unguja), until the latter obtained official recognition as "standard" in the 1920s. Afterward the written language progressed apace, under the encouragement of the Interterritorial Language (Swahili) committee —later the East African Swahili committee—and the years after World War II saw an enormous development. Besides further Bible translations (including the "Union Version" of 1950) and a spate of government-inspired textbooks for schools and adult literacy campaigns, there are about 60 Swahili newspapers and broadsheets in East Africa and a dozen in the Congo area. Indigenous authors have gradually come to the fore, among whom Shaaban Robert is outstanding. *See* BANTU LANGUAGES.

SWALLOW, the name for birds of the passerine family Hirundinidae. With graceful flight and much twisting and turning, the swallows seek their insect food in the air. The features that characterize the family are adaptatious for this: long pointed wings, small feet, short broad bill and wide gape. About 74 species of small to medium-sized birds comprise the family. Their colours are not gaudy, but many species have rufous or glistening white and iridescent deep-blue or green in the plumage. The range of the family is almost world-wide. The species breeding far north and south are strongly migratory, and some make long journeys across the equator to reach their winter quarters.

Swallows like company. They gather to feed in favourite spots; great numbers may assemble in the late afternoon to roost together during the night, and many species nest in colonies. Certain species come commonly about human habitations and nest on buildings or in nest boxes prepared for them. Though hardly songsters, their twitterings and chirping notes are pleasant, and this plus their familiar habits and their returning to temperate climates with the spring has given them a friendly place in people's minds and in literature. Their nesting is various: in a hole in a tree or bank, in a burrow dug by themselves in an earthen bank, a

saucer-shaped structure on a ledge of rock or a building, or a retort-shaped structure of mud pellets stuck to the side of a cliff or a building. There may be up to six eggs, pure white or spotted.

In a restricted sense "the swallow" is used in England for a familiar species, *Hirundo rustica,* called barn swallow in the United States, where it also is the best known species. The name martin (*q.v.*) is used for some swallows. (A. L. Rd.)

SWAMMERDAM, JAN (1637–1680), Dutch naturalist and biologist, who first described the red blood corpuscles and made the finest collection of microscopic observations that have ever been published, was born on Feb. 12, 1637, at Amsterdam. His father was an apothecary and naturalist who had a museum of curiosities, and Swammerdam started his career by helping with the museum. He went to Leiden university in 1661, graduating in medicine in 1667. Neglecting his practice, he became a pioneer of microscopy. He made a comparative study of insect life histories, which he classified according to the type of metamorphosis. He held that his observations supported the preformation theory of embryology. He went into minute details of the internal anatomy of the mayfly and the bee; observed the cleavage of the frog's egg and the subsequent segmentation and studied the anatomy of tadpole and adult; described the ovarian follicles of mammals in the same year as Regnier de Graaf (*q.v.;* 1672); and evolved improved techniques of injection which aided his study of human anatomy. Swammerdam discovered the valves of the lymphatics and was the first to describe the red blood corpuscles (1658). By a well-devised experiment he showed that the muscles alter in shape but not in size during contraction; this contradicted the current theory that a material fluid passed down the nerves to cause movement. He was the first to draw the sporangia of a fern. Deeply religious and somewhat unstable, he became for a time, after a quarrel with his father, a disciple of Antoinette Bourignon (*q.v.*).

Swammerdam died in Amsterdam on Feb. 15, 1680, after a period of deep spiritual and bodily misery.

His books, some of them magnificently illustrated were: *Tractatus physico-anatomico-medicus de respiratione usuque pulmonum* (1667); *Allgemeene verhandeling van bloedeloose diertjens* (1669); *Miraculum naturae seu uteri muliebris fabrica* (1672); and *Ephemerae vita* (1675). H. Boerhaave published a collection of Swammerdam's manuscripts, *Biblia naturae* (1737–38). (A. C. Ce.; X.)

SWAMP, a tract of saturated, miry, spongy ground occurring under conditions of impeded surface or internal drainage of substrata abundantly supplied with water from precipitation, ground water, tides or other sources and which may be seasonally or perennially subject to flooding. Swamps are abundant and extensive on the low flat-lying terrain of seacoasts, lake basins and stream valleys, may be widespread on uplands with low drainage gradients and often occur on steep slopes where ground-water seepage is abundant. Development of swamps is favoured by wet climates but they are common in arctic areas with permanent frost despite low precipitation.

In popular usage the term "swamp" indiscriminately includes bogs, marshes, fens, moors, heaths, muskegs and other related terrain features and may be distinguished from these commonly intergrading features only with difficulty even in local areas. Some characteristic properties of swamps include soft, mineral-rich substrata of well-mixed inorganic and organic fractions, little or no peat accumulation, absence of the floating mats of vegetation typical of bogs, relatively good aeration and filling by silting, or if by organic accumulation *in situ,* the materials added from the bottom upward.

Swamp vegetation is usually dense, of great variety and, depending upon the stage of development in relation to the changing environment, may consist principally of herbaceous species (cattails, grasses, sedges), woody shrubs (willow, alder, buttonbush), coniferous trees (white spruce, bald cypress) or broadleaved deciduous trees (willow, cottonwood, sycamore, cotton gum, red maple).

Examples in the United States are the mangroves of coastal Florida, the partially marshy Dismal swamp of Virginia and North Carolina and the Okefinokee swamp of Georgia. *See* also Marsh. (M. E. B.)

SWAN, SIR JOSEPH WILSON (1828–1914), English physicist and chemist who invented the dry photographic plate and a prototype of the electric light, was born at Sunderland, in County Durham, on Oct. 31, 1828. After serving his apprenticeship with a druggist in his native town, he became first assistant and later partner in a firm of manufacturing chemists in Newcastle.

Among its operations this firm included the manufacture of photographic plates, and thus Swan was led to one of the advances in photography with which his name is associated—the production of dry plates, the outcome of an original observation made by him on the effect of heat in increasing the sensitiveness of a gelatine bromide of silver emulsion. In 1862 he patented the first commercially practicable process for carbon printing in photography (*see* Photography). In 1879 Swan patented bromide paper.

In 1860 he produced an electric lamp with a carbon filament which was formed by packing pieces of paper or card with charcoal powder in a crucible and subjecting the whole to a high temperature. The carbonized paper thus obtained he mounted in the form of a fine strip in an evacuated glass vessel and connected it with a battery to Grove's cells, which though not strong enough to raise it to complete incandescence, were sufficient to make it red-hot. This was substantially the method adopted by Thomas A. Edison nearly 20 years later.

Subsequently Swan devised a cotton thread "parchmentized" by the action of sulfuric acid, and on Oct. 20, 1880, he gave at Newcastle the first public exhibition on a large scale of electric lighting by means of glow lamps. In another method devised by him, first exhibited in 1897, collodion was squirted into a coagulating solution and the tough threads thus obtained carbonized by heat. He also devoted attention to apparatus for measuring electric currents, to the improvement of accumulators and to the conditions governing the electrodisposition of metals.

Swan was knighted in 1904. Holding many honours, he died at Warlingham, Surrey, on May 27, 1914.

SWAN, the name for birds of a group that contains the largest of the waterfowl (family Anatidae). With long necks and short legs, swans are most at home on water, where they feed on aquatic plants. They also eat some grass and grain, though they walk somewhat awkwardly on the land.

A. W. AMBLER FROM NATIONAL AUDUBON SOCIETY

MUTE SWAN (CYGNUS OLOR) AND CYGNET

There are seven kinds of swans. Five, all white in colour, live in the northern hemisphere; a black-necked swan, *Cygnus melancoriphus,* lives in southern South America; and a black one, *Chenopis atrata,* lives in Australia and New Zealand, having been introduced into the latter country. The common swan of ornamental ponds everywhere is the mute swan, *Cygnus olor,* native of northern Europe and Asia and easily recognized by the knob on its forehead. It became a wild bird in Long Island, N.Y., after it escaped from estate ponds. Because of its pugnacious disposition and voraciousness, it poses a threat to other waterfowl.

American species are the arctic nesting whistling swan (*Olor columbianus*), a race of the Bewick's swan of Eurasia, and the rare trumpeter swan (*O. buccinator*) of Montana, Wyoming and western Canada. The latter was threatened with extinction, but has increased and extended its range into southern Alaska. The whistling swan winters in large numbers in the Currituck sound area of North Carolina and Virginia. On northward migration, flocks occasionally alight in the Niagara river and, unable to take flight as they are swept through the rapids, pass over the falls to their destruction. Swans have figured widely in song, story and mythology. Among the myths is the song of the dying swan. (Dn. A.)

SWANAGE, a seaside holiday town and urban district in the South Dorset parliamentary division of Dorset, Eng., 27 mi. E.S.E. of Dorchester by road. Pop. (1961) 6,062. Area 4.3 sq.mi. It lies in a sandy bay backed by precipitous chalk cliffs with numerous caves. Swanage bay was the scene of Alfred the Great's naval victory over the Danes in 877. Purbeck marble is still extracted from quarries first mentioned in 1250.

SWANSEA, Welsh *Abertawe,* a municipal, county and parliamentary borough and seaport of Glamorganshire, Wales, at the mouth of the river Tawe on the north side of Swansea bay. Pop. (1961) 166,740. Area 33.8 sq.mi.

The *Via Julia* from Nidum (Neath) to Loughor probably passed through the north of the borough, where Roman coins were found in 1835. The name Swansea stands for Sweyn's "ey" or inlet, and may have been derived from Sweyn Forkbeard, who certainly visited the Bristol channel. The earliest known form of the name is Sweynesse, which occurs in a charter granted by William, earl of Warwick, some time previous to 1184; in King John's charter (1215) it appears as Sweyneshe, and in the town seal, of medieval origin, it is given as "Sweyse." The Welsh name, Aber Tawy, first appears in Welsh poems of the beginning of the 13th century. The town grew up round the castle which Henry de Newburgh (or Beaumont) built in the early 12th century on the west bank of the Tawe. (*See* GOWER.) In the Great Rebellion the town was royalist until the autumn of 1645 when Colonel Philip Jones was made its governor. The older part of the town, being the whole of the municipal borough previous to 1836, occupies the west bank of the Tawe near its mouth and is now wholly given up to business. Stretching inland to the north along the river for some 6 mi. through Landore to Morriston, and also eastward along the sea margin toward Neath, is the industrial quarter, while the residential part occupies the sea front and the slopes of the Town hill (573 ft. high) to the west, stretching out to Sketty. The attractive seaside resort of the Mumbles or Oystermouth and a large part of the Swansea rural district were included in the borough in 1918. The east side of the river is known as St. Thomas and Port Tennant.

The 12th-century castle has entirely disappeared; but portions of the new castle, which was probably intended only as a fortified house, are incorporated in the buildings of the town. The remains include a tower, a so-called keep with the curtain wall connecting them, and a fine embattled parapet with an arcade of pointed arches in a style similar to that of the episcopal palaces of St. David's and Lamphey built by Henry Gower (d. 1347), bishop of St. David's, to whom the building of the new "castle" is also ascribed. Traces of St. David's hospital, built by the same prelate in 1331, are still to be seen at Cross Keys inn. The parish church of St. Mary was entirely rebuilt in 1896–98, only to be destroyed in 1941 by an air raid. Little now remains of the earlier work. Within the parish of St. Mary was St. John's, a church once owned by the Knights Hospitallers. This church, which was entirely rebuilt in 1820, was renamed St. Matthew in 1880, when a new St. John's was built within its own parish. The Royal Institution of South Wales, founded in 1835, possesses a museum in which the geology, mineralogy, botany, prehistoric and later antiquities of the district are well represented. Its library is rich in historical and scientific works relating to Wales and Welsh industries. The free library and Glynn Vivian art gallery (opened 1911) contain exhibits of local and general Welsh interest. Near the shore at the west end of the town is the new guildhall, opened in 1934. It is notable as containing Frank Brangwyn's 16 panels depicting the peoples, flowers, fruits and animals of the empire, originally painted for the royal gallery of the house of lords as part of a peers' war memorial. The grammar school, founded in 1682 by Hugh Gore (1613–91), Bishop of Waterford, was destroyed during an air raid (1941); a new Bishop Gore school was opened in 1952. The University College of Swansea was founded in 1920. Beau Nash was born in Upper Goat street in 1674. The town has about 3,000 ac. of open spaces. De Braose's charter of 1306 gave the burgesses the right to take from the lord's woods sufficient timber to make four great ships at a time and as many small vessels as they wished. Coal was even then worked in the district. Cromwell in his charter of 1655 recognized Swansea as "convenient for shipping and resisting foreign invasions."

From about 1768 to 1850 Swansea had a famous pottery. Beginning with earthenware which twenty years later was improved into "opaque china," it produced from 1814 to 1823 superior, beautifully decorated porcelain.

During the 18th century coal began to be worked at Llansamlet and copper smelting (begun at Swansea in 1717, though at Neath it dated from 1584) assumed large proportions. The coal was conveyed on the backs of mules and later by means of a private canal. Under an act of 1791 harbour trustees cleared the river bed and built a long pier on either side of it. A canal connecting the tidal part of the river Neath with the mouth of the Tawe was made in 1789, and also a small dock, Port Tennant or Salthouse dock, near the east pier, which continued to be used till 1875. Meanwhile in 1798 the entire coal-producing Swansea valley had been connected with the port by a canal 16½ mi. long (acquired by the Great Western railway in 1872). In 1845 the river was diverted eastward into a new channel (called the New Cut) and its old channel was locked and floated in 1852, thereby forming the North dock. (Area 11½ ac., and a half tide basin 2½ ac. Length of quays 5,500 ft.) The South dock, begun in 1852 and opened in 1859, is mainly used for shipping coal and general cargo and for discharging timber and fish. It has an area of 18½ ac.; length of quays 6,550 ft.; depth of water in lock 34 ft.

The next development was on the east side of the river where the shore of Fabian's bay, inside the harbour mouth, was extended for the construction of the Prince of Wales dock (authorized 1874, opened Oct. 1881, and subsequently extended), area 28 ac.; length of quay 6,872 ft. The very rapid increase in the demand for anthracite coal (for the shipment of which Swansea has practically a monopoly) soon necessitated still further accommodation and in July 1904 was begun the King's dock, which lies farther east and has an entrance direct from the bay. By means of the embankment made in connection with it, 400 ac. were reclaimed from the sea. King's dock and basin is 221 ac.; depth of water 40 ft. (high tide); length of quays 14,050 ft. The Queen's dock, exclusively an oil dock, occupies 150 ac. There are three dry docks and the entire harbour has some 270 ac. of deep water, over 6 mi. of quays and 130 mi. of railway sidings. Imports include crude oil, copper, nickel, iron, timber, grain and rubber. Exports include coal, patent fuel, refined oil, coke, tin plate and large quantities of manufactured goods.

Formerly acknowledged as "the metallurgical capital of Wales," Swansea is still an important seat of the copper, tin plate and spelter or zinc industries. Three-fourths of the tin plate manufactured in Great Britain and a very high proportion of the spelter are made in the district. There are also important steel works, and light industries have been developed, notably on the Fforestfach trading estate. In 1918 Swansea became an important centre for the distribution of oil, extensive storage and refining facilities (since enormously extended) being opened at Llandarcy.

Administration.—The town claims to be a borough by prescription because (although its charter of creation cannot be found or established) its status may be inferred from King John's charter of 1215 in which the inhabitants are addressed as "our burgesses of Sweyneshe." Its first grant of municipal privileges may have been in the charter of William, 3rd earl of Warwick, granted some time before 1184. In 1208 King John granted Gower by charter to William de Braose whose descendant gave Swansea and Gower various liberties by a charter of 1306 (*see* above). These were confirmed by the earl of Worcester's charter in 1532. Cromwell's charter of 1655 changed the title of portreeve into mayor, but this lasted only until 1659 when the title of portreeve was resumed.

From 1535 to 1832 (with the exception of 1658–59) Swansea was one of several contributory boroughs sending only one member to parliament. In 1832 Swansea, with four other contributory boroughs known together as Swansea District, was again represented by one member. In 1885 the district was split into two divisions, Swansea Town and Swansea District, each returning one member. In 1919 a different division was made which still

remains: Swansea West and Swansea East.

The assizes and quarter sessions for the administrative county of Glamorgan are held at Swansea and Cardiff alternately, but the borough has its own separate commission of the peace and quarter sessions. It became a county borough in 1889 and in 1923 the Church in Wales created a bishopric of Swansea and Brecon. In Feb. 1941 the whole business centre of the town (about 25 ac.) was destroyed by air raids.

SWARAJIST. The term *swaraj* (more properly *swarajya* from *swa*=own or self; *rajya*=rule or government) was originally employed in the ethical sense of control over self—self mastery. Prominence was first given to it in the political arena by Dadabhai Naoroji, who, in his presidential address to the Indian national congress in Calcutta in Dec. 1906 claimed as the right of India *swaraj* "or self government like that of the United Kingdom or the Colonies," and the word soon gained currency as the equivalent of dominion home rule. By a judicial decision of the Calcutta high court (1907, I.L.R., 34 Calc.), it was held not necessarily to mean "independent government" in the sense of government of the country to the exclusion of the present government. "It may mean, as is now well understood, government by the people themselves under the King and under British sovereignty." Its adoption as the label of a particular political party was the outcome of the lengthy and ever changing agitation set on foot by M. K. Gandhi in 1919. That movement commenced as one of passive resistance to the legislation known as the Rowlatt act, which was designed to strengthen the hands of the government in dealing with revolutionary crime, but, utilizing the resentment aroused among Mohammedans by the Turkish peace terms, which crystallized in the Khilafat movement, and the excitement which ran through the country as the result of disturbances in the Punjab and their sequelae, Gandhi, in the succeeding year, launched a campaign of protest under the guise of nonviolent nonco-operation, which was to include the boycott of the courts and government schools, the resignation of titles and government office, and abstention from participation in the forthcoming elections to the new legislative councils under the Reforms scheme.

In July 1920 the attainment of *swaraj* was included among the objects of the nonco-operation movement, and at the meeting of that year it was adopted by the Indian national congress as their avowed aim. But as to the precise meaning of *swaraj* there existed a vagueness which Gandhi did little to dispel. At one time he defined it as parliamentary government, whether within or without the empire; at another as dominion home rule; at a third as the universal employment of the spinning wheel; yet again as the triumph of the Khilafat party. On the other hand, at the first meeting of the legislative assembly in Feb. 1921, in the message from His Majesty the King Emperor, the ideal of *swaraj* was mentioned as the dream for years of patriotic and loyal Indians, while the reforms were cited as the beginnings of *swaraj* within the empire.

In the first elections under the 1919 act Gandhi's followers took no part, but an influential section of the congress, acting under the leadership of C. R. Das and Pandit Motilal Nehru, announced on Jan. 1, 1923, the formation of a Congress Khilafat Swarajya party, in whose program the capture of the councils and the obstruction of all business in them was the leading immediate item. After protracted dissensions and maneuvers this section was finally victorious within the congress, and at the elections of Nov. 1923 Swarajist candidates took the field as such and, noticeably as against the Moderates, achieved considerable success, though failing to secure (except in one province) the clear majority for which they had hoped. Throughout the term of the second reformed councils the Swaraj party continued their wrecking tactics, succeeding in two provinces (Bengal and the Central Provinces) in bringing about a temporary suspension of the reformed constitution.

Toward the end of that year the party was split by the defections of some of its members, notably in Bombay and the Central Provinces, in the direction of "responsive co-operation," including the acceptance of office under government, and in April 1926 an attempt was made to form an Indian national party of responsivists, independents and moderates "to prepare for and accelerate the establishment of *swaraj* or full responsible government in India, such as obtains in the self-governing dominions of the British empire." These differences bore fruit at the third election of the reformed councils at the end of 1926, when the Swaraj party definitely lost ground, noticeably in the assembly and in the United Provinces, Punjab and Central Provinces. The Indian national congress (which by that time was practically the Swaraj party) in Dec. 1927 declared for the complete independence of India.

SWARTHMORE, a borough of Pennsylvania, U.S., is a residential suburb of Philadelphia, located in Delaware county, about 11 mi. S.W. of the city. The population of less than 5,000 is composed principally of the families of commuters to offices in Philadelphia and Chester. The community grew up around Swarthmore college, a coeducational institution founded in 1864 by the Hicksite body of the Society of Friends and since 1911 nonsectarian. It is noted principally for its system of honours courses initiated in 1921 by Frank Aydelotte (1880–1956), president of the college from 1921 to 1940. Those who qualify for this program participate in honours reading and research seminars in three chosen fields of concentration during their junior and senior years. On the campus is the two-and-one-half story gray stone house in which the artist Benjamin West was born. It was built in 1724 in the characteristic Philadelphia style of that era.

For comparative population figures *see* table in PENNSYLVANIA: *Population.* (R. F. WE.)

SWASTIKA, a decorative and symbolic ornament consisting of a cross with equal arms, to the end of each of which is attached a line running at right angles to it, all these extensions occurring on the same relative side, so that all four extensions have the same rotary direction in relation to the centre. The swastika is one of the most ancient and widespread of all ornamental forms, appearing in both hemispheres. It is generally interpreted as a sun symbol. The swastika occurs in Aegean and archaic Greek pottery and in certain types of fret, found in Egypt and Greece. In some examples it appears as two identical S-curves, intersecting in the middle and set at right angles. Occasionally three arms are found, and the heraldic symbol of three running legs set radially, may be a development. Adolf Hitler made the swastika Germany's national symbol. (T. F. H.)

SWAT, a semi-independent state in the Peshawar division of West Pakistan adjoining the Mardan district, consisting of the valley of the Swat river above its confluence with the Panjkora, which is reached by the Malakand, the Shahkot and other passes from the south. It is divided into two distinct parts: Swat-Kohistan or mountain country, on the upper reaches of the Swat and the Swat proper lower down. The state has an area of 2,934 sq.mi. and a population (1951) of 518,596.

The Swat river (Sanskrit *Suvatu;* Greek *Suatos*) is formed by the junction of the Gabral and Ushu in the Kohistan at Kalam. The united stream sweeps in a great curve southwestward to Abazai, where it emerges to the north of Mohmand hill into the Peshawar plain. The river is utilized by canals to irrigate about 160,000 ac. The valley, which is very narrow in the higher mountains, contains a series of rich fertile tracts in the Swat proper and these are extensively cultivated. There are vast forests of deodar in the Kohistan region.

The Yousufzais (or Afghans) who form the largest group of the population are mainly concentrated in the lower valley while the Kohistan is peopled by Torwais and Garhwis. The state is known for its good administration in a traditionally turbulent area. Saidu Sharif, the capital, is 28 mi. from Malakand and is connected with it by a good motor road. Swat acceded to Pakistan soon after the partition of India and some of the powers of the ruler have been transferred to a partly elected, partly nominated council. In 1954 the administration of the adjacent territory of Kalam (area 822 sq.mi., pop. [1951] 9,702) was also entrusted to Swat.

Swat has great historic interest as a region bordering on Europe and Asia; it was one of the conquests of Alexander the Great and was also a remarkable stronghold of the Buddhist faith. It is recorded by Chinese pilgrims that in the 5th, 6th and 7th centuries there were as many as 1,400 monasteries in the region.

Excavations were begun in 1956 by the Italian Archaeological mission. At Mingora an important monastery has been found and at Udegram the mission has unearthed rock carvings which are probably prehistoric, part of the lower town and an immense staircase 25 ft. wide leading up from the valley to the mass of a castle, plans for the excavation of which were announced.

(K. S. Ad.)

SWATOW (also Shan'tow), a port in the province of Kwangtung, China, at the mouth of the main branch of the Han river. The population in 1953 was estimated at 200,000. Swatow was formerly a small fishing village, and the present town was built to a large extent on reclaimed land. English merchants settled on Double Island, in the river, as early as 1856 and began trading. Swatow is a great emigration port and was the scene of many kidnapping adventures on the part of foreigners in the early days. The region retained a full tribal organization until the latter half of the 19th century. Serious difficulties arose with the T'aip'ing rebellion and foreign interferences.

The city is the outlet for Chao-chow, about 30 mi. up the river, and the centre of a sugar cane district. Bean cake is manufactured and was also imported from Niuchwang, Shanghai and Hong Kong. Among usual leading exports are tea (after about 1872), sugar and oranges, paper, tobacco, grass cloth (manufactured at Swatow from the so-called Taiwan hemp), lace, drawn thread work embroidery. The imports ordinarily include cereals, peas, beans, kerosene oil and piece goods. The port was opened to foreign trade in 1869. The town, situated at the southern end of Formosa strait, is exposed to fierce typhoons. The Japanese occupied Swatow in 1939.

SWAYTHLING, SAMUEL MONTAGU, 1st Baron (1832–1911), British financier, was born at Liverpool on Dec. 21, 1832, of a Jewish family named Samuel. He took by royal licence the name of Montagu. He rose to be the head of the most important arbitrage house in London. He was Liberal M.P. for the Tower Hamlets from 1885 to 1900; he was a member of the Gold and Silver commission of 1887–90, being himself a bimetallist. He was created a baronet in 1894 and raised to the peerage in 1907. He was a zealous promoter of Jewish interests, founding the loan fund of the Jewish board of guardians, the Jewish workingmen's club and several synagogues.

Lord Swaythling succeeded Sir Julian Goldsmid as chairman of the Russo-Jewish committee, and also helped to establish a modern secular school for Jews at Jerusalem (1875). He died on Jan. 12, 1911, in London. His son, E. S. Montagu, was secretary for India.

SWAZI. The Swazi are an African tribe of the Embo-Nguni group of Bantu people. They speak a language closely allied to Zulu and Xosa. The political system consists of a hereditary paramount chief (*Ngwenyama*) who is the central figure of the tribe in political, social, military, religious and economic affairs. His mother (*Ndlovukati*) occupies a unique position and must be consulted in all tribal affairs. The *Ngwenyama* is advised by a small privy council (*liqoqo*) and by a general council (*libandla*) consisting of all chiefs and important men of the tribe. Any adult male, however, is entitled to attend and take part in its proceedings. Local government is in the hands of chiefs whose office is also hereditary. Each has a *liqoqo* and a *libandla* composed of his followers. The Swazi are horticulturists and have a culture which attaches considerable economic and ritual value to cattle.

(B. A. M.)

SWAZILAND, British protectorate in southern Africa, administered by the high commissioner for Basutoland, the Bechuanaland protectorate and Swaziland. It is a compact country of 6,704 sq.mi. surrounded on three sides by the Union of South Africa and on the east hemmed in from the sea by Portuguese East Africa, or Mozambique.

Physical Geography.—The territory consists of three fairly well-defined regions of about equal breadth running from north to south. The mountainous high country to the west is a spur of the Drakensberg which reaches altitudes of over 6,000 ft. The average rainfall in this region is 55.6 in. although it varies considerably from year to year and from place to place. This region provides good winter pasturage for sheep and is suitable for afforestation. The middle veld to the east is characterized by wide valleys with less rainfall (average about 36 in.) but suitable for mixed farming. There the tributaries which flow down steep gorges join to form the main river system which drains the territory into the Indian ocean. These rivers, the Komati, the Mbuluzi, the Usutu and the Ngwavuma, traverse the Lubombo flats which comprise the low country, the only considerable area of fairly level ground lying about 500 ft. above sea level and consisting of fertile soil with savannah type vegetation and good pastures. The rainfall is low (average about 20 in.) and badly distributed. The main rivers on their course eastward to the sea in Portuguese territory cut through the Lubombo range.

History.—According to their traditions the Swazi lived originally in southern Tongaland on the southeastern littoral of South Africa whence they migrated at the beginning of the 19th century to Shiselweni; *i.e.*, the country to the west of the Lubombo range between the Pongolo and Great Usutu rivers. There they remained until 1815 when, being attacked by the Ndwandwe chief, Zwide, the main portion of the tribe under their chief Somhlolo, otherwise Sobhuza I, fled northward to the present site under the Mdzimba mountain near Bremersdorp. Under Somhlolo's successor Mswazi, who gave his name to the tribe, they occupied considerable areas in what is now a portion of the Union of South Africa, and conquered and assimilated petty tribes or clans of Sotho origin. After their flight from Zwide the Swazi were occasionally raided by the Zulu and themselves made forays into neighbouring territory. Mswazi made an abortive attempt to check the depredations of the Zulu by seeking the protection of Queen Victoria through Theophilus (later Sir Theophilus) Shepstone.

More formal relations with Europeans were established with the signing of a treaty by Somcuba on behalf of Mswazi in July 1846 which purported to grant to *de Hollandsche Zuid Afrikaansche Natie* a large portion of territory included in the modern districts of Lydenburg, Middelburg, Barberton and Carolina in the Transvaal. In 1864 the Swazi assisted the Boers in a campaign against their traditional enemy Mapoko (Mapoch) and in 1880 assisted the British against Sekukuni, chief of the Bapedi.

By 1878 white settlers and prospectors had established themselves in considerable numbers in Swaziland, attracted by the fertile and well-watered terrain abounding in game and rich in the promise of minerals. They secured concessions over land, minerals and grazing as well as to exemptions from taxes, to railways, to telegraphs, to mining patents, collection of the revenue and trading.

In 1888 a charter of self-government was granted to the Europeans, and two years later, under a convention between the British government and the South African Republic of the Transvaal, a provisional government, consisting of representatives of the two powers and a representative of the Swazi, was set up with the consent of the latter. Three years later the provisional administration came to an end when the British government signed a new convention permitting the South African republic to acquire from the Swazi regent and her council an organic proclamation conferring on the republic rights of jurisdiction, legislation and administration without incorporation into the republic. The Swazi refused to sign the proclamation, but its provisions with some of those in the 1893 convention were embodied in the final convention of 1894 under which the South African republic exercised powers of protection, legislation, jurisdiction and administration in Swaziland subject to the limitations of the convention. After the conquest of the Transvaal all the rights and powers of the republic passed to Great Britain, and an order in council under the Foreign Jurisdiction act was issued in June 1903 providing that the governor of the Transvaal should administer Swaziland and conferring on him the right to legislate by proclamation. In 1906 these powers were given to the high commissioner. The main task of this administration was to settle the concessions question, which was achieved in 1907 by the issue of a proclamation under which land and grazing concessions suffered a deduction of one-third of their area for the exclusive use and occupation of the Swazi.

Population.—The population in 1956 was 237,041, an increase of 28.0% since 1946. The European population, which

in 1921 was 2,205, had risen to 5,932 in 1956, and in the same period the coloured or mixed population rose from 451 to 1,391. There are European villages at Mbabane, the administrative capital, and Bremersdorp, with European populations of between 800 and 1,000, and there are smaller villages at Emlembe, Piggs Peak, Goedgegun, Hlatikulu, Mankaiana and Stegi.

Religion.—Apart from indigenous religions, Christianity alone is represented by 23 denominations.

Education.—There were, in 1958, six government primary schools for Europeans, two government secondary schools and one other secondary school run by a voluntary agency. The total enrollment of European children in 1958 was over 1,000. Schools for Africans fall into the following groups: 95 unaided mission schools, 115 aided mission schools, 37 tribal schools, 3 national schools and 17 government-maintained schools. Total enrollment in 1957 was 26,589 pupils. In addition there are a teacher training school, a trades school and a nursing school. There were 4 mission schools for coloured children, of which 3 were government aided; the total enrollment in 1957 was 418.

There are three government and three mission hospitals in the territory (all of the latter are government aided) and two company hospitals treating employees only. There are also seven government health centres and one government cottage hospital.

Administration.—In the United Kingdom, responsibility for the administration of the territory rests with the secretary of state for commonwealth relations. A high commissioner has powers under the order in council of 1906 to administer and legislate for the territory, and he has similar powers in respect of Basutoland and the Bechuanaland protectorate. He resides, however, in the Union of South Africa, where he is also high commissioner for the government of the United Kingdom.

In Swaziland and directly responsible for its administration is a resident commissioner, who governs subject to the directions of the high commissioner under powers vested in him by proclamation and by his commission. He has a staff of administrative, technical and subordinate officials, and, in respect of European affairs, is assisted by an advisory council, first established in 1921, of ten elected Europeans. A system of administration was set up in 1950 by proclamation which provided for the administration of the Swazi by their paramount and other chiefs together with their councils in close conformity with traditional law and custom. A system of native courts was also established exercising criminal as well as civil jurisdiction over Africans.

Agriculture and Exports.—The principal occupation of the inhabitants, African and European, is agriculture, but many are also employed in mining, trading, building and forestry projects as well as by the government on public works, and in agricultural and veterinary services. Whereas the mining industry in Swaziland absorbs about 150 Europeans and 2,600 Africans, there are about 7,000 Swazi employed in the Union of South Africa, principally in gold and coal mines.

Of the 4,279,655 arable acres in the territory, 2,250,520 ac. are available for occupation by the Swazi; viz., 35 separate blocks of "native area" set aside for their sole and exclusive use and occupation, 240,000 ac. purchased by the Swazi nation from European landowners, 363,865 ac. of crown land and land purchased by the government for a Native Land Settlement scheme, and 12,883 ac. purchased by individual Africans. The remainder, apart from a few acres of crown land, is owned by Europeans who derive their title from concessions granted at the end of the 19th century by the then paramount chief Mbandeni.

Livestock raising is practised by Europeans and nearly all Swazi. The largest number of cattle (355,659 in 1957) are owned by Africans, but the number owned by others rose steadily during the 1950s, reaching 107,360 in 1957.

The staple diet of the Swazi is maize. They also grow sorghums which are usually converted into beer. Other crops are peanuts, sugar, tobacco, beans and rice. Tung trees do well, as do citrus, avocados, pineapples and other subtropical fruits.

The principal exports are asbestos, live cattle, cotton, hides and skins, butter, metallic tin and patulite (hard board). Gold is mined on a small scale and some barytes is produced. There are large unexploited coal fields in the low veld and rich iron deposits in the high veld.

Communication.—There are no railways in the territory, but 510 mi. of bus services are operated by the South African Railways administration.

Finance.—The main heads of taxation are income tax (levied on non-Africans only); customs and excise (under an agreement with the Union of South Africa, Swaziland receives a 0.149% share of the total collection of the Union); native tax; and base metal royalties (chiefly from asbestos production). The total ordinary revenue rose from £479,899 (1950–51) to £1,207,540 (1956–57). Similarly, expenditure increased from £559,410 (1950–51) to £1,052,374 (1956–57). £366,348 was received from colonial development and welfare funds in 1956–57.

A Swazi national treasury was established to handle the finances of the newly created native administration in 1950.

SWEARING. The common use of the word is for the uttering of profane oaths or curses. In English law, while blasphemy (*q.v.*) was at common law an indictable offense, cursing or swearing was left to the ecclesiastical courts. The Profane Oaths act, 1745, inflicted a sliding scale of fines for the use of profane oaths according to the rank of the offender: 1*s.* for a common labourer, soldier or seaman, 2*s.* for everyone below the rank of gentleman and 5*s.* for those of or above that rank; procedure under this act is regulated by the Summary Jurisdiction acts. By the Town Police Clauses act, 1847, the use of profane or obscene language is an offense punishable on summary conviction by a fine not exceeding 40*s.* or imprisonment not exceeding 14 days. The offense must be committed in a street. In the United States, blasphemy is a crime under either the common law or the statutes of substantially all of the states.

SWEATER, a jacket or short coat of a woollen material, usually knitted, and sometimes called a jersey, because it was worn by the sailors of the Island of Jersey. The first sweaters were heavy, dark-blue jackets, which were pulled on over the head, and were worn by the participants in athletic contests before and after games, to prevent cold.

SWEATING SICKNESS. A remarkable form of disease not known in England before, it attracted attention at the beginning of the reign of Henry VII. It was known indeed a few days after the landing of Henry at Milford Haven on Aug. 7, 1485, as there is clear evidence of its being spoken of before the battle of Bosworth on Aug. 22. Soon after the arrival of Henry in London on Aug. 28 it broke out in the capital and caused great mortality. This alarming malady soon became known as the sweating sickness. It was regarded as being quite distinct from the plague, the pestilential fever or other epidemics previously known, not only by the special symptom which gave it its name, but also by its extremely rapid and fatal course.

After 1485 nothing more was heard of it until 1507, when the second outbreak occurred, which was much less fatal than the first. In 1517 there was a third and much more severe epidemic. In Oxford and Cambridge it was very fatal, as well as in other towns, where in some cases half the population were said to have perished. There was evidence that the disease had spread to Calais and Antwerp, but with these exceptions it was confined to England.

In 1528 the disease recurred for the fourth time and with great severity. It first showed itself in London at the end of May, and speedily spread over the whole of England, though not into Scotland or Ireland. In London the mortality was very great; the court was broken up, and Henry VIII left London, frequently changing his residence. The most remarkable fact about this epidemic is that it spread over the continent, suddenly appearing at Hamburg, and spreading so rapidly that in a few weeks more than a thousand persons died. Thus was the terrible sweating sickness started on a destructive course, during which it caused fearful mortality throughout eastern Europe. France, Italy and the southern countries were spared. It spread much in the same way as cholera,

passing, in one direction, from north to south, arriving at Switzerland in December, in another northward to Denmark, Sweden and Norway, also eastward to Lithuania, Poland and Russia, and westward to Flanders and Holland, unless indeed the epidemic, which appeared simultaneously at Antwerp and Amsterdam on the morning of Sept. 28, came from England direct. In each place which it affected it prevailed for a short time only—generally not more than a fortnight. By the end of the year it had entirely disappeared, except in eastern Switzerland, where it lingered into the next year; and the terrible "English sweat" has never appeared again, at least in the same form, on the continent.

England was, however, destined to suffer from one more outbreak of the disease, which occurred in 1551, and with regard to this we have the advantage of an account by an eyewitness, the physician John Kaye or Caius.

The disease began suddenly with a sense of apprehension, followed by cold shivers (sometimes very violent), giddiness, headache and severe pains in the neck, shoulders and limbs, with great prostration. After the cold stage, which might last from half-an-hour to three hours, followed the stage of heat and sweating. The characteristic sweat broke out suddenly, and, as it seemed to those accustomed to the disease, without any obvious cause. With the sweat, or after that was poured out, came a sense of heat, and with this headache and delirium, rapid pulse and intense thirst. Palpitation and pain in the heart were frequent symptoms. No eruption of any kind on the skin was generally observed; Caius makes no allusion to such a symptom. In the later stages there was either general prostration and collapse, or an irresistible tendency to sleep, which was thought to be fatal if the patient were permitted to give way to it. The malady was remarkably rapid in its course, being sometimes fatal even in two or three hours, and some patients died in less than that time. Those who survived for 24 hours were considered safe.

The disease, unlike the plague, was not especially fatal to the poor, but rather, as Caius affirmed, attacked the richer sort and those who were free livers according to the custom of England in those days. "They which had this sweat sore with peril of death were either men of wealth, ease or welfare, or of the poorer sort, such as were idle persons, good ale drinkers and taverne haunters."

Causes.—Some attributed the disease to the English climate, its moisture and its fogs, or to the intemperate habits of the English people, and to the frightful want of cleanliness in their houses and surroundings which was noticed by Erasmus in a well-known passage, and about which Caius was equally explicit. But it must be concluded that climate, season and manner of life were not adequate, either separately or collectively, to produce the disease, though each may have acted sometimes as a predisposing cause. The sweating sickness was in fact, to use modern language, a specific infective disease in the same sense as plague, typhus, scarlet fever or malaria.

The only modern disease resembling sweating sickness is that known as *miliary fever* ("Schweissfriesel," "suette miliaire" or the "Picardy sweat"), a malady which has been observed in France, Italy and southern Germany, but not in the United Kingdom. It occurs in limited epidemics, not lasting more than a week or two (at least in an intense form). The attack lasts longer than the sweating sickness, is accompanied by eruption of vesicles and is not usually fatal. The first clearly described epidemic was in 1718 (though probably it existed before) and the last in 1861. Between these dates about 175 epidemics have been counted in France alone.

BIBLIOGRAPHY.—For history *see* Bacon's *Life of Henry VII*, and the chronicles of Grafton, Holinshed, Baker, Fabyan, etc. The only English medical account is that of John Caius, who wrote in English *A Boke or Counseill Against the Disease Commonly Called the Sweate, or Sweating Sickness* (London, 1552); and in Latin *De ephemera britannica* (Louvain, 1556; reprinted London, 1721). The English tract is reprinted in Babington's translation of Hecker's *Epidemics of the Middle Ages* (Syd. Soc., 1844). This also contains Hecker's valuable treatise on the English sweat, published in German (1834), and also printed in his *Volkskrankheiten des Mittelalters*, edited by Hirsch (Berlin, 1865). Grüner's *Scriptores de sudore anglico* (Jena, 1847) contains nearly all the original documents, including the two treatises of Caius. *See* also Hirsch, *Handbook of Geographical and Historical Pathology*, trans. by Creighton (New Syd. Soc., 1885).

SWEATING SYSTEM, a term used to describe oppressive industrial conditions in certain trades. The word sweater was used in England as early as 1850 to describe an employer or middleman who exacted monotonous work at very low wages. Charles Kingsley in his novel *Alton Locke* (1850) and his political pamphlets directed attention to London "sweaters"; and Henry Mayhew in 1851 talked of "the sweating system."

The system can be traced in certain trades in most countries both inside and outside Europe. It is closely associated with contracting. Individual workers or groups of workers contract to do a certain job for a certain price. Sometimes they carry out this contract themselves; in other cases they let it out again to subcontractors at lower prices. Contracting makes possible labour exploitation, often of women and children; and it produces erratic employment. When trade is brisk extremely long hours are worked in seriously overcrowded workrooms or dwelling houses. When trade is slack, subcontractors, whose overhead costs are far lower than those of factory employers, dismiss workers without scruple. One of the earliest objectives of factory and minimum-wage legislation is to eliminate such exploitation.

Contracting and subcontracting are common in the garment manufacturing industry. In the 19th century outwork existed in other industries, such as boot-and-shoe manufacture and soapmaking. Although legislation had by the middle of the 20th century either eliminated or carefully controlled sweating in most highly developed countries, the system was still operating in many Asiatic countries where larger numbers of people were engaged in home work than in industrial establishments.

Conditions tend to be worse in large cities, where sweatshops are hidden away in slum areas. They are aggravated by influxes of cheap labour from outside. To the native poor engaged in tailoring in London in the 1880s was added a large immigrant labour force of unskilled foreigners. In the United States the tireless search for cheap labour encouraged such immigration until 1917.

The first large-scale official inquiry into the sweating system was carried out by a select committee of the house of lords in England. Its report, published in 1890, described conditions in tailoring, bootmaking, furriery, shirt making, mantle making, cabinetmaking, cutlery and hardware manufacture, chainmaking and nail making, saddlery and harness making, military accoutrement establishments and dock labour. It claimed that sweating involved: (1) a rate of wages inadequate in terms of work done or basic standard of living; (2) excessive hours of labour; and (3) insanitary conditions in the houses or workshops in the houses in which the work was carried on.

The inquiry of the select committee did not bear fruit immediately. It was not until 1909 that the Trade Boards act set up boards to fix minimum wages in specified industries such as machine-made lace manufacture and chainmaking. In 1918 the scope of the act was extended to cover any trade where the ministry of labour considered that machinery for the effective regulation of wages was inadequate. Government interference was important, chiefly because it permitted the development of collective bargaining. By 1939, though many workers still received low wages, there were no longer any sweated trades in Great Britain.

In the United States most of the pressure to eliminate sweating was applied by organized labour. A number of acts, culminating in 1882, prohibited Chinese immigration. The first minimum-wage law was passed in Massachusetts in 1912. Numerous state laws improving factory and outwork conditions followed; and by 1939 practically all states had limited the hours of labour for women, and several had introduced legislation prohibiting night work.

Four main factors contributed in other countries as well as in Great Britain and in the United States to the control of sweated industries: (1) social idealism; (2) the pressure of trade unions; (3) the extension of the franchise and the growth of labour parties; and (4) the growing economies of factory production and the increased interest in human relations in industry. In 1928 the International Labour organization carried a recommendation concerning minimum-wage fixing that gave home workers and others subject to contracting and subcontracting some measure of protec-

tion; and further action was mooted after World War II.
(A. BRI.)

UNITED STATES

The sweating system grew in the United States during the Civil War, when soldiers' wives were employed to make uniforms with the relatively newly developed sewing machines. Its advance was slow, however, until the 1880s, when immigrants from eastern and southern Europe provided a large source of cheap labour. At that time the conditions necessary for a sweating system existed: a mass of unskilled, unorganized poverty-stricken men, women and children incapable of resisting the economic pressure to compete for work—women against their husbands, children against their parents; power-using factories or shops, where materials could be prepared for simple processes done in smaller shops or in the homes of workers or both; and mechanized transportation to and from the sweatshops and tenement dwellings, eliminating the long journeys on foot by heavily laden men, women and children. Motor trucks and the parcel post contributed to widen enormously the area within which the sweating system could be carried on.

As the first simple foot-powered sewing machines brought the sweating system to the soldiers' families, so the ceaseless evolution of the power-driven machines, first steam, later electric, served to concentrate the production of garments in vast skyscrapers near railway stations to which the employees travelled from their widely dispersed homes. That concentration facilitated labour organization within the garment industry.

Sweating-system evils also prevailed in other U.S. industries based on small workshops, homework and cheap labour, such as the making of cigars and artificial flowers. Inside and outside the garment industry the unions strove ceaselessly against sweating. In 1889 the tobacco workers obtained the passage of a New York statute forbidding all manufacture of tobacco in any tenement house, but it was held unconstitutional by the New York court of appeals and homework was prolonged for a number of years. The U.S. department of labour and various organizations, such as the National Consumers' league, also participated in the movement against the sweating system, and by the 1930s the conditions which had made it possible in the clothing industry had been virtually eliminated.

Beginning in 1912 in Massachusetts, a number of states passed laws creating minimum wage boards or commissions. The U.S. supreme court, however, in *Adkins* v. *Children's Hospital* (261 U.S. 525, 1923) held that a U.S. statute authorizing a wage board in the District of Columbia to fix minimum wages of women and minors violated the guarantees of the due process clause of the fifth amendment of the U.S. constitution, since freedom to contract between the employer and employee was impaired. The Adkins decision was reversed by the court in 1937 in the *West Coast Hotel Co.* v. *Parrish* (300 U.S. 379) decision. Many states passed minimum wage laws, and in 1938 a Federal Fair Labor Standards act covering industries engaged in interstate commerce was enacted.
(F. KE.; X.)

SWEDEN (SVERIGE), a kingdom of northern Europe, occupying a part of the Scandinavian peninsula. The length is about 990 mi., the extreme breadth (mainland) about 250 mi. and the total area, inclusive of inland waters, of which the four great southern lakes comprise 3,522 sq.mi., is 173,665 sq.mi. The boundary is estimated at 6,100 mi.; 4,737 mi. are coastal, the Norwegian frontier is 1,030 mi. and the Finnish 333 mi.

Physical Features.—The backbone of Sweden is an ancient mountain range of which the crest line forms the Norwegian boundary. The three main territorial divisions of Sweden are Norrland, Svealand and Gotaland. The country may be described in four main physical divisions: the northern mountains and lake region district, covering all Norrland and the western part of Svealand; the lowlands of central Sweden; the Smaland highlands, in the south and southeast; and the plains of Skane, occupying the extreme south of the peninsula. The first district is much the largest and highest and contains the finest scenery. The greatest heights lie along the boundary, and several exceed 6,000 ft. Kebnekaise (6,965 ft.) in northern Lapland, the highest point in Sweden, is a bold, somewhat isolated summit. Slightly south, beyond the Lule *alv*, is a lofty mass in which Sarektjakko (6,857 ft.), the second highest summit, is situated. Still farther south is the better-known Sulitelma (6,158 ft.); beyond is a progressive decrease in height southward until Areskutan (4,659 ft.) is reached. Near the southern flanks of Areskutan the railway from Trondheim, Nor., crosses into Sweden. South of the railway the highland line passes into Norway, but before doing so the mass rises into such heights as Helgasfjallet (5,892 ft.). There the snow line, which is about 3,000 ft. in the north, rises to 5,500 ft. The numerous rivers are linked with long, narrow, high-level (900–1,300 ft.) lakes, due mainly to dams of moraine. Among European countries only Finland exceeds Sweden in the number of its lakes. In Sweden the 96,000 lakes cover about 9% of the country, but the largest lie in the central lowlands. The northern rivers run through forests and enter the sea usually through long estuaries. The Torne, which, with its tributary the Muonio, forms the boundary with Finland, has a length of 354 mi. and drains Tornetrask (124 sq.mi.).

Along and near to the shores of the lake the railway from Gallivare runs to Narvik, Nor. The Kalix (267 mi.), with numerous rapids, is paralleled by the Lule, whose main stream is 279 mi. One of its branches, the Stora Lule, drains the Langasjaur and Luletrask, which together have a length exceeding 50 mi. but a total area of only 87 sq.mi. At the head of the Langasjaur is the Stora Sjofall (Great Lake falls; Lapp, Atna Muorki Kartje), 131 ft. In the southern mountain valleys of the region there are several beautiful falls, such as the Tannfors, not far from Areskutan. Still farther south of the Lule are the Pite river (230 mi.) and the Skellefte (255 mi.); the latter drains Horna *van* and Stora *van* (total area 163 sq.mi.). Horna *van* is a straight and sombre trough, but Stora *van* and the intervening Uddjaur are broad and picturesquely studded with numerous islets. The Ume (286 mi.) with its tributary the Vindel, of almost equal length, drains several lakes, including Stor Uman (63 sq.mi.). The further principal rivers of this region are the Angerman (279 mi.) with the magnificent Hallingsa fall within its drainage area, Indal (261 mi.) and Ljusnan (267 mi.). The Dal (323 mi.) embraces Lake Siljan (110 sq.mi.). The Klar has its upper waters—the Faemund—in Norway and reaches Lake Vanern after a course of 304 mi. The Torne has a drainage area of 15,521 sq.mi., but the Angerman has the largest basin (12,317 sq.mi.) of any river entirely in Sweden; the average for the other large northern streams is less than 8,000 sq.mi.

The lowlands resemble the coastal belt. There are fertile plains of clay, with innumerable lakes, including Vanern (Vener), Vattern (Vetter), Malar and Hjalmar, with areas respectively 2,141, 733, 440 and 190 sq.mi.; the Vanern is the largest lake in western Europe. The scenery of the lake district is quietly beautiful.

Granulite, also called eurite and halleflinta, is the most important of the Archaean formations and contains all the metalliferous deposits of Sweden. The rock is a very compact and fine-grained mixture of feldspar, quartz and mica, often grading into mica schist, quartzite and gneiss. The Cambrian and Ordovician strata occur in isolated patches. The deposits in most places are very little disturbed and form horizontal or slightly inclined layers. South of Vanern they are capped by thick beds of eruptive diabase. Conspicuous local features are the eskers or gravel ridges (*asar*), 100 to 200 ft. in height, in direction north-northwest. Their practical value lies in their excellent water supply and gravel.

South of the central lowlands the Smaland highlands lie in the heart of Gotaland and are a detached part of highland Sweden. They lie roughly south of Vattern and reach the southwest coast. The general elevation of this region exceeds 300 ft. and in the eastern part 600 ft.; the principal heights are Tomtebacken (1,237 ft.) and Galtasen (1,188 ft). There is much coniferous forest, but agriculture is profitable. The Smaland highlands abut southward upon the plains of Skane. Newer rocks of Cretaceous and Jurassic Ages, together with Recent marine deposits, have yielded level plains, with rich open meadows and cultivated lands, the monotony of which is in some parts relieved by beech woods. The Triassic formation (Rhaetic) in the northern part of Malmohus consists of

sandstones and clay beds with coal.

On the whole the rivers of south Sweden are few and short. Lake Vanern is drained to the Kattegat (Cattegat) by the short Gota river, on which, near the lake, are the celebrated falls of Trollhattan.

Coast.—The coast of Sweden, though not indented with so many or so deep fiords as that of Norway, yet resembles it in having a fringe of islands which, throughout large parts of its length, shelters the coast of the mainland from the open sea. This *skargard* is interrupted only round the southern shore off Skane.

The island belt is widest (45 mi.) off the city of Stockholm (noted for its beautiful sea approach). Farther north, only the narrow Alands Hav lies between the Swedish coast and the vast Aland archipelago, which extends to Finland. The *skargard* islands as a whole are rugged and picturesque; in the Baltic several are well wooded, but the majority, particularly in the Gulf of Bothnia, are bare or heath-clad. For the large islands Oland and Gotland *see* separate articles.

Climate.—Several factors contribute toward variations of climate in Sweden's several regions. The land runs through more than 13½° of latitude; about 15% of its area is within the Arctic circle; the boundary mountains are sufficiently high to be much colder than the adjacent coastal lands, but are not high enough to shut out entirely the warming effects of those drifts of wind and water from the southwest which give Norway its remarkable climate; the eastern and southern borders are washed by the sea; the piercing winter winds from the great Russian pool of cooled atmosphere can sweep westward over the Swedish lowlands or can reach the mountain tops which, on the whole, offer but moderate gradients for ascents. February is the coldest month and has a mean temperature of below 32° F. over Sweden. Stockholm averages 25.7°, Goteborg 30.4°, Haparanda 10.6°, but the coldest region is in the heart of Lapland; there the average for Karesuando is 5.2°. In some northern parts frost occurs in every month of the year, and at Karesuando only five months have a mean temperature above freezing point. July is generally the warmest month. Goteborg has a July mean of 62.2°, Stockholm 62°, Haparanda 59° and Karesuando 54.2°. The summer is short but high maximums are sometimes recorded; *e.g.*, 88° at Karasjok in Lapland.

The relative length of the seasons shows contrasts resembling those of temperature. At Karesuando the last day-frost of spring occurs on an average on June 15 and the first of autumn on Aug. 27, while at Stockholm four and a half months, and at Hven in the sound more than six months are frostless. Ice forms in October in the north and breaks up in May or June, while in the midlands and south the corresponding months are late November and April. The ice covering of the lakes ranges from 100 days annually in the south to around 200 days in the north, though local increases of the ice period occur in the upper Smaland highlands. Drifting sea ice generally appears in the Kattegat in January, but the sound becomes obstructed later largely by drift ice from the Baltic. In exceptional winters (*e.g.*, 1941, 1942) the sound may be completely frozen over. Ice conditions in the Baltic vary considerably from year to year but usually navigation in the southern part of the Gulf of Bothnia is impeded from the end of November to the beginning of May; in the north the gulf is covered with ice from November to mid-May, and among the islands it may linger until June.

The length of the Swedish summer day varies between wide limits. At Karesuando in 68° 26′ N. lat. the sun is continuously above the horizon from May 26 to July 18; at Haparanda it may be seen for 23 hours and at Lund for 17½ hours at the summer solstice. Refraction increases the average length of the day by 30 min. in the north and by 15 min. in the south. More important is the effect of twilight, which results in daylight's lasting without interruption from June 16 to 27 as far south as Harnosand (62° 38′ N.)

The average annual rainfall for Sweden increases, on the whole, from north to south, reaching a maximum toward the southwest. Thus the average in the north of Norrland is 16.5 in. and in the south it is 22.5 in. At Boras, midway between the south end of Lake Vattern and the Kattegat, the average is 35 in. The minimum at Karesuando is 12.3 in. The period of maximum is generally the latter half of the summer and the minimum February and March. The proportion of total precipitation which falls as snow ranges from 36% in Lapland to 9% in Skane. Snow lies 47 days on an average on the plains of Skane, while in the north it lies from 140 to 190 days. The Swedish glaciers cover about 135 sq.mi. They occur in the northern highlands about Kebnekaise, Sarektjakko and Sulitjelma. The most southerly is on the slopes of Helagsfjall in lat. 62° 54′ N.

Vegetation.—The extensive range of latitude and altitude produces many local vegetation differences. Four main regions can be distinguished, but they tend to grade into one another near their adjacent fringes. In descending order of altitude and, largely, of latitude also are: (1) alpine regions, (2) a zone of birch woods, (3) a coniferous forest region and (4) a beechwood region.

The alpine region occupies only the upper flanks of the spinal mountain range, at an altitude above 1,600 ft. in the north and above 3,000 ft. in the south. The lower belt of this region consists of thickets formed by several species of shrublike willows and dwarf birch, as well as of dwarf shrub communities and meadows. With increasing altitude the dwarf shrub communities, with species of *Cassiope* and crowberry, become more dominant and are accompanied by grass heath types. The vegetation of calcareous ground is much richer in species than that of siliceous ground and comprises Lapps' rhododendron, tree nymph (*Dryas*), arctic poppy (rare), several characteristic species of sedges, saxifrages, whitlow grasses, etc. The higher tops of the mountains are characterized by a few flowering plants scattered in carpets of mosses and lichens, alternating with almost or, at the highest altitudes, even entirely naked soil.

The birch forests are much more extensive in the north, where they form a subalpine belt, separating the coniferous forest region from the alpine region. The dominant tree is the birch *Betula tortuosa*, which grows together with rowan, bird cherry, some willows and aspen (which rarely attains tree size). The undergrowth is rich in herbs; *e.g.*, wood crane's-bill, globeflower, goldenrod, etc. In dry situations, on gravel, it is poorer; there lichens, especially reindeer "moss" and *Nephroma arctica*, are dominant.

The coniferous forests are the most extensive and cover nearly all the country northeast of Lake Vanern. The important tree on the drier and higher ground is the Scotch pine (*Pinus sylvestris*), with cowberry in the undergrowth. More fertile soils are occupied by spruce (*Picea abies*), having bilberry in the undergrowth. The conifers extend from sea level to 2,500 or 3,000 ft.; and though the pine and spruce predominate yet there is a sprinkling of lowland birches, rowans and aspen in the north, while large numbers of such deciduous trees as oaks, ash, limes, maples and elms are found in the south, especially on fertile soil. These latter trees seldom extend beyond 1,600 ft. above sea level, and the oak ceases about lat. 61° N. (inland) or lat. 63° N. (coastal).

The beech forests (with occasional oak) are restricted to Skane. They are tending to be reduced by extended land cultivation. The flowering plants of southern and middle Sweden are largely immigrants since the last glacial epoch, and the number of species shows a decrease northward. Many plants in northern Sweden are considered to be glacial survivors.

Fauna.—The effects of the great latitudinal range of Sweden are also shown in the case of fauna. Some animals, such as the hare, various shrews, the ermine, the weasel, the squirrel, the fox and the elk, are common to the entire country. Formerly bounties were paid for the extermination of the larger animals, which were thus greatly reduced in number. The bear is now protected and, with the wolf, glutton or wolverine and lynx, is becoming restricted to the more solitary depths of the northern forests. The wild reindeer is extinct, but large domesticated herds form practically the sole source of livelihood of the Lapps. The elk is the most valuable game animal, but badgers, which exist in large numbers in the midland plains, otters and the rare pine martens of the coniferous forests are hunted for their skins. The roe deer is spread over the southern and central parts of the country with a tendency to spread northward. The arctic fox and the lemming are mountain animals, the former being confined to the highlands of the north. When the lemmings make their nonperiodical migra-

tions to the lowlands their vast hordes are the prey of bird, wild and domesticated animals. The common porpoise is the only cetacean occurring in the Baltic, and with the gray seal it is held to be responsible for much damage to fisheries.

Bird life is very abundant, especially in spring and summer; several types such as the teal, snipe, golden plover and wagtail are found throughout the country. In the northern mountains the ptarmigan is common; ducks and other waterfowl frequent the lakes both there and in the south; the golden eagle, certain buzzards, owls and the small Lapland bunting are found. In the coniferous forests, grouse, capercailzie and woodcock have long been the principal game birds but are now less common; the crane lives in marshy clearings; birds of prey, crows and many other passerines range over a wide area. In the midlands partridges and doves are fairly common. On the coast large numbers of gulls and terns are found, also the eider duck and the rare sea eagle. There are very few reptiles or amphibians and the viper is the only poisonous species of snake. The rivers and lakes are generally well stocked with fish, such as salmon, trout, char, pike and perch. Both fresh-water and sea fisheries are important, especially on the west coast, where herring, cod, flatfish, mackerel and sprat are caught. Great numbers of a small herring called *stromming* are fished in the Baltic together with cod, eel, salmon and flatfish. In the brackish waters of the east coast salt-water and fresh-water forms are found. The crayfish occurs in many places in central and southern Sweden. Pearls are at times found in a fresh-water mussel, and oysters are cultivated to a small extent on the west coast. Among the lower marine animals a few types of arctic origin are found, not only in the Baltic but even in lakes Vanern and Vattern, having survived the changes consequent on the separation of the Baltic sea and the Arctic ocean.

Insect fauna is rich, even in the north. In summer in the northern lowlands the gadfly is common enough to cause annoyance to the reindeer, which it drives to the upper pastures and snow fields.

(W. E. Wh.; X.)

HISTORY

The first historical notice relating to Sweden is found in Tacitus, *Germania*, ch. 44, in which we find the name of the chief people of the peninsula, the Swedes proper, Suiones (Old Norse, Sviar; Swedish, Svear; Anglo-Saxon, Sweon), who eventually gave their name to the whole country. According to Tacitus they were governed by a king, whose power was absolute, and possessed a strong fleet which secured them from hostile incursions. Their original territories lay on both sides of Lake Malar, in the provinces later known as Uppland, Sodermanland and Vastmanland. Other early Roman writers, Mela and Pliny, mention the country. (*See* Scandinavian Civilization.)

The people next in importance to the Suiones in the peninsula (Swed., Gotar; O.N., Gautar; A.S., Geatas) are first mentioned by Ptolemy (under the form "Goutai" for Gautoi). He puts them in the southern part of the country. Gotaland consisted of Vastergotland and Ostergotland divided from one another by Lake Vattern, together with Smaland. In early times Vastergotland seems to have been the most important; Varmland, the district to the north of Lake Vanern, and the whole of the country to the north of Svealand seem to have been of small importance. Jamtland was always considered a part of Norway. After the time of Ptolemy we hear no more of Sweden until the 6th century, when a surprisingly full account of its peoples is given by the Gothic historian Jordanes. He speaks of trade in furs of arctic animals which were sold by merchant to merchant until they reached Rome.

For the same period information is to be found in the Anglo-Saxon poem *Beowulf*. The hero himself belonged to the Geatas (*i.e.*, in all probability, Gotar), his mother being the daughter of their king Hrethel. Haethcyn, Hrethel's son, is said to have perished in a disastrous battle against the Svear, but his fall was avenged by his brother Hygelac in a subsequent engagement in which the Swedish king Ongentheow was killed. This Hygelac is clearly identical with that Chochilaicus wrongly described as a Danish king by Gregory of Tours (iii, 3) who died in battle with the Franks under Theodberht about A.D. 520. About the time of Hygelac's death strife broke out in the royal family of the Svear, between Onela, the son and successor of Ongentheow, and Eanmund and Eadgils, the sons of his brother Ohthere. The latter fled for protection to the Gotar and the war which ensued cost the lives of Eanmund and of Heardred, the son and successor of Hygelac. According to the poem, Beowulf himself became king of the Gotar, but Beowulf's later history has a mythical character, and for three centuries after this time there is no reference to Swedish affairs in English or other foreign authorities. The kingdom of the Gotar probably ended soon after the 6th century.

At a later time the kings of Norway claimed descent from the ancient royal house of the Svear, and their traditions, though in great part mythical, prove at least its high antiquity. They trace its origin to the god Frey, son of Niorðr, who is said to have founded Uppsala, the ancient capital of Sweden. Among his descendants Athils, the Eadgils of *Beowulf*, is a prominent figure; in general, the account given of him agrees with *Beowulf*.

Early Kings.—Four generations after Athils' time a king named Ingialdr was overthrown by a prince from Skane, called Ivarr Viðfaðmi. His son Olafr Tretelgia withdrew to Varmland, which he brought into a state of cultivation, though he was subsequently sacrificed by his subjects in a time of famine. The sons of Olafr Tretelgia moved westward into Norway, and if we may trust later traditions Sweden passed out of their family. The subsequent kings of Sweden are said to have been descended from Ivarr Viðfaðmi. About 830 the missionary bishop Ansgar made his way to Birca on Lake Malar. For more than a century after Ansgar's death no serious mission seems to have been attempted.

During the 9th century extensive Scandinavian settlements were made on the east side of the Baltic. The famous expeditions of Rurik and Askold which resulted in the origin of the Russian monarchy appear to have taken place toward the middle of the century, but it is not possible to connect these names with any families known from Swedish tradition. Many names in Russian chronicles seem to be Swedish.

The continuous history of Sweden begins in the early 10th century, when a king named Eric son of Emund was reigning at Uppsala. Before the end of the century his descendant Olaf Skottkonung had created what for the moment was the strongest kingdom in the north. Under him Christianity was established in Sweden. As a leading ally in a coalition which included Sweyn, king of Denmark, and Eric, jarl of Lade, he overthrew Olaf I Tryggvesson, king of Norway, and annexed for a time part of Trondheim and the district now called Bohuslan, which he handed over to Sweyn Jarl, brother of Eric Jarl, as a marriage portion for his daughter Holmfrið. Several years later another Norwegian prince, Olaf II Haraldsson the Fat, returning to Norway as king, put an end to the Swedish and Danish supremacy and in 1015 forced Sweyn Jarl to leave the country. An attempt to arrange an alliance between Olaf Skottkonung and Olaf Haraldsson (who married a Swedish princess) was unsuccessful, and their relations were still strained when the former died, probably in the winter of 1021–22.

Anund, his son, early in his reign allied himself with Olaf Haraldsson against Canute of Denmark, who had demanded the restitution of the rights possessed in Norway by his father, Sweyn. The allies took advantage of the Danish king's absence to harry his land. On his return an indecisive battle was fought at Helgi Å, and Anund returned to Sweden. Olaf was driven from Norway by the Danes, but in 1030 he raised a small army in Sweden only to meet his death at the battle of Stiklestad. Anund, who died about 1050, according to Adam of Bremen, was succeeded by his brother Emund the Old, who had been previously passed over because his mother was unfree, the daughter of a Slav prince captured in war. This king had become a Christian, but soon quarrelled with Adalbert, archbishop of Bremen, and endeavoured to secure the independence of the Swedish church, which was not obtained for another century. Under Emund there was a rectification of boundaries which assigned Blekinge to Denmark.

With Emund's death in 1060, the old family of Swedish kings died out. He was succeeded by his son-in-law Steinkel, a noble of

Vastergotland, who was warmly attached to the Christian religion, though he refused to destroy the old sanctuary of idols at Uppsala. During his reign grants of land in Varmland made by the king to the Norse jarl Haakon Ivarsson led to a successful invasion of Gotaland by Harald III Hardraade of Norway. Steinkel also had disputes with Denmark. His death in 1066 was followed by a civil war, and for the next 15 years the history of Sweden is very obscure. In 1081 we find the sons of Steinkel, Inge and Halstan, reigning. Inge's attachment to Christianity caused him to be expelled after a short time by his brother-in-law Sweyn or Blotsweyn, so called from his revival of the old sacrifices, described by Adam of Bremen. Sweyn retained the kingship for only three years before Inge returned and slew him.

Organization of the Kingdom.—Under Blotsweyn's grandson, King Sverker (1134–55), who permanently amalgamated the Swedes and Goths (each of the two nations supplying the common king alternately for the next 100 years), Sweden began to feel the advantage of a centralized monarchical government. Eric IX (1150–60) organized the Swedish church on the model prevalent elsewhere and undertook a crusade against the heathen Finlanders, which marks the beginning of Sweden's overseas dominion. Under Charles VII, the archbishopric of Uppsala was founded (1164). But the greatest mediaeval statesman of Sweden was Birger Jarl, of the powerful Folkungar family. He practically ruled the land from 1248 to 1266. He founded Stockholm, but he is best known as a legislator who prepared the way for the abolition of serfdom. The increased dignity which the royal power owed to Birger was still further extended by King Magnus Ladulas (1275–90). Both these rulers adopted the dangerous expedient of creating a number of almost independent duchies in Sweden, but the danger of weakening the realm by partition was averted, though not without violent complications. In 1319 the severed portions of Sweden were once more reunited. Meanwhile the political development of the state was steadily proceeding. The formation of separate orders, or estates, was pronounced by Magnus Ladulas, who extended the privileges of the clergy and founded a hereditary nobility (Ordinance of Alsno, 1280). In connection with this institution we now hear of a heavily armed cavalry as the kernel of the national army. The knights too became distinguishable from the higher nobility. To this period belongs the rise of a prominent burgess class, as the towns began to acquire charters. At the end of the 13th century and the beginning of the 14th provincial codes of laws appeared and the king and his council executed legislative functions.

Union of Kalmar, 1397.—The first union between Sweden and Norway occurred in 1319, when the three-year-old Magnus, son of the Swedish royal duke Eric and of the Norwegian princess Ingeborg, who had inherited the throne of Norway from his grandfather Haakon V, was in the same year elected king of Sweden (Convention of Oslo). A long minority weakened the royal influence in both countries, and Magnus lost both his kingdoms before his death. The Swedes, irritated by his misrule, superseded him by his nephew Albert of Mecklenburg (1365). In Sweden, however, Magnus' partialities and necessities had led directly to the rise of a powerful landed aristocracy and, indirectly, to the growth of popular liberties. Forced by the unruliness of the magnates to lean upon the middle classes, Magnus summoned in 1359 a primitive form of the *riksdag*, on which occasion representatives from the towns were invited to appear along with the nobles and clergy. His successor, Albert, was forced to go a step farther and, in 1371, to take the first coronation oath. (X.)

The Swedish nobles, however, remained dissatisfied with the rule of Albert of Mecklenburg. In 1388, therefore, they called in Margaret (*q.v.*), Valdemar IV Atterdag's daughter and successor on the Danish throne, who became queen of Sweden also in 1389. Norway was already united with Denmark, and Margaret's plan was to bring all the three kingdoms together into a single union under Denmark. An act of union was drawn up at Kalmar in 1397 but was not proceeded with as the queen was dissatisfied with some of its clauses. At the same time her relative Eric of Pomerania was elected future king of the three kingdoms. After Margaret's death in 1412 he assumed the government and proceeded to try to change Sweden into a vassal country with the help of a system of Danish bailiffs. The consequent oppression became so hard that the Swedish peasants rose in 1434 under the leadership of Engelbrekt Engelbrektsson, a noble from Bergslagen. The national movement spread swiftly and the Danish strongholds were conquered. In the course of this fight for freedom Engelbrekt called together at Arboga, in Jan. 1435, the first *riksdag* in which nobles, priests, burghers and peasants were all represented. In 1436 Engelbrekt was murdered. For several decades a party in favour of the union, made up of the more important nobles and the clericals, with Danish support, proceeded to contend against a national democratic party under native leaders taken from the nobles. Danish kings were on several occasions recognized as rightful sovereigns also of Sweden, among them, for instance, Christopher of Bavaria (1440–48), in whose reign there was enacted in 1442 a new general law which, with additions, held good until 1734, and Christian I (1457–64). In between, a Swedish nobleman, Karl Knutsson, was recognized king (as Charles VIII) during the years 1448–57, 1464–65 and 1467–70, being twice expelled and twice reinstated. During the years that followed no native-born sovereigns were set up against the Danish kings, but the national party was under the leadership of *riksforestandare*, or regents, in the persons of members of the Sture family. After *riksforestandare* Sten Sture the Elder (1470–97) came the Danish king Hans (1497–1501), then Sten Sture again, (1501–03), and then Svante Sture (1504–12) and Sten Sture the Younger (1512–20). The times were troubled and there were continual struggles with the Danes. Many Germans lived in the towns. After a Swedish victory over the Danes at Brunkeberg in 1471 an old ordinance by which the Germans should have half the seats in the town councils was abolished. The country now became impoverished, but the national feeling grew stronger than ever, concurrently with a hatred of Denmark caused by Danish intrigues against Sweden. After 1512 the aristocracy, led by Erik Trolle, sought reconciliation with Denmark. Things came to a climax when the Danish king Christian II conquered the country; and in 1520 Archbishop Gustaf Trolle, Erik's son, had the foremost men of the national party in Stockholm executed (the "Stockholm blood bath"). Among noteworthy events in this period may be mentioned the founding of Sweden's first university in Uppsala in 1477.

Gustavus I Vasa.—The Scandinavian union was represented by the Danish king living in Copenhagen. Denmark and Norway held the south, and foreign trade lay in the hands of the Hanseatic league. Sweden was a land of peasants, divided by provinces and inspired by all the local patriotism that troublous times evoke. Uppsala university had deteriorated, and the affairs of the Catholic Church had long been neglected by the Holy See.

A young Swedish nobleman, Gustavus (Gustaf) Eriksson Vasa, who had been treacherously carried off to Denmark as hostage and prisoner, in 1519 made his escape to Lübeck, where he won good friends. At the end of May 1520 he landed again in Sweden near Kalmar and quickly learned of the massacre in Stockholm, in which his father and brother-in-law had perished. He made his way up to Dalecarlia, where he raised his first peasant troops. He had neither arms nor money, but one province after another came to his support. Archbishop Trolle, his foremost opponent, had to take flight from Sweden. Gustavus formed an engagement with Lübeck, which sent ships with arms and soldiers. In June 1523 Gustavus was elected king of Sweden by an assembly in Strangnas, and Stockholm surrendered to him.

But it was not easy to guard what had been won. Lübeck had secured for itself a monopoly of Sweden's foreign trade as well as exemption from tolls and bonds for very considerable sums in payment for services rendered. Drastic taxation had to be imposed, and the churches and monasteries also were requisitioned for help. Archbishop Gustaf Trolle was a fugitive, and the Swedish church found itself in a state of dissolution. Gustavus Vasa's first appeals to the pope were for bishops of Swedish birth, a new archbishop and church reformation. No favourable response came from Rome, and in these circumstances the king was influenced by Lutherans. The New Testament was translated into Swedish. At the *riksdag* held in Vasteras in 1527 the church settlement decreed

that the bishops had to hand over their castles to the king, and the chapters and canons, moreover, their superfluous incomes; that Peter's pence should no longer be paid to the pope; and that the pope's authority should not be invoked for the election of bishops. The year afterward the king was crowned in the cathedral of Uppsala.

Gustavus Vasa had to defend the interests of the kingdom against the individual claims of the provinces. The peasants had become disturbed by the novelties of the Reformation, and an adventurer came upon the scene, declaring he was Sten Sture's son. Disturbances broke out but the king put them down with severity. Christian II had been driven out of Denmark also, and this produced a *rapprochement* between Sweden and Denmark. Finally Christian was incarcerated in a Danish prison in 1532. Meanwhile, Lübeck's privileges had come to be intolerable. In 1531 every church was called upon to hand over its largest bell to supply means for meeting the Lübeck liabilities. Lübeck declared war on Denmark and Sweden; with the help of German allies its forces took Copenhagen and Malmo. They could not hold out, however, and in 1536 peace was declared. In the following year a treaty was framed between Sweden and Lübeck regarding certain exemptions from tolls but without trade monopoly. Sweden's debts were declared to be settled.

King Gustavus had now to organize administration. He heard talk about Roman law as the basis of all law. He consequently called in a great number of Germans, so that the years 1538–44 came to be known as the "German period"; but the Germans were for the most part adventurers and the results were not satisfactory. The newcomers caused the king to distrust his earlier helpers. There was a dangerous outbreak in Smaland, led by a peasant, Nils Dacke, who was killed in 1543. The influence of the Germans then ceased, and Gustavus ruled alone. He devoted great attention to mining, trade and agriculture. An influential landed nobility was restrained. At the *riksdag* meeting of 1560 the king presented his testament. He died on Sept. 29 of that year, aged 64. He was the founder of the new Sweden.

Eric XIV.—Gustavus Vasa's eldest son succeeded. Scholarly, display-loving, wayward, he ruled well at first but became insane. Gustavus had bestowed on his other sons dukedoms which entailed discords between them. On the occasion of his coronation Eric created the ranks of counts and barons, but he was mistrustful of the nobles, upon whom he imposed great exactions. He entered into negotiations for marriage with Queen Elizabeth I and afterward with Mary Stuart, as well as with two princesses on the continent, but met with refusals. Toward the close of his reign he married his low-born mistress, a good-hearted woman, Karin Mansdotter.

When the Teutonic Knights of Estonia and Livonia ceased to be, the town of Tallinn and the neighbouring region went over of their own accord to Sweden. This was the first step toward a Swedish sovereignty over the Baltic south of the Bay of Finland. The situation pointed ominously to coming conflicts, for Russia took Narva, the Danish duke Magnus took Osel and Poland took a large portion of the Teutonic Knights' country.

A break with Poland resulted in internal dissensions, as Eric's brother John, who was duke of Finland, married Catherine, the sister of the Polish king Sigismund II, and as security for a loan to his brother-in-law got some Polish castles in Livonia. A brief civil war took place. Eric's troops took Abo, and John and Catherine were put in prison, after being tried and sentenced by the *riksdag*. Negotiations were entered into with Ivan IV the Terrible in Russia and ended with a proposal for a treaty containing the condition—a blot upon Eric's name—that Duke John's wife should be handed over to the tsar, evidently to be used as a means of enforcing concessions from the Polish king. The shameful clause may be ascribed to Eric's madness, and it was never enforced. A severe conflict ensued with Denmark, which wished to have the union preserved and kept Sweden's "three crowns" in its coat of arms. Eric wanted to break the cordon in the south and would not recognize Denmark's claims to supremacy over the Baltic. He ostentatiously added the Danish and Norwegian kingdoms' arms to his own. Other disputes followed, and war resulted in 1563. The Swedish fleet won victories but the Danes had the mastery in the war on land, which was waged on both sides with grim ferocity. Lübeck and Poland allied themselves with Denmark. In 1567 Eric's insanity became manifest. He had some of the foremost nobles imprisoned, murdered one of them himself and had others of them assassinated. He became penitent and set free Duke John, who, in alliance with his younger brother Charles and the nobles, dethroned and imprisoned Eric in 1568. He died in prison in 1577.

John III.—John, an amiable man, learned in theology but irresolute and weak, was acclaimed king. The Danish war died a natural death through the economic attrition of both powers, and in Dec. 1570 peace was declared at Stettin through Polish and French mediation; the frontiers remained the same as before the war. Gotland was allotted to Denmark; Alvsborg on the west coast was to be surrendered by Sweden with a large sum of money; the question of the three crowns was left for later decision, but in the meantime Denmark was free to incorporate them in its arms; the Danish and Norwegian arms were to be taken out of the Swedish coat of arms. Sweden's gain consisted in the fact that from this time forward it was to be considered Denmark's equal as a Baltic state. Between Sweden and Poland good relations sprang up at once, but war broke out with Russia, waged with changing fortunes and occasionally interrupted by armistices. As a result the whole of Estonia, with Narva, was incorporated with Sweden.

The great religious struggle in Europe was followed with interest by John, who sought to take up a mediative role and entered into negotiations with the pope. Both papal and Spanish envoys came to Sweden, and it looked as though the king would go over to the Catholic Church, but when the pope refused to accept his offer of mediation he changed his tone and entered into definite opposition to Rome. He had previously given out a liturgy which evoked general displeasure in Sweden by its approach to the Catholic form of religious services; taken as a whole, his religious measures caused great unrest. His son Sigismund adopted the Catholic faith and was elected king of Poland in 1587. The internal administration of the country was marked by continual lack of funds (despite high taxation) and at the same time by extravagance over new buildings. Falls in the currency made the financial situation worse. The nobles were rewarded by special privileges for their part in the overthrow of Eric—a departure from the more democratic policy of Gustavus and Eric. The nobles now showed a tendency to aggrandize their powers, but the peasants never became serfs and the *riksdag* of the four estates continued to be called together. There were serious complications when John died in 1592.

Charles IX.—The crown went to Sigismund, who was scantily gifted, obstinate and a devoted servant of the Catholic Church; his uncle Charles on the other hand was a practical man of affairs, passionate and hard. The evangelical learning had taken still stronger root, and at a church meeting in Uppsala in 1593 it was decided to abide by the Holy Scriptures, the three great symbols and the unmodified Augsburg Confession. Sigismund was forced to agree. On the day previously, however, he had protested to the papal nuncio against the undertaking, and he considered himself entitled to disregard it. He returned to Poland in 1594. Duke Charles and the council soon fell out, with the result that the leading members of the council went off to see Sigismund. In 1598 Sigismund landed with a small Polish army, but he suffered defeat and returned hastily to Poland. This caused the Swedish *riksdag* in 1599 to declare him dethroned. Charles took a sanguinary revenge. The captive members of the council were executed.

Duke Charles was not crowned until 1607. He aimed at a monarchical-democratic conception of government. During the years 1561–93 the *riksdag* or other estates were convened 15 times; during Charles's much briefer reign, 1594–1611, they were called together 16 times. New church dissensions were caused by the fact that Charles cherished Calvinistic ideas while the clergy and the people expressed themselves more and more strongly in favour of evangelical tenets. By the peace with Russia concluded at Teusina in 1595 Sweden's ownership of Estonia and Narva had been recognized, but the troubles in Russia evoked new conflicts.

Swedish troops marched into Moscow, and the Russian crown was offered to one of Charles's sons. Novgorod was conquered. War with Poland was waged in Livonia, where the Poles won certain advantages without being able to turn them to account. Because of Charles's endeavour to extend the region of Finnmark up to the arctic under the rule of Sweden, and from other causes, war broke out with Denmark in 1611 and Kalmar was taken by the Danes. When Charles died in 1611 he left to his son, Gustavus Adolphus, an inheritance of three unfinished wars.

Gustavus II Adolphus.—Gustavus Adolphus, born in 1594, was declared of age on his father's death. He had been given a thorough classical education and spoke Latin and several modern languages. He was an organizer of great capacity both in military and in internal administration. His personal influence was attributable to a strong and good character and a clear and far-sighted vision. In all his work he had assistance of extraordinary value from his chancellor of state Count Axel Oxenstierna (*q.v.*).

The Danes were successful in the war and took the harbours on the west coast. Through the mediation of King James I of England peace was concluded in 1613. The peace conditions were hard: Alvsborg was to be handed back to Sweden in return for a payment of 1,000,000 dalers within six years; the Finnmark region was given to Denmark-Norway; and the right of the Danish king to use the Swedish three crowns in his coat of arms was recognized.

Sweden next desired peace and a fixed frontier with Russia. The war was continued until the conclusion of peace at Stolbova —also with King James's mediation—in 1617. Sweden won eastern Karelia and Ingermanland, whereby land connection was obtained between Finland and Estonia, but gave up Novgorod. During and after these wars a great task of organization was carried out in Sweden. The council acquired a stronger position as the king's advisers at the head of the administration. Ministerial offices were set up after the French-Burgundian model; a method of judicial procedure was instituted and courts of appeal were established. The nobility was incorporated in the social system as officials of the government, and much was done to improve local administration. The king promised not to begin war or conclude peace or make a treaty with other powers without the sanction of the *riksdag*. The ransom of Alvsborg made heavy taxes necessary, and even so the town of Amsterdam had to help with a loan. The financing of the state and the raising of the loan were based in a high degree on the copper ore in the Falu mines. In Jan. 1619 the ransom sum was paid and Alvsborg was returned to Sweden. Gustavus Adolphus endeavoured to promote commerce. New towns were founded, of which Goteborg on the west coast was the most prominent (1621). A source of future difficulties lay in the privileges of the nobles. Their graduated freedom from taxes—the reward of the servants of the state—was to diminish thereby the state's revenue from taxation; this danger, however, did not present itself until later. The nobility secured the stability which it needed through the founding of the *riddarhus*, or house of the nobles, in 1626, in which records were inscribed of the noble families. Higher education was furthered. The University of Uppsala got from the king in 1624 a great donation of lands. Great attention was given to the equipment of the army and navy. Relations with Poland were settled by armistices until the year 1617, when negotiations led to no result. Sigismund had never abandoned his claim to the Swedish crown and therein lay a menace for the future. Open war began again and Gustavus Adolphus took personal part in it. Livonia and Riga were conquered, and for several years the Swedes carried the war into Polish Prussia. Through the mediation of Brandenburg, France and England, a six years' truce was agreed to at Altmark in Sept. 1629; some Prussian seaports continued to be Swedish possessions, the Swedes retaining the right to levy tolls.

Meanwhile the great conflict that was to be known as the Thirty Years' War (*q.v.*) had started within the German kingdom, and Sigismund's efforts were menacing to the religious peace of Sweden. The emperor's troops were sent to Prussia to help Poland. The royal houses of Sweden and Denmark were related to German princes who asked for help. Catholic France sought to check the emperor's increasing influence and negotiated with Sweden and Denmark; the English government was working to the same end. Christian IV of Denmark entered into the war but was completely defeated, and Wallenstein's imperial army took up its position on the Baltic. Wallenstein was made duke of Mecklenburg and imperial admiral over the Atlantic ocean and the Baltic; an imperial fleet was to be built. When Stralsund was threatened, Gustavus Adolphus sent help (1628), and after long and many deliberations with the council and the *riksdag* he made his way with 13,000 men to Pomerania in June 1630; he preferred to have Germany as his theatre of war rather than to await an attack in Sweden. When success attended his invasion of the country, France concluded a subsidiary treaty with him at Bärwalde in Jan. 1631. The evangelical princes of Germany took up a dubious attitude at first, and the Swedes were blamed when they did not succeed in relieving the town of Magdeburg, which was taken by the imperial general Tilly. After various negotiations, a decisive victory was won at Breitenfeld in Sept. 1631.

A series of brilliant Swedish successes followed. Gustavus Adolphus held his court in Mainz and Frankfurt, crossed the river Lech and made his entry into Munich. The emperor had dismissed Wallenstein in 1630, but now took him back into favour, and soon the latter was once again in the field with a strong army. The Swedes vainly stormed his fortified camp at Nuremberg, and the brisk war which ensued led to the battle of Lützen in which Gustavus Adolphus met his death on Nov. 16 (O.S. 6), 1632.

It may be thought a matter for wonder that Sweden, a country with a population relatively so small, should have been capable of so great a political and military expansion as was shown in the Thirty Years' War. The explanation lies partly in an extraordinary national effort to avert an imminent danger. Sweden's armies were made up also in an increasing degree of foreign mercenaries, German, English and Dutch. In the Polish war a number of excellent Swedish generals had learned their business, and Gustavus Adolphus was one of the foremost military leaders of the time.

Christina.—The death of Gustavus Adolphus produced a crisis in Germany. His daughter Christina, still a minor, was recognized as queen (1632–54) and the regency was undertaken by Axel Oxenstjerna. It was well that a new treaty was concluded with France in 1633 and that Wallenstein was murdered in Feb. 1634, but in the autumn the Swedes suffered a defeat at Nördlingen which lowered their prestige. In 1635 Saxony concluded peace with the emperor, and its example was followed by Brandenburg in 1636; both declared war against Sweden. Johan Banér (*q.v.*) restored the good name of the Swedish troops by victories at Wittstock in 1636 and Chemnitz in 1639. His successor, Lennart Torstensson (*q.v.*), thrice invaded the emperor's dominions and won the second battle of Breitenfeld in 1642. Almost everywhere Swedish interests were opposed by Denmark. Torstensson was ordered, therefore, to leave Bohemia for Denmark in 1643, and Jutland was overrun by Swedish troops. Christian IV was forced to conclude a peace at Bromsebro in 1645 by which Sweden won Jamtland, Harjedalen, Gotland, Osel and, for 30 years, Halland; exemption from the Oresund tolls was accorded for goods to Sweden and the Baltic provinces. By the treaty of Westphalia (*see* WESTPHALIA, PEACE OF) Sweden acquired important German possessions—portions of Pomerania, Wismar, the bishoprics of Bremen and Verden as fiefs of the German empire, and prize money as rewards for the soldiers. A number of Swedes had in the course of the war amassed fortunes; the influence of the nobles in this way had been increased and a chasm had grown between them and the unprivileged classes. This was intensified by the circumstance that many foreigners had entered into Swedish service and had been rewarded with landed estates. Through them and through the impressions which Swedes had gathered in foreign countries, new ideas regarding the social status of the nobles had become prevalent.

The exercise of governmental power and the administration of the state in general were regulated by the constitution of the year 1634. Christina came of age in 1644, but laid down the crown ten years later. Richly endowed by nature, she had acquired much learning and many accomplishments but she was flighty and arbitrary, wont to overload with gifts those who were momentarily

in her favour. She went over to the Catholic church and died in Rome in 1689 after a life not lacking in excitement.

Charles X Gustavus.—Her successor was Charles Gustavus, son of Charles IX's daughter Catherine, who had married John Casimir of Palatinate-Zweibrücken. He had been brought up in Sweden, becoming *generalissimus*. The costs of the court were cut down, and in the *riksdag* of 1655 the nobles agreed that the endowed estates necessary for administration of the kingdom, for defense of the realm and for working the mines should return to the crown, that certain estates bestowed as gifts should acquire the character of fiefs with right of return to a new king, while a fourth of such estates as had been bestowed after the year 1633 should be returned to the crown. This measure was put into effect at once but ceased to operate during the strenuous war years that followed.

Charles X's short reign was occupied by war. With Poland there was as yet no peace; as the Russians had directed an attack against Poland, the king and the *riksdag* decided to settle the matter by means of a war. Charles X took Warsaw and Cracow (1655). Poland looked as though lost, but a national rising followed in favour of King John Casimir and two years of fruitless fighting resulted. Charles X concluded peace with the rising power, Brandenburg, and the Swedish and Brandenburgian armies together won a three days' battle at Warsaw in 1656. In that year the Russians began war and the emperor joined Sweden's enemies, and the following year Denmark, Holland and Brandenburg followed suit. If all these powers could have co-operated closely Sweden's position would have been extremely perilous, but they could not. Charles turned resolutely upon Denmark, took Jutland and led his troops first over the ice to Fyen and then across the islands to Sjalland. The credit of this military exploit belongs chiefly to the quartermaster general of the army, Erik Dahlberg. Denmark was forced to make peace in 1658 at Roskilde, Sweden receiving Skane, Halland, Blekinge and Bornholm, Bohuslan and Trondheims Lan. Both kingdoms undertook to make common cause to keep enemy fleets out of the sound. The king now thought of confronting his other enemies, but as certain negotiations with Denmark did not quite take the turn he expected and the Dutch were busily agitating in Denmark, he guessed that hostilities from this country would follow the moment he had become engaged in the east. He resolved to avoid this danger by completely crushing Denmark and began war anew in Aug. 1658. His policy, however, failed, as in Poland, through a contingency with which the statesmen of those days seldom reckoned—the kindling of a national patriotic movement. Copenhagen withstood his attack and Holland sent a fleet which after a fierce struggle with the Swedes relieved the Danish capital. The situation was anxious, and a *riksdag* was called together at Goteborg. Charles X Gustavus died on the night of Feb. 12–13, 1660, during its session.

Charles XI.—Charles XI, a boy of four, succeeded his father as king at a moment when Sweden was surrounded by enemies. The widowed queen and five officials became regent. The first thing done was to secure peace: with Poland, the emperor and Brandenburg at Oliva in 1660, whereby Sweden's right to hold Livonia was recognized and John Casimir renounced all claim to the Swedish throne; with Denmark the same year at Copenhagen, whereby Trondheims Lan and Bornholm went back to Denmark, compensation being given in the case of Bornholm; and with Russia in 1661 at Kardis, confirming the peace of Stolbova. Magnus Gabriel de la Gardie, the chancellor of state, was weak, and none took the lead in the way Axel Oxenstjerna had done after the death of Gustavus Adolphus. The nation's defenses were allowed to decline although its foreign policy was adventurous. It was desired to obtain subsidies from other powers, and a rash treaty was concluded with France in 1672. In this year the king came of age, having reached his 17th year. His education had been neglected and he grew up awkward in his bearing, but he was an ardent patriot and extremely industrious.

The general decadence of Sweden became manifest when its foreign policy led to war with Brandenburg (1674) and Denmark (1675). The war with Brandenburg was ill managed, and Sweden's military prestige was lowered by a defeat at Fehrbellin in 1675; most of its German possessions were lost. The Danes invaded Skane where they continued to have many friends. The king took the leadership. On the sea the Danes were successful, but Swedish victories at Lund in 1676 and other places saved the southern provinces. Peace treaties were signed in 1678 and 1679 with the different enemies. France accepted terms which in some respects were humiliating for her ally Sweden. Some small regions in Germany were lost, but there was no question of any cession of land to Denmark.

Great portions of the country had been laid waste, the fleet had been destroyed, trade and commerce had suffered and finances were in disorder. A great task lay before the young king and he accomplished it, but it was by the methods of an absolute monarchy. The *riksdag* was summoned several times—1680, 1682–83, 1686, etc.—but its attitude toward the king grew more and more complaisant and it gradually came to leave practically all matters of legislation and taxation to him. An inquiry was held into the conduct of the members of the regency, and they were sentenced to restore or pay large sums of money; a very drastic confiscation of private estates was taken in hand whereby land and incomes were made to fall to the treasury. Charles then put the army and navy in good trim. The officers were remunerated by small farms; cavalry was raised by a certain number of assessed farms and the infantry by the landowners. In the year 1681 the Swedish national debt amounted to 44,000,000 dalers in silver, but on Charles's death it was only 11,500,000 dalers. Charles married the Danish princess Ulrica Leonora, but the two northern states soon fell apart again. In 1681 Sweden entered into treaties with Holland at The Hague with a view to safeguarding the frontiers fixed by the peace treaties of Westphalia and Nijmegen. The emperor gave his signature to the compact the following year. Sweden wanted to draw Holstein into its sphere of interest so as to secure less interrupted communications between its different German possessions; Charles therefore gave what support he could to his maternal uncle Christian Albert, duke of Holstein-Gottorp, in his disputes with Denmark. For Denmark, conversely, it was important to hinder the Holstein plans of expansion lest Denmark should be hemmed in on the south. Charles XI died in April 1697, leaving one son, Charles, and two daughters.

Charles XII.—For the third time in the 17th century a regency was called on to act, but in Nov. 1697 the *riksdag* declared the 15-year-old Charles XII to be of age. At the coronation he placed the crown on his own head and gave no *kungaforsakring* (literally "king's guarantee"). Charles was a gifted and precocious youth who had been grounded in book learning and military science. He had high morality, but was inclined to obstinacy. In his early youth he was addicted to wild pranks and perilous sports. Within three years of his accession, however, the Great Northern War (1700–21) had broken out.

Poland, Denmark and Russia were united against Sweden. In March 1700 the Poles marched on Riga and the Danes against Holstein. The young king showed unusual power and decision. Protected by the English and Dutch fleets he landed on Sjalland (Zealand) and enforced on Denmark the peace of Traventhal in Aug. 1700. In November the Swedes, under the personal leadership of Charles, won a momentous victory over the Russians at Narva. In the summer of 1701 Charles marched south, drove the Russians and the Saxons over the Duna and invaded Poland. Charles called upon the Poles to dethrone Augustus II the Strong who had begun the war. This stirred the national feeling of Poland and won Augustus help from other states. Charles's route went through Kaunas in Lithuania to Warsaw and Cracow which he took (1702). After continual but fruitless victories for the Swedes a Polish parliament, not constitutionally formed, declared Augustus dethroned and elected as his successor Stanislaus Leszczynski, a weak man who lacked the strength to defend his own status as king. The Polish parliament concluded peace with Sweden in 1705. In this way Poland became a kind of subject state to Sweden, but Charles miscalculated Sweden's capacity for maintaining such a relationship. During these Polish conflicts the tsar Peter took town after town in Livonia and Ingermanland, among them Dorpat and Narva. Charles, in the meantime, held

that the most important thing was to force Augustus to conclude peace before he took up his stand against Peter, and he carried war into Saxony. The Swedish army was now one of the most famous in Europe, and Charles's power was very great. Leipzig was taken, and Augustus, by the peace signed for him by his ministers at Altranstädt in Sept. 1706 and ratified by him in October, renounced the Polish throne and allowed Charles to remain some time in Saxony with his army. Augustus sought by intrigue to overrule the peace treaties but had to reaffirm them in Jan. 1707. From different quarters came efforts to benefit by Swedish aid; nearly a dozen German princes sought Charles out, and he was visited by 30 envoys from various courts. The most notable of them was the duke of Marlborough, who took note that the Swedish king did not intend to place himself on the side of France in the War of the Spanish Succession as rumour had declared. Quarrels with the emperor began, but with the help of English and Dutch mediation a peace was concluded in 1707 which secured for Protestants in Silesia the church rights promised them in the peace of Westphalia.

Charles was anxious to come to conclusions with Russia, but he had given the tsar too long to prepare. The Russians had forced their way into Poland but were driven out again, and after a victory at Holowczyn (July 1708) Charles crossed the Dnieper. Adam Ludwig Levenhaupt was to have come with an army from Livonia to his support but was delayed and experienced a severe defeat, arriving eventually with a diminished force and without commissariat. Devastations by the Russians made it difficult for the Swedes to provide themselves with necessaries, and when the Cossack Ivan Mazepa-Koledinsky offered his co-operation Charles concluded a treaty with him in Oct. 1708. Mazepa did not manage to get his Cossacks to join with him, but Charles advanced into the Ukraine. In an unusually hard winter thousands of Swedish soldiers perished. Charles began to lay siege to Poltava; the battle which followed (June 28, 1709) ended in a Swedish defeat, largely because of the fact that Charles was wounded in the foot and that his generals were not united. Charles made his way as a fugitive to Turkey and his proud army capitulated at Perevolochna on July 1, 1709.

The unfortunate Russian campaign made an immense impression both in Sweden and in other countries. Augustus declared the peace with Sweden invalid and marched into Poland. The Danes crossed the sound and sought to overrun Skane. The government in Stockholm put forth all its powers to defend southern Sweden, and Magnus Stenbock won a decisive victory at Helsingborg in Feb. 1710. The Danish troops were taken back to Denmark. The Russians occupied the Baltic provinces completely after they had taken Riga. Meanwhile Charles was busying himself in Bender trying eagerly to bring about a war between the Turks and Russia. His stay in Turkey is difficult to explain; probably he did not want to return until the Russians had been either conquered or weakened. Thrice the Turks began war but without any gain to Sweden. Meanwhile Stenbock made his way to Germany, but though he defeated the Danes, who had overrun Bremen and Verden, at Gadebusch (1712) he was forced to capitulate with his army at Tönningen in 1713. The Russians and Saxons failed to take Stralsund, but in 1713–14 the Russians swarmed over Finland.

From Feb. 1713 Charles was held captive by the Turks, but after a swift journey he arrived at Stralsund in Nov. 1714. The country was in a sad plight. The population was only 1,250,000 and the burden of the great war was too heavy. The people were oppressed by heavy taxes and services imposed by the state and worn out by conscription.

During the years that followed Charles XII strengthened Sweden's defenses against the Danes, who received help from a Russian army and threatened an invasion of Sweden. The plan was not carried out, and Charles turned toward Norway to force the Danish king to make peace. While there he was killed by a bullet on Dec. 11 (O.S. Nov. 30), 1718.

In Stralsund Charles had made acquaintance with the Holstein baron von Görtz, who afterward became his confidant and associate. Unscrupulous and resourceful, Görtz discovered new means of taxation, simplified the state administration, lowered the value of the currency and conducted an adventurous policy abroad. The poverty thus brought about evoked a hatred against him which after Charles's death led to his being tried and executed. With Charles the Swedish supremacy over the Baltic came to an end. Swedish forces were withdrawn at once from Norway, one brigade which was sent against Trondheim experiencing terrible losses in the mountains. The *riksdag* assembled for the special purpose of putting an end to the absolute power of the sovereign.

Ulrica Leonora.—Charles's sister, the younger Ulrica Leonora, married to Frederick of Hesse-Cassel, was declared not to be the successor to the throne but was elected queen (1718–20) on condition that the *riksdag* alone should have the right to draw up the constitution. The changes effected in the constitution drawn up in 1719 and 1720 and in the *riksdag* decrees of 1723 were drastic. When the *riksdag* was not in session the council ruled together with the king who on most questions had only two votes. While the *riksdag* was sitting, decisions on foreign affairs and other matters were made by a secret committee which was formed of members of the three higher estates, the nobles, the clergy and the burghers. The peasants were left in the background but they had to be heard on questions of taxation. Each estate chose its own speaker; in the house of nobles the speaker was called *landmarskalk*. The membership of the council could be revoked only by law, and this made parliamentary government very primitive because it led to political lawsuits.

In 1719 peace was concluded with Hanover on the basis of Sweden's giving up Bremen and Verden and receiving a sum of money in return. In 1720 an arrangement was come to with Prussia, which acquired a large part of Pomerania and also paid a sum of money. In 1720 also peace was made with Denmark, which renounced the regions it had conquered in return for being allowed to keep Schleswig. Russian fleets, however, were harrying the coasts of the Baltic, and an attack upon Stockholm was with great difficulty warded off. Peace was not concluded with Russia until 1721, at Nystad, when Sweden gave up Livonia, Estonia, Ingria and parts of Finland; northern and western Finland was restored to Sweden.

Frederick I.—In 1720 the crown was transferred to the queen's consort Frederick I (1720–51). The leading statesman until the end of the 1730s was Count Arvid Horn, who pursued a prudent peace policy. The state's debts amounted to 60,000,000 or 70,000,000 silver dalers, and the emergency currency (*nodmynten*) was working much harm. A state bankruptcy was inevitable, and after this the emergency currency disappeared. With the English Navigation act as a model, a proclamation was issued in 1724 prohibiting foreign vessels from conveying to Sweden anything except the produce of the countries to which they belonged. The Swedish commercial fleet increased, an East Indian company was formed in 1731 (which caused bad blood in England), new manufactories were founded with support from the state, in particular the textiles industry, thanks to Jonas Alstromer, who created the manufactory at Alingsas. A new general law was framed in 1734.

During the first years following the peace of Nystad Russia sought to intervene in Sweden's internal affairs. Horn therefore in 1726–27 made Sweden a member of the alliance between England, France and Prussia. Indeed, foreign subsidies began to have their ill effects in Sweden. Against Horn's prudent leadership there grew up an opposition which gained ground in 1734 and became victorious in the *riksdag* of 1738–39. Horn gave up office in Dec. 1738. The victorious party was called Hattar, "the Hats" in contradistinction from Mossorna, "the Caps."[1] The program of the Hats favoured war with Russia with a view to winning back the Swedish provinces and power and a more intensive industrial policy; Sweden was to become a great power politically and economically.

The party of the Hats controlled the fortunes of the country until the 1760s, although sometimes strongly opposed by the Caps.

[1]These party names originated in the Progressives' nicknaming their opponents—who sacrificed everything to perpetuate an inglorious peace—the "Nightcaps," they themselves receiving their name from the three-cornered hats that they wore as officers.

They dominated the council from 1739 onward with Count Karl Gyllenborg as their leader. Conditions seemed favourable for a war with Russia in 1741 and war began. The campaign was badly conducted and the Swedish troops took to flight. Discontented thousands of peasants marched to Stockholm and could be dispersed only with difficulty. At the beginning of the *riksdag* session in 1742 the Caps were in power, and the peasants now won for themselves a place in the secret committee. An inquiry was conducted into the actions of the instigators of the war, and two of the generals were condemned to death and executed. The Hats now raised the question of the succession to the throne, the royal couple being childless, and the question soon became bound up with that of the Russian peace, as the Russian empress Elizabeth wished to see Duke Adolphus Frederick of Holstein elected. The peasants particularly wanted to have the Danish crown prince, and a great conflict raged in *riksdag* circles, much bribing being done by foreigners. In June 1743 peace was concluded at Abo. Russia retained only a small portion of its conquests in Finland, and Adolphus Frederick was chosen as heir to the Swedish throne. Denmark threatened war and Sweden's impotence became manifest when a Russian army came to the country to protect it against the Danes. While the *riksdag* was in session there was a split among the Caps, and the council came to include both Hats and Caps. Adolphus Frederick came to Sweden and in 1744 married Ulrica (Ulrike), sister of the Prussian king Frederick II. Russia's disposition to control the destinies of the country now took on a singularly offensive aspect. Foreign gold filled the coffers of the parties before the *riksdag* of 1746–47 assembled. The Hats opposed the Russian proceedings resolutely and in this were supported by many of the Caps. Through new elections to the council, the Hats now came definitely into power again, with Count Anders Johan von Hopken as head of the government. Some members of the Caps party were charged with treason and the matter was investigated by a commission. This had the effect of diminishing their opposition to the Hats. An alliance was contracted in May 1747 with Prussia and France which improved the situation. The successful party rewarded its friends lavishly and came down heavily upon its foes.

The years which followed were comparatively quiet. The brilliant young noble Count Carl Gustaf Tessin was president of the council, which was the strongest known within the period of the *riksdag's* predominance; national defenses were strengthened, customs tolls were raised to help industry, which was also supported by loans and premiums; agriculture was supported also by loans on easy terms. The improvement secured by these measures was not entirely real, and great credits were extorted from the Riksbank, which had to increase its issue of notes. Notes depreciated in value and exchange offices were set up to keep the currency at the desired height.

Adolphus Frederick.—King Frederick died in 1751 and was succeeded by Adolphus Frederick (1751–71), who was under the influence of his stronger-minded wife. Controversial pamphlets and journals came out in numbers. Tension between the king and the council increased. A rash effort at a coup d'état was made during the *riksdag* of 1755–56; the royal couple was humiliated and an autograph stamp was introduced in order to dispense with the king's personal intervention in the government. Count Axel von Fersen came to the front as the foremost man in the Hats party; he was chosen as *landmarskalk* (*see* above), leading the bureaucracy of the nobles.

Opposition grew therefore among the unprivileged classes against the nobility and the bureaucracy. The state's finances were in a bad way, yet in spite of this the country was let in for a war, on the side of France and Austria, against Frederick II of Prussia (1757), largely because of the French subsidies. The war was badly managed, but peace was made with Prussia without loss of territory in May 1762. The Caps took office in the *riksdag* of 1765–66. Russia and Prussia together decided to support the Swedish constitution, to prolong its general state of weakness and at the same time to work against the French influence. A Russo-Danish alliance was also formed with the purpose of maintaining the Swedish constitution. England was on the same side and it is calculated that these powers spent 3,000,000 silver dalers in order to ensure the victory of the Caps, while France's contribution to the Hats amounted to 2,000,000 dalers. The corruption was shameful. Against the wishes of the royal couple, the crown prince Gustavus married the Danish princess Sophia Magdalena.

The court had helped the Hats during the *riksdag*, and by the king's direct intervention the council was obliged to call together the *riksdag* which sat from 1769 till 1770. The Caps were now in a minority and their men were left out of the council which was controlled by the Hats. The court had been promised that the king's power would be increased, but the Hats did not keep their word. Nor did the *riksdag* succeed in solving the great financial problems. In Feb. 1771 Adolphus Frederick died. Somewhat previously Russia and Denmark had come to an agreement that, should any change be made in the constitution of Sweden in the direction of increasing the king's power, they would uphold the existing constitution (Dec. 1769) by force of arms. Sweden's constitution therefore seemed to be held in greater value by its enemies than by its own people.

Gustavus III.—The crown prince was in Paris at the time of his father's death. He returned home to meet the *riksdag*. The Hats and the court party were receiving money from France, the Caps from Russia and England. The parties were of about equal strength. Gustavus now decided to precipitate a change of the constitution. Col. Jakob Magnus Sprengtporten crossed to Finland to stir up a rising, in which he succeeded but not so quickly as had been expected. Johan Kristoffer Toll (*q.v.*), a superintendent of forests, went to Skane and won over the garrison at Kristianstad. Prince Charles, the brother of the king, also busied himself in Skane. The council got wind of the danger and the king had to act speedily. On Aug. 19, 1772, he collected around him the officers of the guard and arrested the council in the royal castle. The Stockholm troops declared for him and the people acclaimed him in the streets. The king became again head of the government, with the right to appoint officials. It was an attempt to divide the balance of power between the sovereign and the *riksdag*.

Russia and Denmark were furious but did not begin war, being much influenced by the resolute attitude of France. Gustavus surrounded himself with capable men. He was unusually gifted, but too much of a visionary. He had a real passion for the theatre but took up his business as king with honest intent; an inquiry into the conditions of governmental offices was initiated and a number of reforms in the administration were instituted as a result. In order to help the finances distilling was decreed a state monopoly and a number of distilleries were founded on behalf of the crown. This displeased the peasants, who wanted to be free to distil, and it increased drunkenness. Another cause for dissatisfaction lay in the king's efforts to transform the nobility into a court nobility and to manage promotion so as to break the power of the old bureaucracy.

A dispute with his mother discouraged the king, who next visited Italy and Paris; a subsidy treaty was concluded with France but Gustavus had no great success there. During the *riksdag* of 1786 the situation became worse; most of the king's measures were rejected.

Then Turkey's war with Russia in 1787 seemed to offer favourable conditions for a successful foreign policy. He began war with Russia in June 1788, taking command himself. But the sea fight at Hogland was undecisive, and a conspiracy, known as the Anjala league, was formed by certain officers. The conspirators opened negotiations with the Russian empress, to bring about peace. News came that Denmark had entered the war as Russia's ally, and Gustavus was obliged to hurry back to Sweden. The Swedish people became animated by patriotism and the king talked to the peasants as Gustavus Vasa had done of old. England and Prussia brought pressure to bear on Denmark to leave Sweden in peace and a truce was concluded. By the beginning of the following year, 1789, Gustavus was strong enough to have the leaders of the Anjala league imprisoned. The *riksdag* was called together at the beginning of February. The meeting was

a stormy one, the king, supported by the unprivileged estates, driving through the so-called Act of Union and Security, which embodied a number of far-reaching constitutional innovations: the council ceased to exist; the king acquired full powers over the administration of the state and the appointing of officials; and the *riksdag* lost its initiative in legislation. Once again the authority of the king became dominant. The *riksdag* became responsible for the national debts, the management of which was placed in the hands of the *riksgaldskontor*, which was dependent on the *riksdag* and which was given the right to take up new loans and to issue credit notes. A number of the leaders of the opposition had been imprisoned in the course of the session. Such was the king's second revolution. (*See* GUSTAVUS III; WALLQVIST, OLAF.)

The Russian war became a war of exhaustion on land. During the years 1789–90 there were several sea fights, the second of which, at Svensksund in 1790, constituted a fine victory under the king's command. In Aug. 1790 peace was concluded without modification of frontiers. But Sweden's finances were destroyed and the internal strife brought to a head. One result was a conspiracy against the king's life. He died on March 29, 1792, from the effects of a murderous attack by Captain J. J. Anckarstrom at a ball in the opera house on March 16, 1792.

Gustavus IV.—At the age of 13 Gustavus IV (1792–1809) became king of Sweden with his uncle Duke Charles as regent. Duke Charles's closest associate was Baron Gustaf Adolf Reuterholm, a man of great powers of work but pedantic and of little intelligence. The regency brought order into the higher grades of government service and sought above all to further the prosperity of agriculture. Reuterholm was not lacking in appreciation of the latest reforms: the freedom of the press was at first increased, but when the horrors of the French Revolution broke out it was restricted. The repute of the regency did not stand very high. It wavered between a French and a Russian alliance. The king, the duke and Reuterholm visited the Russian court in order to arrange a marriage between the king and a Russian princess, but the whole thing fell through when the king refused to give a guarantee of the princess's religious freedom. On the basis of a treaty concluded in 1794 between the two countries, the fleets of both Denmark and Sweden sought to protect neutral trade against privateers of England and other nations.

In 1796 Gustavus IV took the government into his own hands. He was scantily gifted but he knew how to make himself felt and combined obstinacy with passionate temper. So bad were the finances that the town of Wismar had to be mortgaged to Mecklenburg in 1801. In the course of a long journey in Germany in the years 1803–04 Gustavus came into touch with French *émigrés*, who inspired him with hatred of Napoleon. He took part in the coalition against France in 1805–07, with the result that Pomerania and Stralsund were lost. In the treaty of Tilsit Napoleon and the emperor Alexander agreed to attack Sweden unless it declared war against England and prevailed on Denmark to do the same. The army in Finland gave way before the Russians. The strong fortress of Sveaborg was treacherously surrendered without any real struggle. In the spring the Swedes marched again to the south of Finland and won several victories, afterward immortalized by the poet J. L. Runeberg. In Dec. 1808 the Swedish forces evacuated Finland. Gustavus IV became more and more difficult and he annoyed even England, his only ally. The feeling grew that the king must be dethroned. Gen. Georg Adlersparre started a revolutionary movement in Varmland, but before he reached Stockholm Adj. Gen. Karl Johan Adlercreutz had secured possession of the king's person (March 13, 1809). The king died in exile in 1837.

Charles XIII.—The *riksdag* was called together on May 1 by the provisional government and it decided to draw up a new constitution and elect a king. The form of government which resulted was based on a division of power between the ministry, the representatives of the people and the judicature. The king was to be advised by a ministry the members of which were to be appointed by the king but to be answerable to the *riksdag*. General legislature was to be the work of the king and the *riksdag*, and the *riksdag's* control over taxation was confirmed. As soon as this constitution had been adopted Charles XIII was recognized as king (1809–18). The credit of drafting the new constitution belongs chiefly to Hans Jarta.

King Charles was childless and it was necessary to choose a successor to the throne. Public opinion in Sweden at this period occupied itself with Norway's union with Sweden as a compensation for Finland. The *riksdag* chose as successor to the throne Prince Christian Augustus of Augustenburg, who was commander in chief in Norway, manifestly in the hope that the choice would help to bring this union about. The prince declared that he could accept this offer only after a declaration of peace. During the late summer of 1809 the Russian war was extended to the north of Sweden and the Swedish forces met with two defeats. The Russians in the meantime had become weary of the war and in September peace was declared at Fredrikshamn (Hamina); Sweden lost Finland and Aland. Soon treaties of peace followed with its other enemies. Pomerania was returned to Sweden.

The heir to the throne, who took the name of Charles, died suddenly in 1810, and a *riksdag* at Orebro had again to deal with the question of a successor. Opinions were divided when a suggestion was made that they should elect one of Napoleon's marshals, Jean Bernadotte, prince of Ponte Corvo. It seemed certain that Napoleon would approve, and accordingly Bernadotte was chosen and assumed the name of Charles John, to become the founder of a new Swedish dynasty, the succession to the throne having been provided for in an ordinance passed in 1810. The old King Charles XIII had shown courage and patriotic feeling during Gustavus III's war with Russia, but he was not very intelligent and he lacked strength of character. The crown prince therefore began to exert considerable influence, with stimulating and beneficent results.

In 1811 Napoleon prepared to break down Russia's resistance. A great war began, and the crown prince perceived that Sweden could not possibly go into it with France against England and Russia. He seems early to have thought out his plans for the conquest of Norway, and in 1812 he brought about a complete change in Swedish policy with this goal in view. Napoleon's occupation of Swedish Pomerania without declaration of war facilitated this change, and Russia and England favoured the idea that Norway should pass over to Sweden from Napoleon's ally Denmark. After the defeat of the French armies in Russia Charles John took part in the final conflict as commander of the northern army, with Swedish as well as Prussian and Russian troops under him. With these the crown prince, after the battle of Leipzig, made a movement against Denmark, which by the peace of Kiel (Jan. 1814) was forced to hand over Norway in return for Pomerania.

The Norwegians themselves, desiring independence, held an assembly at Eidsvold in May 1814 where they framed a constitution and elected the Danish prince Christian Frederick as king; but they were forced as the result of a short war to surrender. Christian Frederick laid down his crown and a *storting* endorsed the union with Sweden. Special conditions affecting the union were framed in the act of union or *riksakt* passed by the parliaments of both countries in 1815.

Charles XIV.—Bernadotte succeeded to the throne, as Charles XIV John, in 1818. The industrial economic revolution, evolving new classes which claimed their share in the government and burst asunder the old methods of representation, began in Sweden during his reign and embittered his later years. He was a strong personality, capable and lovable but distrustful of new ideas and apprehensive of too great changes. A liberal opposition was formed in the *riksdag*, above all among the burghers, and took a strong line against the government's repression of newspapers, against bureaucratic formalities and against the king's tendency to disregard the advice of his ministers. From the 1830s onward there was a question of reform in the matter of the representation of the people, and a great many bills were put forward without accomplishing much. In 1840 the state council was changed by the creation of special departments. With the king's active cooperation the state's foreign debts were paid while internal debts were diminished, and in 1834 a regulation of the exchange was effected. Much was done for the canal system; one section of the

Gotha canal was opened in 1822 and the rest of it in 1832. In 1842 the board school system was changed.

Oscar I.—Charles XIV was succeeded in 1844 by his son, a man of gifts and of more open mind but of less strength of will than his father. During the earlier years of his reign he stood for a policy of reform but later changed noticeably toward conservatism. During the last two years of his life he was ill, and the administration was taken in hand by his son Charles. The restrictions on agriculture and commerce were relaxed; the guild system was done away with in 1846; the old rules confining trade to the towns were removed. By decisions reached in the *riksdag* for 1844–45 the right to suppress newspapers was definitely abrogated. In 1847 an important poor-law system was introduced. One of the greatest questions of that period was that of communication: railways had to be built, but there were differences of opinion as to the laying down of the main lines through the sparsely inhabited land. In the *riksdag* of 1853–54 it was decided that the main lines should be built by the state, and the direction of the work was placed in the hands of Col. Nils Ericson. Friends of reform concentrated more and more on the demand for a thoroughgoing change in the formation of the *riksdag*, and many proposals were submitted without any of them being accepted. The revolutionary movement which marked the year 1848 on the continent aroused feeling also in Sweden and some street disturbances occurred in Stockholm. The government produced a new scheme of representation, which, however, was rejected by the *riksdag* of 1850. A strong Scandinavian movement manifested itself (especially in Denmark and Sweden, although the Norwegians also took part in it); great meetings of students were held, but no program for the unity of the Scandinavian countries with any real life in it was ever framed. When the Schleswig question led in 1848 to war between Denmark and the German states, a Swedish army was collected together in Skane and troops were carried over to Fyen, in case Jutland should be invaded; but they never had occasion to come into action. During the Crimean War Sweden and Norway maintained neutrality. In Nov. 1855 they reaped the benefit: a treaty was concluded with England and France by which the union states undertook not to cede any portion of their territories to Russia while the two other powers undertook to prevent any Russian efforts in that direction (the November treaty). Side by side with the peace treaty in Paris there was concluded a separate agreement between Russia, France and England in which Russia undertook not to fortify the Aland Islands.

The increasing consumption of spirits, as a result of the right to distil for household needs, called forth anxiety and led to a temperance movement conducted by persons such as Peter Wieselgren, a pastor. Private distilleries were done away with by the *riksdag* of 1853–54 and the distilling of spirits was regulated by the state. Ever since the middle of the 19th century the question of temperance has affected parties.

Charles XV.—The crown prince had conducted the government for two years when he became king under the name Charles XV (1859–72). He was a fascinating man who by his liveliness of mind, personal friendliness and artistic temperament won great popularity, but he lacked the thoroughness and perseverance in work and the seriousness which are called for in a statesman. His undeniable gifts were bound up with an extravagant imagination which in certain situations was a danger. This became most noticeable in the German-Danish war of 1863–64, when he gave the Danes distinctly to understand that they could count on an alliance between Denmark and Sweden-Norway, an idea which had never had the sanction of the state councils of either of the union countries and which was never to be realized. A number of Swedes, however, did enter the Danish army as volunteers.

The social changes which had come about in the life of Sweden necessitated a new form of electoral representation, and increasingly the general feeling was that it must be solved by giving up the division into four estates and that a *riksdag* with two chambers should be founded instead. The minister of justice, Louis de Geer (*q.v.*), took the lead in the matter and the government submitted a bill in the *riksdag* of 1862–63. The new constitution was finally accepted by all four estates in the *riksdag* of 1865–66, and in Jan. 1867 the first *riksdag* of the new kind was assembled. It soon became evident that it was the peasants who had benefited most by the reform: within two years they dominated the second chamber and their party—the so-called Lantmanna party—was a power to reckon with.

Through the influence of the finance minister, Baron J. A. Gripenstedt, Sweden was led more in the direction of free trade, and its treaty of commerce with France in 1865 was an epoch-making event in the development. All duties on grain were removed. The right of trading was extended in 1864. Among more important reforms may be mentioned the criminal law and the maritime law of 1864. The wars which were in progress on the continent caused the *riksdag* to grant large sums for armaments but the government's proposal for a reorganization of the national defenses was rejected.

Oscar II.—After a prolonged illness Charles XV died in Sept. 1872 and was succeeded by his brother Oscar II. The most noteworthy event in the latter's reign was the dissolution of the union with Norway.

The union plans of 1815 were never quite clear, and great doubts had always existed regarding the documents in question and their precise bearing. The Norwegians, apprehensive of Swedish domination, had sought always to give the narrowest possible application to the provisions of the act of union, while the Swedes, generally speaking, sought to give them a wider application, although with increased powers for Norway. The first great crisis arose over the question of the post of *stathallare*, or governor, of Norway. At first this post had been held by Swedes, but as this had invited opposition they were succeeded by Norwegians. In 1859 the *storting* resolved to abolish the post altogether; but in Sweden it was contended that as the post was provided for in the act of union it could not be rejected by Norway alone. The question was shelved for a time, and in 1873 Oscar II sanctioned the resolution of the *storting*. The first great union committee had met in the 1840s and had been followed by several smaller committees and in the years 1865–67 by a great committee which worked out a plan for a new agreement between the two kingdoms. This, however, had been rejected by the *storting* in 1871. The position of the sovereign of the two kingdoms was now becoming extremely difficult, because modern parliamentarianism had progressed much further in Norway than in Sweden and the powers of the sovereign had consequently become much less extensive in Norway. Thus the king had been forced to make continual concessions to the Norwegians. In the year 1835 it had been decided that the premier or another member of the Norwegian government should be called into the Swedish-Norwegian ministerial council whenever questions concerning the foreign affairs of Norway alone or both kingdoms should be under discussion. In the 1880s a dispute arose about this joint ministerial council. From 1891 onward the *storting* demanded Norwegian consulates for Norway. Also, it reduced the annual grant for the court. Because of the protectionist demand of Sweden a Swedish-Norwegian joint law (dealing with reciprocal freedom from customs duties) ceased to exist in 1897, and in 1898 the king ratified a decision of the *storting* to remove the joint union emblem in the upper right-hand corner of the Norwegian flag; it disappeared afterward from the Swedish flag. A small union committee put forward in 1902 a proposal for separate consular services but joint foreign office. Negotiations took place and in 1903 understanding seemed to be in sight. The Swedish plan provided that the foreign minister might be either a Norwegian or a Swede. But from both sides there came charges of breach of faith, and in Norway all parties demanded dissolution of the union. The Swedes were astonished when on June 7, 1905, the *storting* declared the union with Sweden to be dissolved. The *riksdag* acquiesced in the dissolution of the union upon certain conditions, such as that Norway should destroy certain frontier fortresses erected near the Swedish frontier, that the regions adjoining the frontier should constitute a neutral zone without fortifications and military manoeuvres, etc. King Oscar laid down the Norwegian crown on Oct. 26, 1905.

During the first years of King Oscar's reign, however, the question of national defense had been the dominant one, the first

chamber contending for an improved system and the peasant members in the second chamber making demands which could not for a long time be conceded. A number of army organization proposals were rejected, and during the 1880s the question of customs duties caused bitter disputes. The increasing exportation of grain from the United States and Russia together with the strong industrial competition among all countries resulted in a protectionist movement in Germany and France which extended also to Sweden. The second chamber was protectionist and the first in favour of free trade; in 1887 the majority in the first chamber was so small that it would have been possible to bring about a protectionist system by the collective vote of the two chambers. The king then dissolved the second chamber, which returned with a majority in favour of free trade. The *riksdag* of 1888 on the other hand accepted the customs system, as the general election in the autumn of 1887—through a technical mistake in the election of the free-trade candidates in Stockholm—had given the protectionists a small majority. This issue had profound consequences both in the formation of parties in the second chamber and in other respects. New men came forward, the most conspicuous of whom was the landed proprietor E. G. Bostrom, premier from 1891 to 1900 and 1902 to 1905. The question of the national defenses was provisionally settled by the *riksdag's* decisions in the autumn of 1891 (at an extraordinary session) and in 1901. In the latter year the Swedish military tenure established was completely abolished; the training time of the men liable for military service was increased from 90 to 240 days in the infantry and a longer period in the case of the navy and special branches of the army.

At this period new legislation was necessitated by industrial development and the great increase in the number of industrial workers. In 1881 the conditions of labour for children in all factories were regulated and in 1889 a law was passed on providing against injury while at work; the former law was amplified in 1900 by one dealing with the condition of industrial work for women and children. Trade unions were formed and collective agreements governing labour conditions were arranged between employers and workers. In 1889 a Social Democratic party was formed and in the autumn of 1896 Karl Hjalmar Branting was elected to the second chamber as its first Social Democratic member. The Liberals and Social Democrats demanded an extension of the suffrage for the second chamber, but it was not until the severance of the union with Norway had given a strong impetus to a closer national union on new lines that the question came to be decided. The severance of the union led to the formation of the coalition ministry of Christian Lundeberg, a manufacturer, whose task it was to carry out the dissolution of the union. He was followed at the close of the year 1905 by a Liberal ministry with Karl Staaff, a solicitor, as premier. The *riksdag* of 1906 rejected his suffrage bill, and the ministry resigned. Rear Adm. Arvid Lindman succeeded, with a Conservative ministry; he found a way, in 1907, of solving the suffrage question on the basis of universal and equal suffrage (with certain exceptions) together with the democratization of the communal scale of voting and proportional voting for both chambers. Among other important decisions may be mentioned the monopoly in the issuing of bank notes accorded to the Riksbank in 1897, the restriction of the right of companies to acquire land in northern Sweden in 1906, and the part ownership of the state in the Grangesberg company which owned the Lapland iron ore mines.

Gustav V to World War I (1914).—When Oscar II died on Dec. 8, 1907, the crown fell to his eldest son Gustav V. Modest and simple in his character, avoiding needless display, but capable of bearing himself with the dignity required by his position, he proved a good king for a democratic epoch. Reforms were carried through, as, for instance, the laws on civil marriages in 1908 and for the protection of the peasants in Norrland in 1909. In the summer of 1909 the country witnessed a great trial of strength between the industrial workers' trade unions and employers' associations, which culminated in an unsuccessful general strike.

In the autumn of 1911 the election for the second chamber was held with a doubled electorate and the Lindman ministry gave up office. Karl Staaff formed his second ministry. The Lindman ministry had approved a cruiser of a new type but Staaff's government set aside its decision. A movement to cover the costs of its construction by private subscription produced a sum of 17,100,000 kronor, and the ship was built. The people, indeed, had been disquieted by the way in which the Russians were arming in Finland and with widespread espionage by the Russians in Sweden, and new evidence of alarm was forthcoming in Feb. 1914 when 30,000 peasants met in Stockholm to request the king that the whole question of national defense should be handled simultaneously. The king's answer was favourable, and the Liberal ministry (which had passed a new law for workmen's protection in 1912 and introduced old-age pensions in 1913) resigned.

The king commanded the *landshovding* Hjalmar Hammarskjold (*q.v.*) to form a new ministry. K. A. Wallenberg became minister of foreign affairs. The second chamber was dissolved and the *riksdag* reassembled after the election of May 1, 1914. The new government had a majority in the first chamber but not in the second. (K. Hr.)

World War I.—By World War I Sweden found itself more or less cut off from the western world, from which it had bought a large proportion of its food supplies, raw materials and finished goods. The war put an end to some of the party strife that had rent the country, particularly in connection with the strengthening of defense. In due course Sweden declared its neutrality, measures for the reorganization of defense were passed, and Swedish neutrality was preserved all through the war despite external and even some internal pressure by activists favouring one or the other side. At the same time a common policy of neutrality bound the three Scandinavian states together and erased some of the bitter feelings between Sweden and Norway.

At first industry and commerce took an upward swing as a result of large purchases by the belligerents; soon, however, this intensive buying exhausted stocks which could no longer be replenished, and the export of some goods was made subject to licence. At the same time the state confiscated important goods at fixed prices, distributing them by rationing, and took over certain imports. Nevertheless, there was at times extreme shortage of some foodstuffs.

The Hammarskjöld government continued in office until 1917, when it resigned over the supply position. A Conservative ministry carried on until the general elections, which brought considerable gains for the Social Democrats. A Liberal-Socialist coalition under the Liberal Nils Eden took over, and Sweden's most famous Socialist, Hjalmar Branting, entered the government for the first time. The new government solved the supply problem by two agreements with Great Britain, the second one being the so-called *modus vivendi* agreement concluded in March 1918. The Russian Revolution, followed by the German, seriously affected Swedish thought and led to a revival of demands for a democratization of the constitution. As a consequence, a special session of the *riksdag* (*urtima*) passed a radical proposal that included *inter alia* votes for women. One effect of the bill was to make the Social Democrats the strongest party in the *riksdag;* the Conservatives were the second strongest, while the Liberals, who lost some seats, split into two groups in 1923—the National Liberals (Folkfrisinnade) and the Liberals—thereby further weakening their position. A small Communist party and a Farmers' party were also formed.

Another consequence of the Russian revolution, Finland's secession from the Russian empire, affected the Swedish scene. While the government recognized Finland's independence in Jan. 1918, it did not dare grant military aid to the new nation lest this should involve Sweden in the war or lead to difficulties at home—the sympathies of left-wing Social Democrats being with the soviets while a strong bourgeois opinion demanded aid for the tsarists. The government's decision adversely affected Finno-Swedish relations, and Finnish resentment was further increased by the dispatch of a Swedish naval expedition to the Åland Islands in February, when the islands were threatened by a Russian landing. Finnish circles interpreted this action as an attempt to express practical sympathy with an earlier demand by the Ålanders to be absorbed into the Swedish realm. Not until Sweden's calm acceptance of the League of Nations decision in favour of Finland's

retention of the islands did this resentment gradually die down.

The Interwar Period.—The great advance of the Social Democratic party was the most striking development between World Wars I and II. In 1920 the Liberal-Socialist coalition was followed by the first purely Social Democratic government under Branting, but the autumn elections resulted in a small setback for his party, whereupon a "business" ministry of a moderately Conservative character carried on until after the elections of 1921, when Branting formed a new government. This remained in office until 1923, to be followed by a series of short-term governments from the right or from the left, including a Liberal government under Carl Ekman that commanded only 33 votes and nevertheless carried on from June 1926 to the general elections of 1928. During this period the Social Democrats succeeded in passing a bill which greatly reduced armaments. The Conservative ministry which followed Ekman's government was defeated over its proposal to increase the corn duties and another Liberal government took office in 1930. Ekman resigned following the financial failure and suicide of the prominent Swedish businessman, Ivar Kreuger. In the autumn elections of 1932 the Social Democrats and the Farmers made considerable gains and the Liberal government resigned.

In Oct. 1932 Per Albin Hansson formed his first ministry. Its program included strong measures to overcome the depression, aiming however at financial expansion rather than economies. The Social Democratic party was not strong enough to force these measures through the *riksdag*, and an arrangement with the Farmers—the so-called *Kohandel* ("underhand deal")—was concluded. Against the combined votes of the two parties most affected by the depression, the opposition had to yield. Gradually general developments in industry began to justify the government measures, and unemployment began to fall steeply. Apart from a few months in 1934, when the Farmers governed alone, the Social Democratic party—either alone or in coalition with others—remained in office throughout the ensuing period. In the elections of 1934 it nearly attained an over-all majority. The government's policy was always prevention rather than cure of social and economic ills, and the country prospered accordingly. At the same time the feeling of security of tenure that their strong position gave to the Social Democratic governments was reflected in the increasing atmosphere of calm that prevailed in labour relations and led to a standardization of the so-called collective agreements which by 1940 were covering about 1,000,000 workmen.

Sweden shared in the economic effects of the post-World War I crisis. Early in 1922 unemployment rose to 160,000 and was fought by large-scale relief work. By the close of 1922, however, the nadir had been reached; Sweden's recovery kept step with that of the world outside. At the same time the democratization of the country increasingly affected the economic field. Labour had earlier been organized into trade unions and the co-operative movement flourished, but revolutionary ideas no longer prevailed and a policy of "progress by peaceful negotiation" was embarked upon. The eight-hour day was introduced without wage reduction, and despite shorter working hours production increased. State railways were gradually electrified, road traffic motorized and the merchant fleet substantially increased. The production of pulp was aided by improved forestry; agriculture benefited by research on seed selections; and highly developed engineering works produced increasing quantities of goods for export. In addition, Sweden joined the countries which exported capital.

During the depression in the early 1930s an agricultural crisis was followed by one in industry and unemployment assumed unusual proportions, leading to a number of grave labour conflicts. Sweden followed Great Britain in abandoning the gold standard, which relieved the position temporarily; but when the Social Democrats resumed office in 1932 it was still serious and improved only gradually.

After World War I, Sweden supported the League of Nations, prepared even to abandon something of its policy of neutrality. However, the gradual deterioration of the international situation, the advent of Nazi Germany and the failure of the League to save Abyssinia had a sobering effect. Defense once again became a primary consideration, although a law passed in 1936 for the reorganization of the army aimed rather at modernization than at expansion. When the Germans invaded Austria, Hansson proposed immediate increases in defense in parliament, while the League was advised that Sweden proposed to resume its strict neutrality policy. The fate of Czechoslovakia pointed the danger still further. The government declined Germany's offer of a nonaggression pact, unsuccessfully attempted to bring about closer relations with other Scandinavian governments and also tried to co-operate with Finland in a possible defense of the unfortified Åland Islands, which attempt foundered against Soviet opposition.

World War II.—On the outbreak of World War II the Social Democratic government reiterated the country's official neutrality and strengthened defense. Negotiations were opened with Great Britain resulting in a comprehensive war trade agreement in Dec. 1939. After the outbreak of the Russo-Finnish war a coalition government of all parties was formed. "Finland's cause is ours" became the general watchword. The material aid given to Finland was of unparalleled generosity and endangered Sweden's own security, but Finnish requests for regular troops were refused, although volunteers for Finland were helped and encouraged. Allied demands for the transit of British and French troops to Finland were also met with a refusal from Sweden as they were from Norway.

The German invasion of Denmark and Norway isolated Sweden from the west. The German government put heavy pressure on Sweden to allow the transit of troops and armaments; not until after the end of the war in Norway did Sweden enter into the agreement permitting German soldiers on leave and goods, including war material, to pass over certain Swedish railways. The outbreak of the second Russo-Finnish war forced Sweden to a still greater concession. On June 25, 1941, permission for the transit of a whole armed division from Norway to Finland had to be granted. These agreements aroused bitterness and widespread criticism in Sweden and were the subject of sharp Allied protests. The traffic came to an end in the late summer of 1943, after Germany's position had deteriorated and Swedish military strength increased. Until then Sweden had been forced to supply Germany with iron ore and other important materials in exchange for the import of essential goods; now stringent reductions in Swedish exports to Germany were made, and a new war trade agreement concluded with Great Britain and the United States.

Despite its precarious position Sweden succeeded in steering clear of all German attempts to persuade it to participate in the German "new order" policy and all through the war it was a shelter for refugees from German oppression, not only Norwegians, Danes and Finns, but also Balts and Jews of all nationalities. After the war, relief, largely in the form of credits, amounting to about $600,000,000 was extended mainly to Norway and Denmark, and medical supplies, food and clothing were sent wherever needed. The Swedish Red Cross under Count Folke Bernadotte was actively engaged in aiding prisoners of war and had the government's generous support in these activities.

The Postwar Period.—After World War II the Social Democrats dissolved the coalition and governed alone. The first postwar elections in 1948 confirmed them as the strongest party. The unexpectedly slow recovery of devastated Europe, the cumulative effect of unfavourable world trends, Europe's growing economic dependence on the United States and the temporary elimination of Germany from world trade seriously affected Swedish economy. To aid in the revival of Europe, Sweden adopted a generous foreign credit policy. When the expected revival did not materialize a serious economic crisis ensued. Large cuts had to be made in imports and expenditure was reduced, although these reductions never affected social welfare or defense. Gustav V died in 1950 and was succeeded by his son Gustav Adolf (*see* GUSTAVUS VI).

In Oct. 1951 Tage Erlander, prime minister after the death of Hansson, formed another coalition with the Farmers. The economic position gradually improved. The country as a whole blamed the coalition for the high food prices, and the elections of 1952 resulted in slight losses for both government parties.

The government continued to improve the social services and on

Jan. 1, 1955, a compulsory health insurance scheme for the whole nation came into force. On Oct. 1, 1955, the rationing of alcohol came to an end. The general elections in 1956 resulted in further losses for the coalition government. The position in the *riksdag* was then as follows: Social Democrats, 106 (110 in 1952); Liberals, 58 (58); Conservatives, 42 (31); Farmers, 19 (26); Communists 6 (5). The Social Democrats had to make important concessions to the Farmers to preserve the coalition. In Oct. 1957 a national referendum took place on the subject of an additional national pension scheme, in which the plan advocated by the Social Democrats proved victorious. Thereupon the Farmers resigned from the government, and on Oct. 31 Erlander formed a Social Democrat minority government.

Sweden joined the United Nations in 1946. The increasing tension between east and west confronted the government with serious problems, and the proposed formation of the North Atlantic treaty led to much heart searching. Sweden proposed in 1948 a common defense pact to Denmark and Norway. When this failed (largely because the United States was unwilling to supply arms to such an organization), Sweden decided to revert to the traditional policy and not to join the North Atlantic Treaty organization. It was fully understood, however, that only a strong defense could protect such neutrality, and increasing amounts were spent on armaments. In all other respects Sweden supported international cooperation. It joined the Council of Europe and took an active part in the work of the Organization for European Economic Cooperation.

In April 1954 the tercentenary of the first treaty of friendship and commerce between Sweden and Great Britain was celebrated and a British-Swedish chamber of commerce with its headquarters in Stockholm was inaugurated. At the end of 1954 a cyclotron with a capacity of 200,000,000 v. was completed at the Swedish Nobel institute. Relations with the U.S.S.R. and eastern European countries were affected in 1955 by the discovery in Sweden of cases of espionage in which members of the embassies of Communist countries in Stockholm were involved. In March 1956 an agreement between Sweden and Norway was signed under which Sweden was allowed greater facilities for its transit traffic through Norwegian harbours in Trondheim fjord, which would prove useful in time of war. The agreement also provided for the construction of a Swedish oil port in Trondheim fjord. In Oct. 1957 the great Arctic iron ore company, Luossavaara-Kirunavaara, was nationalized at a cost of 825,000,000 kronor.

POPULATION

The population of Sweden is low in comparison with the area of the country (44 per square mile) and unevenly distributed.

Table I shows the distribution of population in 1960 in the administrative districts or counties (*län*), which differ from the former division into provinces (*landskap*).

The population according to the 1960 census (7,495,129) was about four times as large as it had been in 1750 (1,780,000) and twice what it had been in 1850 (3,480,000).

The average annual excess of births was 7.86 per 1,000 in the 19th century, reaching a maximum of 10.39 in the years 1841–60; in the 1930s it had fallen to 2.78, with a minimum of 2.09 in 1935. There was a rise during World War II culminating with 9.57 in 1945. After that it diminished again, being 6.43 in 1950 and 5.17 in 1956.

Emigration, especially to the U.S., increased rapidly from 1860 onward, with a maximum during the period 1881–90 (average 38,000 a year). Then the U.S. legislation on immigration and also the attainment of a comparatively high standard of living in Sweden in the years after World War I caused a decline in the number of emigrants, and in the 1940s there were practically none. In 1956 there were 14,737 emigrants, including 4,258 Swedish citizens.

TABLE I.—*Area and Population*

Län (county)	Area (sq.mi.)	Population 1960 census			
		Urban	Per cent of total	Total	Density (per sq.mi.)
Älvsborg	4,928	152,410	40.6	375,006	76.1
Blekinge	1,173	59,313	41.0	144,468	123.1
Gävleborg	7,614	118,176	40.3	293,070	38.5
Göteborg och Bohus	1,986	484,757	77.6	624,762	314.6
Gotland	1,225	15,626	28.8	54,322	44.4
Halland	1,904	73,068	43.0	170,060	89.3
Jämtland	19,903	24,777	17.7	139,800	7.0
Jönköping	4,436	139,250	48.8	285,271	64.3
Kalmar	4,487	79,408	33.7	235,770	52.5
Kopparberg	11,724	78,849	27.6	285,862	24.4
Kristianstad	2,478	59,125	23.1	256,475	103.5
Kronoberg	3,827	33,268	20.9	158,977	41.5
Malmöhus	1,878	425,595	68.0	625,667	333.1
Norrbotten	40,879	81,655	31.2	261,672	6.4
Örebro	3,492	135,018	51.5	262,239	75.1
Östergötland	4,278	207,438	58.0	357,693	83.6
Skaraborg	3,262	87,466	35.0	250,180	76.7
Södermanland	2,645	135,781	59.7	227,615	86.0
Stockholm (city)	72	808,484	100.0	808,484	11,228.9
Stockholm	2,997	203,072	44.0	461,082	153.8
Uppsala	2,084	90,556	53.9	167,735	80.5
Värmland	7,497	107,233	36.8	291,085	38.8
Västerbotten	22,834	51,029	21.3	239,625	10.5
Västernorrland	9,924	77,202	27.0	285,620	28.8
Västmanland	2,615	132,964	57.2	232,589	89.0
Totals	170,143*	3,861,520	51.5	7,495,129	44.1

*Total excludes 3,522 sq.mi. of large inland lakes not apportioned to any *län*.

The immigrants were at earlier periods considerably fewer, but they exceeded the emigrants during World War I and after 1930. The highest figures after World War II were approximately 33,000 in 1948, 32,000 in 1951 and 30,000 in 1955. Besides the large number of refugees, many immigrants were attracted by the favourable conditions for obtaining employment, and skilled labourers (particularly from Italy and Germany) were offered employment through the intermediacy of the government.

In 1960 there were 3,738,696 male and 3,756,433 female inhabitants. The population is racially more homogeneous than in most other countries. There were in 1950 about 34,000 Finns living in the frontier region and 5,300 Lapps in the far north.

Population is denser in the south than in the north: in 1960 Malmöhus *län* had 333 persons per square mile and Norrbotten *län* 6. The annual excess of births over deaths in 1951–55 was about 40,000 or 5.52 per 1,000. The low birth rate of the 1930s was one of several reasons for expecting the working population to be stationary up to 1960, when the increase in the birth rate that took place during and after World War II began to have its effect upon the labour market.

The urban population was 51.5% of the total in 1960. Up to 1860 this percentage had remained nearly stationary at about 11, growing subsequently with the progress of the industrialization. Stockholm, the capital of Sweden, had in 1960 a population of 808,484, Göteborg 404,349 and Malmö 228,878. Norrköping, Helsingborg, Örebro, Uppsala, Västerås, Borås, Linköping, Eskilstuna and Gävle had each between 50,000 and 100,000 inhabitants. In all, there were 133 towns, 100 of which had more than 10,000 inhabitants.

Religion.—More than 99% of the total population belongs to the Established Church of Sweden, which is Lutheran and has the king as its supreme head. Among the minorities the Jews (about 6,700 in 1950) and the Roman Catholics (20,000) are the most important. There are also certain rather important "free-church movements" (numbering about 400,000 adherents), many of which are recognized within the Established Church. Freedom to leave the Established Church without joining a "foreign religious community" (*i.e.*, without becoming a Jew, a Roman Catholic, a Methodist, Episcopalian or a Swedenborgian) was introduced at the beginning of 1952 but did not seem to bring about any immediate consequences.

With the archbishop of Uppsala as primate, the Established Church of Sweden is divided into 13 dioceses each headed by a bishop. The church parishes number 2,500.

Education.—Public elementary education became free and compulsory in 1842. In 1954 compulsory schooling was increased from eight to nine years. Besides the two old universities in Uppsala (founded in 1477) and Lund (founded in 1668), there are universities in Stockholm and in Göteborg. Stockholm has also special graduate schools of technology, forestry, commerce, dentistry, veterinary science, pharmacy, arts, music, etc.; Göteborg has graduate schools of technology and commerce; Malmö has a graduate school of dentistry; Umeå, in the north of Sweden, has a graduate school of dentistry and one of medicine was established in 1958. For advanced studies in social work and public administration, there are special institutes in Stockholm, Lund and Göteborg.

Self-education is an outstanding feature in Swedish cultural life: nearly 65,000 study circles were in action in 1957, with students numbering about 690,000. Considerable government subsidies are given for this form of adult education as well as for popular lectures. People's colleges, the first of which date from the 1860s, provide a special type of voluntary education for persons about 20 years of age. Organized as boarding schools, many of them are sponsored by political parties, by bodies concerned with the labour market or by popular movements.

In 1956 there were 8,464 primary schools with 816,533 pupils and 41,885 teachers, 142 higher elementary and intermediate schools with 45,346 pupils, 252 secondary schools with 141,684 pupils and 537 vocational schools with 118,724 pupils. There were 26 teachers' training colleges with 4,250 students. In 1956 the four universities had together 16,935 students with teaching staffs totaling 1,433 professors and lecturers. The remaining 11 institutions of higher education had 6,882 students in 1956.

Social Welfare.—About 10% of the national income is used for welfare and social security, including compulsory health insurance, maternity benefits, child allowances, old-age pensions, rent rebates to large families, free school lunches and schoolbooks and equipment. About 29% of the state budget expenditure goes on social security and public health.

Conditions on the labour market are often regulated by voluntary decisions taken jointly by leading organizations concerned (the central body of trade unions, the central body for the professions, certain agricultural organizations and the employers' union). In this way it was agreed in 1946 that "enterprise councils" should be introduced into industry. Working hours, vacations (three weeks' paid holiday), safety arrangements and other provisions for protecting the workers, collective bargaining and rights of association are settled by law.

Traditions and Recreations.—In some parts of Sweden—Dalecarlia, Värmland, Gotland—old customs are well preserved and picturesque peasant costumes still sometimes worn at festivals. Christmas is the main festival of the year. People dance around Maypoles on Midsummer's Eve and light bonfires on the eve of May day. Of later origin are the celebrations for the "queen of lights" (St. Lucia) on Dec. 13.

Special dishes include hard rye bread in flat cakes (*knäckebröd*) and *smörgåsbord*, an hors d'oeuvre consisting of different kinds of snacks (herring, salmon, eel, salads, slices of meat, etc.) and often served at the beginning of the meal with bread and butter and, sometimes, a glass of liquor (*snaps*). In view of the social evils associated with drunkenness prohibition was suggested by the temperance movement in 1910, but was rejected by a plebiscite in 1922.

Ivan Bratt's system of rationing, introduced in 1917, subjected the purchase of liquor to severe control by law. This system was abandoned in 1955, the one remaining regulation being that in restaurants a light meal must be ordered in connection with alcoholic beverages (except wine).

Swedish gymnastics from the time of Per Henrik Ling have had a world-wide following. The National Athletic association, formed by the various clubs, has a total membership of about 600,000. Other favourite forms of sport are skiing, skating, ice hockey, bandy (an ice game with a ball), sailing, rifle shooting and track finding. There are 41 golf courses. Lawn tennis had a special patron in King Gustavus (Gustaf) V and became increasingly popular. Association football is the most popular sport.

GOVERNMENT, JUSTICE AND DEFENSE

Sweden is a limited monarchy, the constitution resting primarily on the Constitution act (*Regeringsformen*) of 1809. June 6, the day of enactment and also the day when Gustavus Vasa entered Stockholm in 1523, is now celebrated as Sweden's national day. The throne is hereditary but may be occupied only by male members of the royal family. The executive and judicial authority is vested in the king alone, but his resolutions must be countersigned by a member of the cabinet (*statsråd*). The cabinet is appointed by the king and is responsible to the parliament (*riksdag*), without the consent of which it cannot act. The government consists of a prime minister (*statsminister*); the heads of the 11 departments of administration, which are justice, foreign affairs, defense, social affairs, communications, finance, church and education, agriculture, commerce, interior affairs, civil services; and three or four ministers without portfolio. Administrative posts are equally open to men and women. Holders of government offices are appointed by the king. Apart from provincial governors and a few others, who are as a rule appointed for a period of six years, Swedish civil servants are undismissable except in case of default and after trial and judgment.

The central administration outside the ministries is on the whole independent of politics, which usually play little part in appointment to government offices. The cabinet shares legislative powers with the *riksdag* and introduces new bills in it; and their members have also the right to introduce new bills. In order to take effect legislative bills must be approved by the government as well as by the *riksdag*. By the 1950s the general tendency in the Swedish political life seemed to be toward increasing the influence of the government, which for the two preceding decades had been based on a majority in the *riksdag*.

The *riksdag* is bicameral. Members of the upper chamber (150 seats), who sit for eight years, are elected by the town and county councils, and one-eighth of their number stands for election every year. The 230 members of the lower chamber are elected every fourth year by direct vote of all men and women over 21 years of age (universal suffrage dates from 1921). Candidates must be 23 years old to be eligible. The two chambers have equal authority and their agreement is required to enact a bill.

Amendments to the constitutional law, in which among other things the freedom of the press is guaranteed, must be decided twice by the *riksdag* and the cabinet in two different sessions with a general election intervening. There are nine standing joint committees for different fields of legislation.

Local Government.—Sweden is divided into 25 administrative districts or *län* (*see* Table I). The chief official of the *län* is the governor (*landshövding*), appointed by the king in council. Under him is the administrative board of the district with executive, fiscal and civil defense functions and control over the "local" police (under the ultimate authority of the ministry of the interior). Whereas these are the local branches of the state administration, there is on the other hand a far-reaching local self-government in the parishes, dealing among other things with health and sanitation, poor relief, education, fire and certain police work. Matters relevant to larger areas are decided upon by the representative bodies of the *län* (*landsting*). An average parish has a few thousand inhabitants; the areas represented by the *landsting* have several hundred thousand. The local units have the right to decide upon their own taxes to raise what money they need.

Justice.—Justice is administered by tribunals of three instances. In the first instance, there are 116 rural judicial circuits (*domsagor*), the court of which (*häradsrätt*) consists of a judge and from seven to nine lay assessors (*nämndeman*), who assist the judge with information and advice regarding the case. If seven out of eight or nine assessors present are unanimously of a different opinion from the judge, they can outvote him; but this seldom occurs. The town courts, called *rådhusrätt*, consist of the mayor (who in Sweden is a judge, not a chief of the local government) and at least two aldermen; they have assessors only in serious criminal cases. Second, there are six courts of appeal (*hövrätter*),

which are established in Stockholm, Jönköping, Malmö, Umeå, Göteborg and Sundsvall. Third, the supreme court (*högsta domstolen*) passes sentences in the name of the king, who is nominally the highest judicial authority. Cases dealing with administration and administrative law are eventually referred to the supreme administrative court (*regeringsrätten*), but there is no court trial of the constitutionality of administrative decisions. After 1948, when legal proceedings were reformed, argument was [in principle] oral rather than written.

Defense.—Sweden's armed forces consist of three services, the army, the navy and the air force. The command of all armed forces is held by the king and, under him, by the supreme commander, who has the defense staff at his disposal, co-ordinates the activity of the three services and directs military planning. Military service is compulsory for all males between 20 and 47 years of age; about 40,000 conscripts become liable every year.

In the army the preparatory training lasts 10 to 11 months (1952), to be supplemented later by three operational training courses each of one month's duration and with an average interval of six years. In wartime the army comprises about 600,000 men mobilizable in a short time. The home guard is an integral part of the army and recruitment is voluntary, its members being mostly drawn from the age groups under 20 or over 47.

The navy, which includes the coastal artillery, consisted in 1957 of 3 cruisers, 23 destroyers and fast frigates, 33 motor torpedo boats, 24 submarines and about 100 small surface vessels. The coastal artillery is responsible for the defense of harbours, anchorages and potential invasion areas. Its permanent installations are as a rule blasted into the rock. The air force in 1957 comprised 50 squadrons, 30 of which consist of day fighters, 3 of night fighters, 12 of attackers and 5 of reconnaissance aircraft. By the middle of the 1950s, transition to jet propulsion was completed, the core being formed by the Swedish J29 ("Flying Barrel") jet fighters. Some wings have Hawker Hunter and De Havilland Venom fighters. Among the attackers is the Swedish Saab design A32 "Lansen," considered to be one of the fastest fighter-bombers in the world. The "Flying Barrel" would in due time be succeeded by the new Saab design, the delta-winged supersonic fighter J35 "Draken."

The armed forces are supported by various voluntary defense associations comprising several hundred thousand men and women; they make increasing use, for example, of the Swedish women's volunteer service. Equipment is to the greatest possible extent designed and constructed by Swedes. Every Swedish citizen between 16 and 65 years of age who does not belong to the armed forces may have to serve in the civil defense, which is trained in peacetime to be responsible in war for first aid, clearing and fire services as well as for protection against chemical and biological warfare. Air-raid shelters were being blasted into the rock in an endeavour to give protection even against atomic bombs.

ECONOMY

An important change in the structure of Swedish economic life took place after the 1870s. In those years about 70% of the population earned its living from agriculture, but in 1950 only 23% did so. During the same period industry increased its proportion from 15% to 41% of the population, becoming in the process the most important source of national wealth. The corresponding figures for commerce and communications are 5% (1870) and 22% (1950).

Agriculture.—Less than 10% of the whole area of Sweden is under cultivation, with the main agricultural regions in the south and around the big lakes in central Sweden; natural meadowland covers about 3%. More than half the land area is covered by forests; the rest is mountainous and barren. Sweden is practically self-sufficient as far as agricultural products are concerned. The yield per acre is high and exceeded by few countries in Europe. Wheat cultivation, through scientific plant breeding, has been extended almost to the Arctic circle and is superseding the cultivation of rye. Sugar beets are grown in southern Sweden and on the islands of Öland and Gotland, the crop being nearly equal to the domestic demand. Nearly 50% of all agricultural income is derived from milk and milk products.

TABLE II.—*Agricultural Production*

Horses	633	497	384	283
Chickens	10,980	14,023	11,654	11,601

After 1930 and particularly after World War II a large-scale mechanization and modernization took place within Swedish agriculture: the number of tractors in use grew from 2,100 in 1930 to 19,100 in 1939 and from 21,300 in 1945 to 107,458 in 1954, when there were, moreover, about 10,000 light tractors; and between 1944 and 1951 there were notable increases in the numbers of combines (from 407 to 6,200), mechanical binders (from 71,000 to 86,900) and milking machines (from 40,000 to 108,000) in use. The government encourages small farms to pool their machinery, and nearly every farmer is a member of the producers' co-operative groups for marketing agricultural products. About 90% of the arable area is privately owned, and not more than 20% of it is held on lease. Of the 414,000 farms, about 75% had in 1944 less than 25 ac. of arable land, while less than 2% had 125 ac. or more. In central and northern Sweden the farms mostly include some forest. The principal aim of Swedish agricultural policy is to further the creation of larger operative units.

Industry.—The bases of Swedish industry are the forests, the iron ore deposits, the water power and the technical skill of the workers. Between 1935 and 1950 the volume of industrial production was doubled (*see* Table IV), and between 1900 and 1950 it grew sevenfold. Small enterprises predominate. By far the greater part of Swedish industry is in private hands. Of the industrial workers only 5% are employed in government-owned factories and 4% in co-operative enterprises; thus privately owned firms employ 91% of industrial workers. The number of factories in 1950 amounted to 17,034 with a total of 663,000 workers,

TABLE IV.—*Industrial Production, 1934–56*
(In 000 metric tons, if not otherwise stated)

Industry	1934	1938	1946	1950	1953	1954	1955	1956

*1951. †1947.

but only 55 factories employed more than 1,000 workers, and only 539 from 201 to 1,000 workers.

Timber and Wood Products.—Forests, mainly pine, cover about 87,000 sq.mi. or more than 50% of the surface area of Sweden. Current annual growth available to the timber industry is estimated at 60,000,000–70,000,000 cu.yd. Cutting and conservation are regulated by law, and large-scale scientific research is conducted by experimental stations and institutes with a view to increasing the yield per acre. One-half the forest area is owned by private persons, one-fourth by companies, one-fifth by the state and the rest by the church and local communities. After the outbreak of World War II the industry was concerned to supply not only the traditional timber, pulp, paper and board but also more valuable products such as rayon, alcohol, plastics, dyes, glue, resins, turpentine, etc.

Iron.—Sweden's iron ore deposits are among the richest in the world. They consist of the long-worked mines in central Sweden (Bergslagen; estimated deposits 220,000,000 tons) and of the later workings in northern Lapland (Kirunavaara, Gällivare, etc.; estimated deposits 2,000,000,000 tons). The domestic iron industry uses mainly ore from Bergslagen, which contains a singularly pure iron. The Lapland mines, the ore of which is phosphorus bearing but rich in iron content (60% to 70%), are worked for export. More than 90% of the output of iron ore is exported; about 17,000,000 tons were exported in 1956. Of Europe's total resources in ore of high iron content, more than 90% is to be found in the Lapland mines. There are also some ore deposits containing gold, silver, copper and arsenic; also zinc ore is mined.

Fuel and Power.—Sweden's coal deposits, which are found only in the south, normally produce not more than 300,000 tons a year, together with firebrick and fire clay, though output was doubled during World War II. Imports of coal and coke were estimated to amount to 7,200,000 tons per year in the 1950s, chiefly from Great Britain, Poland and the German Federal Republic. In addition, approximately 1,000,000 tons of crude oil and 2,000,000 tons of motor and fuel oil were imported. Wood and peat are also used as fuel. But electric power has more and more replaced fuel in homes as well as in industry.

After Switzerland and Norway, Sweden has the world's highest consumption of electricity per person. The installed capacity amounted in 1956 to 6,590,000 kw., including 5,240,000 kw. in hydroelectric plants. The output of energy rose between 1939 and 1957 from 6,030,000,000 kw.hr. to 29,124,000,000 kw.hr., after the harnessing of about half the existing water-power resources. More than half of the electric power is supplied by private companies. The trunk transmission line from Harsprånget in the far north to central Sweden, opened in 1952, first in the world to have a voltage as high as 380,000, has a transmission capacity between two and three times as high as that of lines with a voltage of 200,000.

Foreign Trade.—Sweden's foreign trade is relatively high. Including earnings from shipping, its value in 1952 was about $498 per head of the population, a figure exceeded by only a few countries. This was explained by the growing industrialization of the country's economy, requiring the import of many raw materials and semifinished products, fuel, machinery and chemicals. On the other hand Sweden's own products, such as lumber, pulp, iron ore, high quality steels, ball bearings, etc., were in great demand in the markets of the world. (*See* Table V.)

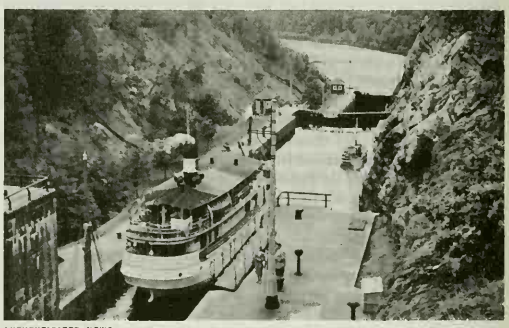
In 1951–54 about 71% of the value of Sweden's total foreign trade was with the European Payments union countries (including 22% with the sterling area), 11% with the dollar area and 18% with the rest of the world. Traditionally the largest buyer of Swedish goods was the United Kingdom (16.5% in 1952). From 1948 to 1951 it was also Sweden's foremost supplier, but in 1952 imports from the German Federal Republic exceeded those from the United Kingdom.

TABLE V.—*Foreign Trade*
(in 000,000 kronor)

Item	1934	1938	1946	1950	1954	1955	1956
Imports (c.i.f.)	1,307	2,087	3,309	6,117	9,192	10,337	11,428
Exports (f.o.b.)	1,303	1,844	2,548	5,708	8,195	8,933	10,047
Balance	−4	−243	−851	−409	−997	−1,404	−1,381

Communications.—More than 50% of Sweden's imports and exports are transported on Swedish vessels. The merchant navy grew considerably in the course of the 20th century. With a gross tonnage of 2,959,000 in 1956, it put Sweden in tenth place among the world's seafaring nations or, according to the relation of the tonnage to the population, in fourth place (after Norway, Great Britain and Denmark). In 1954 more than half the tonnage was engaged in ocean trading, on regular runs to all parts of the world. Sweden is one of the foremost shipbuilding nations. The amount of tonnage launched in 1957 amounted to 673,000 gross register tons, 70% of which was for foreign owners. The canal network is important.

In 1946 the Swedish, Norwegian and Danish commercial airlines were merged to form the Scandinavian Airlines system (S.A.S.) to operate services to North and South America. In 1951 an agreement was signed extending the merger to cover all the operations of the three companies. This merger agreement was made retroactive to 1950. In 1954 the S.A.S. was the first to fly over the north pole.



AUTHENTICATED NEWS

THE LOCKS AT TROLLHÄTTAN ON THE GÖTA CANAL

Sweden possesses a highly developed network of railways, the oldest of which dates from the 1850s. From the beginning the state took an active part in the construction of trunk lines: The total length of the lines amounts to about 10,000 mi. (more in relation to the population than that of any other European country), of which about 40% has been electrified (this portion however accounted for 86% of the total traffic in 1951). An act of parliament of 1939 provided for the gradual nationalization of railways that were still privately owned. Ferries connect the railways with continental lines through Denmark and Germany.

The total length of public roads is about 58,000 mi., to national highways covering 2,700 mi. and provincial highways 12,400. Motor vehicles registered in Dec. 1956 comprised 734,533 passenger cars and 120,615 trucks and buses. The density of population being low, bus lines are naturally of great importance to Sweden.

In 1957 Sweden had 2,312,000 telephones, or 315 per 1,000 inhabitants, which was the second highest proportion in the world. The number of radio licences (2,535,000 in 1956) in relation to the population (345 per 1,000) was surpassed only by the United States. There was no regular television broadcasting until Oct. 1956; the number of television licences was 70,000 in Nov. 1957. There is only one sound and television broadcasting system (Radiotjänst); it is partly state-owned and nonpolitical and carries no advertising in its programs. There are about 250 newspapers, of which approximately 150 are dailies (around 20 appear also on Sundays). Their total circulation is 5,300,000 copies. The Liberal press covers more than half the circulation.

Finance.—The state budget is divided into two parts, the budget of current expenditure and the capital budget, the latter being in principle devoted to government investments, which are covered by national loans. (*See* Table VI.) The gross national product increased between 1938 and 1956 from 11,060,000,000

TABLE VI.—*Current Budgets, 1938–1958**
(in 000,000 kronor)

Item	1938–39	1952–53	1953–54	1954–55	1955–56	1956–57	1957–58†

*Years ending June 30. †Estimates

kronor to 44,445,000,000 kronor (*i.e.*, four times) while the index numbers of cost of living (1935 = 100) rose from 106 in 1938 to 244 in Dec. 1957. The public debt rose between Dec. 1939 and Dec. 1957 from 2,664,289,000 kronor to 19,095,109,000 kronor.

The unit of currency is the krona (plural, kronor). Its exchange rate against the pound sterling was 14.5 kronor = £1 in 1958 (*cf.* 16.92 kronor = £1 before 1946); against the U.S. dollar the rate was 5.18 kronor = $1 in 1958 (*cf.* 3.60 kronor = $1 before devaluation in 1949).

The Swedish credit market is characterized by the multiplicity of types of credit institutions, official, semiofficial and private, among which the distribution of the functions and of the operating fields is not always clearly defined. The Bank of Sweden (1657), which is the oldest national bank in the world, is subordinated to the *riksdag* and not to the government. There were 19 commercial banks in 1958. Two of these, Svenska Handelsbanken and Skandinaviska Banken, held each about one-quarter of the assets of the whole commercial banking system; the third largest Sveriges Kreditbank, holding about one-tenth, is state-owned; two others, Stockholms Enskilda bank and Göteborgs bank, held about one-tenth. Whereas these five have a more or less nationwide network of branch offices, the other commercial banks are regional or local. Savings banks numbered about 450 in 1955, the total of deposits in them amounting to not much less than that in the commercial banks. Special state organizations supervise the activities both of the commercial and of the savings banks. Mortgage loans are advanced by a number of special institutions (for housing, agriculture, shipping, etc.).

B.; F. BN.)

SWEDENBORG, EMANUEL (1688–1772), Swedish scientist, philosopher and theologian, one of the greatest and most learned men of his country, was born in Stockholm on Jan. 29, 1688, the second son of Jesper Swedberg, who was later appointed bishop of Skara. The family assumed the name of Swedenborg when it was ennobled in 1719. Emanuel was educated at Uppsala university; and after completing his course there he traveled abroad for five years (1710–14), visiting England, Holland, France and Germany in pursuit of scientific and mechanical knowledge. At that period his chief interests were mathematics and astronomy, and he was cordially received by John Flamsteed and by Edmund Halley. He was anxious to see and to hear Sir Isaac Newton, whose work he studied avidly, but there is no evidence that the two met. Swedenborg's inventive and mechanical genius flowered early, and his plans, practical and otherwise, ranged from a method of finding terrestrial longitude by the moon to new methods of constructing docks and even to tentative suggestions for the submarine and the airplane.

On returning home, Swedenborg began to publish a scientific periodical, *Daedalus hyperboreus* (Uppsala, 1716–18). Charles XII of Sweden was interested in the venture but would provide no funds, and after six issues the periodical was obliged to cease publication. Charles, however, in 1716 appointed Swedenborg assessor extraordinary to the Royal College of Mines, in which office, and later as assessor, he devoted himself for 30 years to the development and improvement of Sweden's metal-mining industry. But he continued to seek fresh knowledge in this and other spheres and from time to time traveled in Europe and in England in pursuit of learning in physics, chemistry, mechanics and philosophy. He had already published in 1718 the first work on algebra in the Swedish language; and in 1721 he published at Amsterdam his *Prodromus principiorum rerum naturalium* in which he offered a geometrical explanation of the phenomena of chemistry and physics. In 1734 he published his *Opera philosophica et mineralia*, 3 vol. (Leipzig), the first volume of which constitutes his *Principia rerum naturalium*. In this work, though without the facts that later scientists have demonstrated, he reached by inductive argument conclusions that are close to the theories of modern nuclear physicists. The first product of the infinite is conceived of as "pure motion" or conatus-to-create, and the subsequent creation is a complex of motion. The atom is composed of vortex particles, but these are compositions of motions more interior. The pattern strongly resembles the pattern of the atom as described in terms of nucleus and electrons. In the same work and from the same general principle Swedenborg suggested the nebular hypothesis to account for the formation of planets.

During the next ten years Swedenborg was engaged in anatomical and physiological studies. As he had sought to find the "soul" of creation in pure motion, he now sought to understand the soul of man and to find it in its own kingdom, which is the body. He published *Oeconomia regni animalis*, 2 parts (London and Amsterdam, 1740–41), and *Regnum animale*, 3 parts (The Hague, 1744–45). Although in this field of study he made many experimental investigations, he used them only sparingly, because he recognized the danger of trusting too much to his own observations and of "originating a whole series of inductive arguments from my particular discovery alone. . . . I therefore laid aside my instruments . . . and determined rather to rely on the researches of others than to trust to my own" (introduction to *Oeconomia*). In both works he therefore begins each section with numerous quotations from the accepted experimental anatomists and then proceeds to reason upon them. Gustaf Retzius acknowledged that Swedenborg had been the first to indicate the real nature of the cerebrospinal fluid. In the *Oeconomia* Swedenborg also showed, long before any other physiologist, that the motion of the brain synchronizes with that of the lungs and not with that of the heart and circulatory system; and he discerned the relationship between various regions of the cerebral cortex and corresponding motor regions of the body.

It is, however, in the field of theology that the name of Swedenborg is chiefly known, and the circumstances in which he turned to theological studies have tended to obscure his reputation as a great scientist and philosopher. He asseverates that his entry upon this new study was in response to a divine vision and call; that his spiritual senses were opened so that he might be in the spiritual world as consciously as in this world; and that the long series of exegetical and theological works that proceeded from his pen constituted a revelation from God for a new age of truth and reason in religion. Furthermore, he held that this new revelation of the Lord was what was meant by the second advent. Because of his otherworld experiences Swedenborg has often been regarded as a spiritualist "medium," yet it may be observed that the normal idea of mediumship is reversed, the man being admitted into the spiritual world, not the spirits into the material world. Nor can he properly be classed among the mystics, for in his dry, matter-of-fact accounts of the spiritual world and in his acutely reasoned theology there is little in common with mysticism. His manner is still that of the scientific and philosophic investigator.

Philosophically he had consistently recognized the infinite as the indivisible power and life within all creation, and he had never wavered in his belief that this infinite was God. In his theology he maintains the absolute unity of God in essence and person. A trinity of persons in one God is, he says, an impossibility of thought, but since God is the Divine Man there is necessarily in Him, as in every person, a trinity of love, wisdom and activity; and in God these are infinite and divine. It was this God who came into the world as Jesus Christ for the redemption and salvation of men. The inmost soul of Jesus was the Divine itself, the one God; yet, in order that there might be an intimate contact of God with fallen man, the Divine assumed from Mary a human nature comprising all the planes of human life. But during the course of Jesus' life on earth, by resistance to every possible temptation and

by living to their divine fullness the truths of the Word of God, all that was actually from Mary was expelled, and the planes of human nature were "glorified" or made divine from the indwelling Divine Soul and became the divine embodiment of that soul. The Trinity is therefore a Trinity in one Person, the Father being the originating Divine itself, the Son the manifestation and embodiment of that Divine and the Holy Spirit the outflowing life and activity of the "Divine Human."

In rejecting tripersonalism Swedenborg necessarily rejects the orthodox conceptions of redemption. The redemption of mankind was a deliverance from the domination of evil. The hells, which are the communities of the spirits of evil men in the spiritual world, were aspiring to enforce themselves upon men's minds, destroying their freedom to discern between truth and falsity and therefore between good and evil. By admitting into Himself their temptations and by complete resistance to them, Jesus broke their power; and the inflowing of the Inmost Divine into the human plane thus perfected interposed an eternal and infinitely powerful barrier between the hells and men. The "Divine Human," to which belongs "all power in heaven and on earth," stands forever between man and the forcible imposition of themselves by the hells. Man is thus free to know and obey the truth. His salvation depends on acceptance of and response to divine truth.

Swedenborg, accepting that all creation has its origin in the divine love and wisdom, accepts that all created things are necessarily forms and effects of specific aspects of that love and wisdom and so "correspond," on the material plane, to spiritual realities. The material realm is one of effects whose causes are spiritual and whose purpose is divine. The Scriptures, he says, are written according to this principle of "correspondence," which becomes the key to unlock their spiritual teaching. In *Arcana coelestia*, 8 vol. (London, 1749–56), he presents a detailed interpretation of Genesis and Exodus according to the principle of correspondence; and in the posthumously published *Apocalypsis explicata*, 4 vol. (London, 1785–89), he does the same with the Book of Revelation and incidentally with many other parts of the Scriptures. The theological teaching in his works was collated as a systematic theology in *Vera Christiana Religio* (Amsterdam, 1771). The philosophy of the creation and maintenance of the universe is dealt with in *Sapientia angelica de Divino Amore et de Divina Sapientia* (Amsterdam, 1763) and *Sapientia angelica de Divina Providentia* (Amsterdam, 1764). Swedenborg's best-known work is probably *Heaven and Hell* (*De Coelo et ejus mirabilibus, et de inferno*, London, 1758).

Swedenborg died in London on March 29, 1772, and was buried in the Swedish church. In 1908 the Swedish government had his body removed to Uppsala cathedral.

Swedenborg neither preached nor founded a church. The New Jerusalem Church, founded by a few disciples about 1784, remains small but has branches throughout the world. The Swedenborg society was founded in London in 1810 to publish his works.

Swift, *Swedenborg, the Man and His Works* (London, 1883; new ed., 1932); C. S. Sigstedt, *The Swedenborg Epic* (New York, London, 1953); also the *Transactions* of the International Swedenborg congress, 1910 (London, 1911). (A. Cm.)

SWEDISH LANGUAGE AND LITERATURE.

The Swedish language is about 1,000 years old. It began in the viking age when the Scandinavian national states first emerged, and the characteristic features which separate the modern Scandinavian languages developed. Old Swedish was originally spoken in Sweden itself—excepting the most northerly and southerly parts and certain western areas—in the coastal belts of Finland, Estonia and Livonia, with their islands, and in certain parts of Russia conquered by vikings, who here and there maintained themselves until the 13th century. In the modern world it is used by about 7,750,000 people; *i.e.*, by 6,750,000 living in Sweden, by 370,000 Swedish-speaking Finns (less than 10% of the Finnish population) and by about 630,000 Swedish immigrants in North America.

The ultimate ancestor of Swedish is Common Norse, one branch of the family of Germanic languages commonly divided into three groups: (1) East Germanic (Gothic); (2) West Germanic (Dutch, English, Frisian and High German); and (3) North Germanic—*i.e.*, Scandinavian (Swedish, Danish, Icelandic, Norwegian and Faroese). Swedish with Danish form the East Scandinavian group; the three others are West Scandinavian. Modern Swedish, though still more inflected than contemporary Danish or Norwegian, has dropped a great many of the inflections current, in some instances, into the 18th century (*see* below). The verbs are divided into four conjugations, the nouns into five declensions and the gender of these nouns into common (*den*) and neuter (*det*). Only two case forms have survived for the nouns: nominative and genitive. The genitive is formed by adding *s* to the nominative both in the definite and indefinite form, both in singular and plural; thus *dag, dags, dagens, dagar, dagars, dagarnas*. As an example of the changed forms compare singular nominative definite *dagen* with the classical Old Swedish *daghr-in, dagens* with *daghs-ins, dagarna* with *dagha-nir*, dative form *daghum-in* and accusative *dagha-na; cf.* Anglo-Saxon *daeg* (modern English "day"), German *Tag* and Danish *dag*. The adjectives are declined according to gender, number and definite and indefinite forms. Examples of the sound mutations between Danish and Swedish are Danish *gade* and Swedish *gata* ("street"), Danish *bog* and Swedish *bok* (book).

Runes.—Runes are the oldest form of Swedish writing. About 2,500 runic inscriptions survive from the earliest period of *fornsvenska* (*c.* A.D. 800–1225); most of them are found in Uppland and date from the 11th and 12th centuries. Cut in stone, often put into metrical form, they commemorate the genealogy and achievements of the dead. The most remarkable stone, Rökstenen in Östergötland, dates from the 9th century and is unique in the length and interest of its inscriptions, written in seven different types of script. Other interesting inscriptions have been found in Hälsingland, including the Nalstadsten, in the so-called "staffless" script. Unfortunately, save for the runes, nothing of the earliest Swedish literature has survived, but it is likely that there was some sort of literary culture akin to that of Iceland.

CLASSICAL PERIOD OF OLD SWEDISH

We possess a greater and more reliable knowledge of Swedish after the religious orders (first Cistercians, later Dominicans) had introduced the Latin alphabet, originally for the transcription of religious texts, and had founded schools to assist their missionary work. The earliest examples of Latin letters are on coins of the time of Olaf Skötkonung (993–1022). Then follows the classical period of Old Swedish (*c.* 1225–1375), with the beginnings of a native literature, inferior in quality and volume to that of Iceland. The purest Swedish language of this time is highly inflected, uses simple constructions and is surprisingly free from foreign influences, the few Greek or Latin loan words generally relating to church matters. Nouns have four cases, the suffixed article is inflected, and there is also much inflection of verbs.

The oldest extant manuscript in classical *fornsvenska* is not a translation from Latin, but part of a native legal code, *Västgötalagen*, compiled in the 1220s. A number of such local codes survive; *e.g.*, *Östgötalagen*, *Dalalagen*, records of provincial laws set down by a magistrate and preceding the lawbooks like *Upplandslagen* (1296) and *Södermanslagen* (1327), compiled on official initiative and ratified by the king. These codes are forceful and full of concrete images; they often use alliteration and solemn prose rhythm to make their pronouncements more memorable. They offer the happiest examples of the vernacular literature in their age, and culminate in Magnus Eriksson's *Landslag* (*c.* 1350) and in a similar work, *Um styrilsi kununga höfdhinga* (*On the Conduct of Kings and Princes*), probably written about 1330 for the guidance of the same ruler. This reflects both Swedish respect for law and the influence of Christian culture, even of scholasticism.

Dialects.—Differences of dialect occur in the runic inscriptions and in these legal codes, as in other products of this old literature. Two main groups of Swedish dialects, each comprising a number of subdivisions, have been classified: the Svea group, including the northern areas, Uppland, Hälsingland, etc., and parts of Öster-

götland; the Göta group comprising Värmland, Västergötland, parts of Småland, etc., and more recently the south Swedish provinces, which till long after the Reformation were Danish-speaking regions. The archaic language of Gotland is excluded from this classification. Even in the period of Old Swedish it differed so fundamentally from the Swedish of the mainland that *forngutniskan* ranked as a separate language. It may be studied in about 200 runic inscriptions and a 13th-century *Gutalag*.

Religious and Secular Literature.—The importance of Christianity in the cultural development of Sweden is immense, yet the new religion prevailed only gradually, and pagan rites existed well into the middle ages and in remote districts for much longer. Slowly, too, the primitive society of viking times was replaced by a more complex organization, dominated by the nobility and the clergy, patrons and providers of literature. Latin eclipsed the vernacular as a literary medium, and this helps to explain the derivative nature of mediaeval Swedish letters. Thus, though the poetry of chivalry reached Sweden, the Swedish writings inspired by chivalrous ideals were mere free adaptations of French or German originals. *Eufemiavisorna*, the best-known of these works, three verse romances translated anonymously between 1303 and 1312, are in rhymed doggerel, a metre again employed in the chronicle romance *Erikskrönikan*, a record of the fortunes of the Swedish kings between 1220 and 1320, probably compiled soon after the latter date. An anonymous and hybrid work, it is the most powerful single poem of mediaeval Sweden.

Only in religious writing, from among unknown Latin hymn writers, compilers of legendaries, etc., do a few personalities emerge. The Dominican Petrus de Dacia (*c.* 1235–89), with his *Vita benedictae virginis Christi Christinae*, is often considered the first Swedish author; Bishop Brynolf Algotsson (*c.* 1250–1317) is the first distinguished Latin hymn writer in Sweden. But both were overshadowed by St. Bridget (*c.* 1302–73), the founder of Vadstena monastery. Only the Latin version of her text, the *Revelationes*, survives, first printed at Lübeck in 1492.

YOUNGER OLD SWEDISH

The downfall of the Folkunga dynasty and the death of Bridget mark the end of a period. Under the impact of the stormy *Unionstiden*, with its foreign rulers, the character of society and of language changes, and we get the *yngre fornsvenskan* (*c.* 1375–1526), a language diluted with German loan words—mostly technical and commercial terms—and with Danicisms, which sheds a number of its inflections. At the same time there occurs a standardization of the literary language, largely under the influence of Vadstena *kloster*, the main focus of culture in Sweden until the Reformation. Both Latin and German affected the syntax of the vernacular.

Literature.—The insecurity of these times had an adverse effect on literature, yet with the growth of a reading public, translations and adaptations multiplied. They included versions of books of the Bible, a long doggerel romance of Alexander (*c.* 1380) and a political allegory, the poem *Schacktavelslek* (*The Game of Chess, c.* 1465). In the rhymed chronicles, too—*e.g.*, *Karlskrönikan, Sturekrönikan* and *Lilla Rimkrönikan* (which treats events up to 1520)—political interest prevails. Of greater literary value are the Latin hymn *Rosa rorans bonitatem* by Bishop Nicolaus Hermanni (1326–91) and the two short lyrics *Frihetsvisan* and *Trohetsvisan* that have earned for Bishop Thomas Simonsson (*c.* 1380–1443) the title of the first Swedish national poet. Yet the most accessible genre of Swedish mediaeval letters—the *folkvisor* (ballads or folk songs)—is anonymous and undated. The oldest probably go back to 1300, but they were not transcribed until much later. Though outnumbered by the Danish, and often deriving from Danish or Norwegian sources, many of the Swedish *folkvisor* have a strong and lasting appeal.

EARLY NEW SWEDISH (c. 1526–1700)

As Gustavus Vasa's accession (1523) and the breach with Denmark mark the beginning of modern Swedish history, so the printed translation of the New Testament (1526) is considered to usher in *den äldre nysvenskan*. Yet in both this work and the complete translation of the Bible (*Gustav Vasas Bibel*, 1541), conservatism is visible in the word order and in the maintenance of inflections already shed in less solemn contexts. The translators excluded the Danicisms typical of the *kanslispråk* (clerical style), but were much influenced by Luther. Still, a standardized literary *rikspråk* does grow up during this period, and an increase of interest in grammar, vocabulary and orthography is visible during the 17th century. The centralization of government in Stockholm and the influence of the court affected both the written and spoken norms, while Swedish intervention in the Thirty Years' War led to the assimilation of many foreign words.

Literature of the Reformation.—The Reformation stimulated no immediate growth of letters; such books as appeared were still mainly religious and didactic. Closely involved in the Bible translations were Olaus Petri (*c.* 1493–1552), his brother Laurentius (d. 1573), the first Lutheran archbishop, and Laurentius Andreae, at one time Gustavus' chancellor. Of these, Olaus seems to have had the most robust personality. After studying at Wittenberg he returned to Sweden full of reforming zeal, which won him the king's favour; later, his independence and critical spirit nearly cost him his life. His vigorous approach is revealed in his published sermons, in his hymn translations, in catechism and in legal writings; it is shown, too, in his *Swensk krönika*, the first authentic historical work in Sweden, far surpassing the official chronicle of Peder Swart. Petri may have written the biblical *Tobie comedia* (1550), the first complete extant Swedish play.

Uppsala university (founded 1477), closed in 1517 because of political unrest, was not revived until late in the 16th century and became a focus of learning and letters only in the 17th century. Johannes Rudbeckius, one of the first Swedish educators, was associated with it, and so was Johannes Messenius (1579–1636), who wrote several mythical-historical plays, such as *Disa* (1611) and *Signill*. Although formless and crude these plays enjoyed great popularity, as did Magnus Olai Asteropherus' more successful *Tisbe* (1610), the first nondidactic drama in Swedish.

In the first half of the 17th century literature remained limited in scope and quantity. Some Latin poetry, the sermons of Rudbeckius and a handful of plays—including *Judas Redivivus* (1614) by J. Rondeletius, *Gustaf den förste* by A. Prytz and some comedies by J. Chronander—are worth recording. A unique contribution, however, was made by the vagrant adventurer Lars Wivallius (1605–69), whose lyrics, many of them written in prison, reveal a feeling for nature new to Swedish poetry.

Literature of Stormaktstiden, 1650–1730.—With its intervention in the Thirty Years' War and the ensuing military triumphs, Sweden established itself as a European power (*Stormakt*). This led to a great development of national pride and culture that is revealed in the literature of this epoch. The first and probably the best work is Georg Stiernhielm's allegorical epic *Hercules*, written about 1647 in vigorous hexameters. Stiernhielm (1598–1672) was the greatest literary figure of the 17th century. His followers include the two brothers Columbus, of whom Samuel (1642–71) was Stiernhielm's secretary and wrote *Odae sueticae* and the prose *Målroo eller Roomål*, a charming collection of anecdotes which illumine Stiernhielm's character. A rival to Stiernhielm was the unidentified "Skogekär Bergbo," whose *Wenerid* (1650; published 1680) was the first sonnet cycle in Swedish. Another unsolved problem of this period is the authorship of the epithalamium *Bröllopsbeswärs Ihugkommelse*, a realistic poem long attributed to Stiernhielm. Several of Stiernhielm's admirers, including Urban Hiärne (1641–1724), formed a coterie at Uppsala in the 1660s. Hiärne led a troupe of student actors who in 1665 performed his play *Rosimunda* before the young Charles XI. He also wrote lyrics and the pastoral *Stratonice* (1666–68), the first Swedish "psychological" narrative.

Stiernhielm was eager to revive old Swedish words and eliminate foreign loans. Columbus also demanded a more vigorous, flexible language for prose and poetry, as did "Skogekär Bergbo" in *Thet swenska språketz klagomål*. National pride and religious feeling are combined in the works of the bishops Haqvin Spegel (1645–1714) and Jesper Swedberg (1653–1735) father of Emanuel Swedenborg. Both were hymn writers and ardent philologists. Spegel

wrote a religious epic, *Guds werk och hwila* (1685) and sponsored the plan for a new hymnbook which appeared in 1695 and became the poetry book of the Swedish people, and, like *Gustav Vasas Bibel,* of lasting influence. Even Lars Johansson (1638–74; pseudonym "Lucidor") was represented therein. This poet, though one of the most attractive lyricists of the period, otherwise stands apart from the general development; some of his poems have survived in a posthumous collection, *Helicons blomster.*

At Uppsala meanwhile the scholar Petrus Lagerlöf (1648–99) worked on poetics and attempted to impose classical standards, and O. Verelius (1618–82) edited and translated Icelandic sagas. Olaus Rudbeckius (1630–1702), a man of vast energy and learning, became interested in Verelius' work on antiquities and enthusiastically developed the theory that Sweden was the lost Atlantis and had been the cradle of western civilization. These theories he launched in a massive work. *Atland eller Manhem* (1679–1702), deliberately written in Swedish to prove that the language was suited to scientific purposes. The work was translated into Latin as *Atlantica* and attained European fame.

Rudbeckius had encouraged Hiärne's actors. Lagerlöf now sponsored a second Uppsala company, which moved to Stockholm in 1686 and acted in Lejonkulan (the "Lion's Den"). This became Sweden's first regular (though short-lived) theatre. The "Lejonkula" plays show little dramatic talent but reveal how Lagerlöf's teaching had produced more correct verse.

Baroque tendencies are found in the work of some late 17th-century poets, notably Gunno Eurelius (ennobled as Dahlstierna; 1661–1709), who dedicated his elaborate *Kungaskald* (1697) to Charles XI. J. Runius (1697–1713) expresses a Christian stoicism found among the Swedish people during the disastrous early decades of the 18th century. J. Frese (1691–1729) is a gentler and more intimate poet; his lyrics and hymns contain some of the emotional pietism that became a feature of 18th-century thought.

MODERN NEW SWEDISH (c. 1700 AND AFTER)

Den yngre nysvenskan is the form of Swedish now current; it is intelligible (except for a few words and expressions) to a modern reader without commentary. Olof von Dalin's *Then swänska Argus* is the first important literary work in this form. During the 18th century several grammars and dictionaries contributed to standardization, and the Swedish academy (founded 1786) was given the task of "working for the purity, strength, and sublimity of the language." It issued a grammar in 1836, but its dictionary (*Svenska Akademiens ordbok*) did not appear until the 1890s. Meanwhile, C. G. af Leopold of the academy had published (1801) a treatise on spelling involving the radical Swedicizing of foreign words, especially the numerous French loans absorbed during the previous century. Few changes in orthography occurred during the 19th century; the most recent spelling reform was made in 1906. The importance of the written language increased after 1850; it was much affected by the press (dating, in a modern sense, from the foundation of L. Hierta's *Aftonbladet* in 1830), and the gap between the spoken language of educated men, modelled on the written norm, and the printed word was gradually reduced. An important aspect of this tendency was the speech usage whereby the singular form of the verb was employed with a plural subject; this became the norm of the press in the 1940s.

Literature, 1730–1809.—After the death of Charles XII (1718) and the collapse of his empire, a more utilitarian attitude to life and letters gradually set in. Olof von Dalin (*q.v.*) (1708–63) is the outstanding popularizer of the new ideas of French and English Enlightenment. Educated at Lund university (founded 1668), he later went to Stockholm and began to publish, anonymously, *Then swänska Argus,* modelled on Joseph Addison and Justus van Effen, almost the first serious journalistic venture in Sweden. In forceful, supple prose, Dalin ridiculed the foibles of the capital. *Sagan om hästen* (*The Story of the Horse,* 1740) showed his mastery of allegorical satire, occasional verses and songs his skill as a lyric poet. He became a court poet and favourite and a member of Queen Lovisa's Vitterhetsakademi (1753). In spite of the increasing secularization of literature during *Frihetstiden* (1718–72), the drama still lacked life; neither Count Karl Gyllenborg's comedy *Den svenske sprätthöken* (*The Swedish Fop,* 1737) nor O. Celsius' tragedy *Ingeborg* has more than historic interest.

With the second phase of the Enlightenment, marked by the deepening influence of France, are associated Hedvig Charlotta Nordenflycht (1718–63), Count Gustaf Creutz (*q.v.*) (1731–85) and Count Gustaf Gyllenborg (1731–1808). Fru Nordenflycht published in 1743 *Den sörjande turturdufvan* (*The Sorrowing Turtledove*), in which she lamented the death of her husband in short lyrics. Creutz was a more sophisticated personality. He wrote little, devoting his life after 1763 to diplomacy, but his few writings, of which *Atis och Camilla* is the most important, reveal a mastery of form and Epicurean views. Gyllenborg did not achieve his friend's formal elegance, but his best poems, *Världsföraktaren* and *Vinterkväde,* have nobility and feeling for nature.

Prose—particularly the novel—developed more slowly. The first genuine novel was *Adalrik och Giöthilda* (1742–44) by J. Mörk and A. Törngren, showing the influence of the Icelandic sagas and of Madeleine de Scudéry. But the raciest prose of this period is found in J. Wallenberg's *Min son på galejan* (*My Son on the Galleon,* 1781), a humorous, realistic diary of voyages on an East Indiaman. The most notable historian was S. Lagerbring, and J. Ihre enriched historical philology with his *Glossarium sviogothicum* (1769). The only two 18th-century Swedes with European reputations were scientists: Carl von Linné (Linnaeus; *q.v.*) (1707–78) and the versatile and mystic Emanuel Swedenborg (*q.v.*) (1688–1772). Linné's work at Uppsala much enhanced the prestige of the university, and his Swedish travel books were later praised for their understanding of nature and freshness of style.

The Gustavian period (1771–1809) takes it name from the brilliant Gustavus III (1746–92) and his intolerant son Gustavus IV. Gustavus III saw himself as the patron of art and letters; at his court he collected the best writers of the time, and by founding the Swedish academy he gave them official status. He was especially interested in drama and opera; thanks to his patronage a proper theatrical tradition was begun and the leading authors—often against their will—had to produce texts for performance. Gustavus himself sketched out some of these works, of which the opera *Gustaf Vasa,* thanks to Johan Kellgren's verses, has survived longest. The comedies of the Gustavian era were modelled on the French; the tragedies were pseudoclassical.

Johan Henrik Kellgren (*q.v.*) (1751–95) was the greatest academic poet of this epoch and the arbiter of taste. In his best poems, such as *Den nya skapelsen* (*The New Creation*), thought and emotion are fused. In *Stockholmsposten,* the main organ of literary opinion in the capital, Kellgren used his polemical wit against Thomas Thorild (1759–1808), the truculent champion of individual genius, who wrote a long poem, *Passionerna* (1781), but is chiefly remembered for his polemical prose. After Kellgren's death the controversy was continued by C. G. af Leopold (1756–1829), who still imposed pseudoclassical standards on the academy and applied them in his rhetorical odes and his plays. Johan Gabriel Oxenstierna (1750–1808) did his most original work in 1770–74 while a diplomat in Vienna; *Skördarne* (*The Harvests*) and *Ode till Camilla* reveal an elegiac, pre-Romantic feeling for the beauty of nature. Unfortunately he revised these poems before publishing them. Bengt Lidner (1759–93) was a follower of Thorild but showed much more poetic inspiration than Thorild in his play *Erik XIV,* his opera *Medea*—both lyrical rather than dramatic in tone—and in his most successful work, the ode *Grevinnan Spastaras död* (1783). The influence of both Milton and the Bible may be traced in his use of language.

Carl Mikael Bellman (*q.v.*) (1740–95) stands apart from the conflicting ideals of his time. A poet and musician, he fused his gifts in the lyrics of *Fredmans epistlar* (1790) and *Fredmans sånger* (1791). His combination of stylized realism with humour and the most delicate sense of language and rhythm is unique in Swedish. He is the greatest Swedish lyricist of the 18th century.

The dissertation *Om upplysning* (*On Enlightenment*) by Nils

von Rosenstein, the first secretary of the academy, nobly expressed the highest ideals of the Gustavian epoch; and various memoirs, by G. G. Adlerbeth, G. J. Ehrensvärd, Count Fredrik Axel Fersen, Duchess Hedwig Elizabeth and others, evoke the witty but artificial atmosphere of Gustavus III's court and illustrate the development of prose. Gustavus IV did not encourage literature; however, the energetic Anna Maria Lenngren (1754–1817), wife of *Stockholmsposten's* editor, wrote some of her best verse satires between 1795 and 1800, many of her anonymous shafts being aimed at aristocratic foibles. The sentimental idylls of F. M. Franzén (*q.v.*) (1772–1847) also belong to these years; they are full of a pre-Romantic idealism imbibed from German and English sources and later toned down under pressure from the academy.

LITERATURE, 1800–70

The Romantic Movement.—The loss of Finland in 1808, the deposition of the king and the new constitution of 1809 all greatly affected Swedish literature, for out of them an ardent national spirit emerged as one of the motifs of Swedish romanticism. The teaching of B. Höijer (1767–1812), admirer of Immanuel Kant and F. W. J. von Schelling, at Uppsala laid the basis for the idealism which soon became the core of Swedish romanticism.

Then the impact of Goethe and Schiller and of the German Romantics was felt, and Swedish romanticism became as much dominated by German culture as the previous era had been by French. Student societies became the focuses of the new movement, and the periodicals issued by them and their adherents—*e.g.*, *Polyfem* (1809–12) and *Fosforos* (1810–13)—attacked the academy. *Fosforos*, from which the Fosforister took their name, played an especially important initial role in the controversy between the old school and the new during 1810–20; in it Per Daniel Amadeus Atterbom (1790–1855), the most gifted poet of the Fosforister, first revealed his talents in his *Prolog*. V. F. Palmblad, publisher and prose writer, led the practical polemics at Uppsala; L. Hammarsköld, with J. C. Askelöf and C. J. Livijn, carried on the fray at Stockholm, while J. D. Valerius and P. A. Wallmark championed the old school, as for a time did J. O. Wallin, who later became the greatest hymn writer of the century (hymnbook of 1819).

Meanwhile another society, Götiska Förbundet, had been founded in Stockholm in 1810, with the object of raising the moral tone of society by study of the heroic, "Gothic" past. Erik Gustaf Geijer (*q.v.*) (1783–1847), one of the founders, suggested the publication of a periodical, and the first issue of *Iduna* consisted largely of his own poems, *Vikingen*, *Odalbonden*, etc. Most of Geijer's poetry, including the first Swedish translation of Shakespeare (*Macbeth*), was written before 1816. Esaias Tegnér (*q.v.*) (1782–1846), professor of Greek at Lund, also contributed to *Iduna*, though he refused to engage in literary controversy, and P. Ling (1776–1839), too, was associated with it.

A brief golden age of Swedish letters occurred in the 1820s. Atterbom published his most remarkable work, the verse drama *Lycksalighetens Ö* (*The Isle of Bliss*) in 1824–27; here, in often obscure but beautiful language, he expressed his philosophy in the allegory of Astolf and Felicia. His other verse drama, *Fågel blå* (*The Blue Bird*), was never finished, and his later years were devoted to a lyric cycle called *Blommorna*, to university work and to *Svenska Siare och skalder* (1841–55), which in a sense laid the foundations of literary history in Sweden. In 1820–25 Tegnér published *Frithiofs saga*, an epic on an Icelandic theme; this became the most popular poem of the first half of the century, and Tegnér, poet, orator and letter writer, who combined Gustavian wit and sense of form with idealism, was the greatest personality of the age. Erik Stagnelius (1793–1823), a complex and brilliant writer, published his *Liljor i Saron* in 1821 and his verse drama *Bacchanterna* in 1822, but most of his work appeared posthumously. Though influenced by the Romantics, Stagnelius held aloof from them and died in deliberately sought isolation.

A number of minor Romantic writers should be mentioned—*e.g.*, A. Törneros (1794–1839); P. Elgström (1781–1810); S. Hedborn (1783–1849), author of several attractive hymns and ballads and of an autobiography, *Minne och poesi;* A. Afzelius (1785–1871), collector of folk songs (*Svenska folkvisor från forntiden*, 1814–16); and E. Sjöberg (Vitalis).

The Romantics cultivated verse rather than prose, though Palmblad certainly contributed something to prose with his long short story *Amala* (1817) and his novels, including *Familien Falkenswärd*. Malla Montgomery Silfverstolpe's *Memoarer* (published 1908–11) gives a naïve picture of the Romantic circle at Uppsala. Geijer's cumbersome historical works—*Svea Rikes Häfder* (1825), etc.—do not reveal his stimulating personality, but *Minnen* (*Memories*) of 1834 are full of the fresh charm of his poetry.

The Coming of Realism.—The most complex personality among the later Romantics was Karl Jonas L. Almqvist (*q.v.*) (1793–1866), who combines an extravagant imagination, as in *Drottningens juvelsmycke* (*The Queen's Jewel*), with the realism which is increasingly prominent in his works after 1836. Almqvist, a master of prose style, was at his best in the long short story (the *novell*); of his works in this genre *Det går an* (1839), an outspoken attack on marriage, foreshadows Strindberg's method of raising problems for debate. Almqvist was enormously productive and versatile; most of his works were published in the volumes of *Törnrosens bok* (1832–51). Meanwhile the realistic novel had made some headway. F. Cederborgh (1784–1835) wrote *Uno von Trasenberg* (1809–10) and *Ottar Tralling*, light-hearted satires on life and manners; but the novel as an accepted genre was really established by Fredrika Bremer (*q.v.*) (1801–65), whose "sketches from ordinary life" appeared from 1828. Her novels, *Grannarne*, etc., have dated considerably, but were formerly very popular in both Europe and America. Sofie von Knorring (1797–1848) wrote novels principally about aristocratic families, and the very popular Emilie Flygare-Carlén (1807–92) produced a long series of stories, including *Rosen på Tistelön* (1847), usually dealing with life on the west coast.

Realism, then, made only slow headway, in spite of the social consciousness of the liberal paper *Aftonbladet* and the example of the great Finnish-Swedish poet J. L. Runeberg (*q.v.*). The literature of the 1840s and 1850s is mainly an aftermath of romanticism, though the critic B. E. Malmström imagined that he opposed this movement. His elegy *Angelica* (1840) had kinship with the graceful but insipid poetry of his contemporary C. V. Böttiger and the older K. A. Nicander. There was a fresher feeling about G. Wennerberg's *Gluntarne* (1847–50), songs about Uppsala student life, but there is nothing new in them. The movement known as Scandinavianism produced a good deal of verse: C. V. A. Strandberg (*Talis Qualis*, 1818–77) was the fieriest poet of this type. Later he did excellent translations of Byron. O. P. Sturzen-Becker (*Orvar Odd*, 1811–69) was a versatile writer with talents in verse and the short story (*Samlade Arbeten*, 1861–62). Popular reading was provided by August Blanche (1811–68), particularly in the successful *Bilder ur verkligheten* (1863–65), which depicts Stockholm life with humour and vivacity. He also wrote popular dramas. Frans Hedberg (1828–1908) held the field at the Royal theatre with pompous historical plays such as *Bröllopet på Ulfåsa*. The quasi-historical novels of M. J. Crusenstolpe (1795–1865), a brilliant and unscrupulous polemical writer, were much appreciated in their day. The most influential historian was A. Fryxell (1795–1881), with his *Bilder ur svenska historien;* and the dominating philosopher was the idealistic C. Boström (1797–1866).

Poetic realism became the official program of Signaturskalderna (the "Pseudonym Poets"), a small group of the 1860s influenced by the Norwegian critic L. Dietrichson. They included C. D. af Wirsén, E. Bäckström and P. Wikner, but only Count C. Snoilsky (1841–1903) had sufficient temperament and poetic gift to carry out the program. Some of Snoilsky's best work is found in *Dikter* (1869) and *Sonetter* (1871). Meanwhile Wirsén had established himself as the conservative literary critic, and from his post as secretary of the academy he launched formidable opposition against all innovators, including Snoilsky. A. V. Rydberg (*q.v.*) (1828–95) exemplifies this rather uneasy transition from idealism to naturalism even more patently than does Snoilsky. Novelist,

poet and critic, he began as a radical journalist and ended as a professor and as author of the philosophical *Dikter* (1882–89). His most important early work was the ideological novel *Den siste Athenaren* (1859), and his treatise *Bibelns lära om Kristus* (1862) had considerable influence through its attack on the narrow orthodoxy of the Swedish Church and prepared the way for scientific rationalism.

LITERATURE FROM 1870

Strindberg.—Four influences combined to free Swedish literature from its petrifying conventions: English thought in the writings of Charles Darwin, Herbert Spencer and J. S. Mill; French naturalism as taught and practised by Émile Zola; the drama of the Norwegians Henrik Ibsen and B. Bjørnson; and the criticism of Georg Brandes. Modern Swedish literature begins with the work of Johan August Strindberg (*q.v.*) (1849–1912), for the modern drama dates from his *Mäster Olof* (1872) and the modern novel from his *Röda rummet* (*The Red Room*, 1879). By his originality, his mastery of prose and dialogue, his great energy and the influence of his work and personality on Swedish, not to say European, literature he is by far the greatest writer Sweden has yet produced.

The 1880s.—Strindberg overshadowed all other writers of the 1880s. G. af Geijerstam (1858–1909), author of *Erik Grane* (1885) and of several other novels and short stories, longed to lead his age, but could not do so. A. M. Edgren-Leffler (1849–92), later duchess of Cajanello, wrote a number of stories called *Ur livet* (*From Life*) in which she satirized conventions adversely affecting women. The more gifted Viktoria Benedictsson ("Ernst Ahlgren," 1850–88) died—by her own hand—before she had fulfilled her promise; she too, but more boldly, was concerned with the position of women in society. Her stories, *Från Skåne* (1884), have lasted better than her novels, *Pengar* and *Fru Marianne*, and reveal how much regional characterization had entered into the new style of literature. With her was associated Axel Lundegård (1861–1931), who soon turned his talents to the historical novel. Alfhild Agrell (1849–1923) wrote her best stories about Norrland. Regional poetry was written by A. U. Bååth (1853–1912) of Skåne; it was surpassed in beauty and originality by the work of another Skåning, Ola Hansson (1860–1925), novelist, critic and poet. Hansson's early poems (*Notturno*, 1885) and his sketches, *Sensitiva Amorosa* (1887), reveal the boldness in imagery and the interest in psychological nuances which are more typical of the next decade.

1890–1910.—Though, except for the work of Strindberg, little of lasting value was achieved in the 1880s, it must be remembered that the generation just discussed accustomed the public to the debating of problems in literature. The reaction against utilitarianism was begun in 1888 by Verner von Heidenstam (1859–1940) with his volume of verse *Vallfart och vandringsår* (*Years of Pilgrimage and Wandering*). Heidenstam's later poetry (*Dikter*, 1895, and *Nya Dikter*, 1915), with his historical tales *Karolinerna* (*King Charles's Men*) and *Folkungaträdet* (*The Tree of the Folkungs*), won him the Nobel prize in 1916. Although much of his work now seems precious and dated his short contemplative lyrics are very fine. Oscar Levertin (1862–1906), stimulated by his friend Heidenstam's example, wrote poetry full of rich colours and the lore of the past (*e.g., Legender och visor*, [1891]); these and other poems show his affinity with the pre-Raphaelites, his knowledge of French symbolism and his awareness of his own Jewish heritage (*Kung Salomo och Morolf*). His criticism published in *Svenska Dagbladet* and elsewhere did much to mould contemporary taste. Gustav Fröding (1860–1911), too, was encouraged by Heidenstam; the title of his first volume of verse, *Guitarr och dragharmonika* (*Guitar and Concertina*) shows the two different strains in the poet, melancholy and gay, which constantly intermingle and out of which he wrested such original music. Despite the threat of madness he managed to publish four more collections of poems before his reason finally gave way, in 1898, by which time he had established himself, especially with *Stänk och flikar* (*Rags and Splashes*), as the greatest Swedish lyric poet since Bellman.

With Fröding, who was from Värmland, regionalism entered into neo-Romantic poetry, and with the work of Erik Axel Karlfeldt (1864–1931) Dalarna came into its own. Karlfeldt's mature poems, such as *Fridolins visor* (1898), *Fridolins lustgård* (*Fridolin's Garden*, 1901) and *Flora och pomona* (1906), reveal his individual strength and the richness of orchestration which he could give to Swedish. He especially loved describing the beauties of autumn, and his erotic poetry is full of the symbolism of country life. He was posthumously awarded the Nobel prize.

Meanwhile Selma Lagerlöf (1858–1940) had developed the prose tale. Her long series of novels and short stories, beginning with *Gösta Berlings saga* (1891), reached an international public; she was, indeed, the first Swede to win the Nobel prize for literature (1909). She often used old Värmland tales for material, though one of her best novels, *Jerusalem I* (1901), is set in Dalarna. Like Karlfeldt but unlike Fröding she is a traditionalist. Per Hallström (1866–1960) is a more skilful writer of short stories than of novels; like Lagerlöf, he did his significant work before 1910 (*Briljantsmycket, Thanatos, De fyra elementerna*). His pessimism led him to depict the futility of human passions, often against a mediaeval or Renaissance background. Romantic, too in his love for the skerries, was Albert Engström (1867–1940), story writer, cartoonist, founder of the popular humorous paper *Strix* and one of the most beloved of Swedish writers. Tor Hedberg, son of Frans Hedberg (*see* above), began with the style of the 1880s; his most lasting work was in the tragedy *Johan Ulfstjerna* (1907) and in the lyric.

Both Hjalmar Söderberg (1869–1941) and Bo Bergman (1869–) had links with the rationalism of the 1880s and with the aestheticism of the 1890s, yet both stand apart from the neo-Romantics. Both, like Strindberg, loved Stockholm, which perpetually recurs as the setting of their works. Söderberg's forte was the short story (*Historietter*), in which his psychological subtlety and irony are happily combined; but his novels, including *Martin Bircks ungdom* (1901) and *Doktor Glas* (1905), have an appreciation of mood and an awareness of the faults of contemporary society which make them unique in Swedish fiction. Söderberg, especially, is one of the masters of Swedish prose. Bergman also achieved memorable short stories (*Drömmen*, 1904; *Skeppet*, 1915; etc.), but his real medium was the lyric; he developed and refined his talent in a series of collections from *Marionetterna* (1903) to *Riket* (1944). Like Söderberg, he is a passionate enemy of hypocrisy and brutality, but his characteristic tone is subdued realism.

1910 Onward.—From the beginning of the 20th century industrialization, the growth of the press and the spread of education increasingly influenced letters. The reading public continued to grow, and the volume of writing similarly increased, a marked feature being the development of the novel, with which are associated Gustaf Hellström (1882–1953), Ludvig Nordström (1882–1942), Elin Wägner (1882–1949) and Sigfrid Siwertz (1882–). Hellström's work as journalist took him to the continent and to the United States, and long residence in England greatly influenced him. His irony and careful realistic detail emerge in his best-known novel, *Snörmakar Lekholm här en idé* (*Lacemaker Lekholm Gets an Idea*), set in a small provincial town. Siwertz is a more elegant stylist—like so many Swedes he began as a lyricist—and a decisive influence upon him was the philosophy of Henri Bergson, reflected in *En Flanör* (1914). His weightiest works are the family saga *Selambs* (*Downstream*, 1920), a novel of Stockholm during World War I, and *Jonas och Draken* (1928); he is also a skilful writer of short stories. Nordström came from Norrland, and his birthplace—Härnösand—is perpetuated in his work as "Obacka." Overflowing with vitality and gifted with keen but grotesque humour, he did some of his best work in *Landsorts-bohème* (1911) and *Planeten Markattan* (1937), but his most satisfying productions are the short stories in *Fiskare* (1907), *Obackabor* (1921), etc. Elin Wägner was an ardent pacifist and feminist; her horror of militarism is shown in her novel *Släkten Jerneploogs framgång* and her feminism in many of her witty short stories. Her most powerful work is the peasant novel *Asa-Hanna* (1918).

The outstanding novelist of the second decade of the 20th century is Hjalmar Bergman (1883–1931). Gifted with a fantastically vivid imagination and restlessly energetic, Bergman wrote a long series of stories many of which are set in "Wadköping" (his native Örebro) and its surroundings, others in Italy. In *Loewenhistorier* (1913), as in other works, Bergman depicts an irrational, impulsive, unsuccessful hero, in *Farmor och Vår Herre* (*Thy Rod and Thy Staff*) one of the dominating female personalities who fascinate him. The satire *Markurells i Wadköping* (*God's Orchid*, 1919) and *Swedenhielms*, one of the few living Swedish comedies, are his most widely known works. Bergman's witty dialogue and rapid characterization, and his inventiveness, both tragic and burlesque, make him one of the most original of Swedish writers, and as dramatist the only native successor to Strindberg.

Meanwhile the "proletarian" novel had been developed—not always by working-class writers—by G. Hedenvind-Eriksson (1880–), M. Koch (1882–1940) and I. Lo-Johansson (1901–), who is particularly concerned with the miseries of the *statarens* (farm labourer's) life. There is particularly harsh and telling criticism of working-class life in *Lars Hård* and other stories by Jan Fridegård (1897–). V. Moberg (1898–) wrote both realistic and historical novels of peasant life. The autobiographical element, strong in many of these writers, and their contemporaries, is evident, too, in the works of Agnes von Krusenstjerna (1894–1940). In her novel cycles (*e.g., Tonyböckerna* and *Fröknarna von Pahlen*) she describes her own aristocratic and upper-middle-class environment, and analyzes a degenerate and perverted psychology. Her works constituted a new departure in Swedish literature.

The greatest Swedish writer of this period is undeniably Pär Fabien Lagerkvist (1891–), who won the Nobel prize in 1951. He was a vital force in literature after World War I and influenced both form and

content. His anguished search for a personal philosophy recalls Strindberg; it is the basis of plays such as *Himlens hemlighet* (1919) and *Han som fick leva om sitt liv* (1928). His best lyrics, such as *Hjärtats sånger*, combine intensity of feeling with subtle rhythm, and his stories have visionary power (*Bödeln, The Hangman*, 1933) and an elemental simplicity, as in *Barabbas* (1950).

Both Eyvind Johnson (1900–) and Harry Martinson (1904–) were self-educated proletarians who turned more and more to experiment with form. Johnson's best work was probably his autobiographical *Romanen om Olof* (1934–37). Martinson wrote both poetry and prose but achieved his most striking effects in prose, in *Kap Farväl* (*Cape Farewell*) and in *Vägen till Klockrike* (1949). Writers of great popularity, too, were Olle Hedberg (1895–), a witty novelist of middle-class life, F. Nilsson-Piraten (1895–), a Skåne humorist, and his fellow-Lundensian Frans G. Bengtsson, author of the historical-humorous novel *Röde orm* (1941–45) and a masterly essayist. Of the youngest authors, Stig Dagerman (1923–) showed particular promise in his play *Skuggan av Mart* (1948).

Many other names occur in connection with the development of lyric poetry. V. Ekelund (1880–1949) developed the dithyrambic form to a high pitch of perfection, then turned to aphoristic prose; A. Österling (1884–) and others became poetic realists; Dan Andersson (1888–1920) developed the ballad; B. Sjöberg (1885–1929) and Karin Boye (1900–41) made the lyric a vehicle for their personal conflicts, Boye's contribution being outstanding. Bertil Malmberg, Hjalmar Gullberg and Johannes Edfelt were among the most successful of modern poets. G. Ekelöf (1907–) wrote effective surrealist verse; and of the "generation of the '40s" (*fyrtiotalisterna*) E. Lindegren and K. Vennberg may be mentioned.

Henrik Schück (1855–1947), with his emphasis on the historical approach to literature, was the father of modern Swedish criticism. Levertin, A. Blanck (1881–1950) and M. Lamm (1880–1950) were his most distinguished pupils.

SWEELINCK or SWELINCK, **JAN PIETER** (also known as JAN PIETERSZOON) (1562–1621), Dutch organist and composer, was probably born at Amsterdam, although his family came from Deventer. It has been persistently stated that he was a fellow pupil with Giovanni Gabrieli and Leo Hassler of the great Andrea Gabrieli in Venice, but this was disproved by F. H. J. Tiedeman in the *Vereeniging voor Nederlandsche Muziekgegeschiedenis* (Amsterdam, 1876). Sweelinck was the son of the organist of the Old church, Amsterdam, and lived in Holland from about 1577 onward. At a date not later than 1581 he was appointed organist to the Old church, his father having died in 1573, and this post he held until his death on Oct. 16, 1621.

A complete edition of his works, edited by Max Seiffert with prefaces, was brought out by Breitkopf and Härtel in 1894–1901.

SWEET, HENRY (1845–1912), English linguist, who was among the first to emphasize the importance of physical, articulatory considerations in historical sound change, was born Sept. 15, 1845, at London, and was educated at King's college (London), Balliol (Oxford) and Heidelberg. He combined competence in historical linguistics with strong interest in the emerging science of phonetics, and a Readership in Phonetics at Oxford (1901) was created especially for him. Sweet died at Oxford on April 30, 1912.

His publications on history and sounds of English, on general phonetics and editions of Old and Middle English texts include: *Handbook of Phonetics* (1877); *New English Grammar* (1892–98); *History of Language* (1900); *Anglo-Saxon Reader* (1908); and *Sounds of English* (1910). His *Collected Papers* were edited by H. C. Wyld (1913). (E. PM.)

SWEET ALYSSUM (*Lobularia maritima*), the ever-popular little white-flowered (sometimes violet), fragrant, half-hardy perennial of the mustard family that is usually grown as an annual. It is wide-spreading on the ground, with branches rising 6 to 12 in., and numerous small flowers distributed in lengthening racemes. It occurs in both large and small forms, some with white-edged leaves and some with double flowers. It is an excellent edging plant that blooms over a long season. (J. M. BL.)

SWEETBREAD, a popular term for certain glands of animals, particularly when used as articles of food; these are usually the pancreas, called stomach sweetbread by butchers, and the thymus, or neck sweetbread. The term is also sometimes used to include the salivary and lymphatic glands. *See* LYMPH AND LYMPHATIC SYSTEM; PANCREAS.

SWEETBRIER (*Rosa eglanteria*), a tall, stiff-stemmed rose, called also eglantine, native to Europe, widespread in Great Britain and extensively naturalized in eastern North America. The erect, somewhat branching stem, armed with stout hooked prickles, grows usually from five to eight feet high. It bears fragrant leaves, of five to seven leaflets, and solitary white or pinkish flowers, one to two inches across. While the sweetbrier is infrequently grown for ornament, various hybrids with other roses are in cultivation. *See* ROSE.

SWEET CLOVER, or MELILOT, the common name for plants of the leguminous genus *Melilotus* comprising about 20 species, native of southeastern Europe and Asia Minor. They are annual or biennial, erect herbs with three-parted leaves of usually small narrow leaflets and small yellow or white flowers borne in slender axillary clusters (racemes). Most of the species contain coumarin, resulting in a sweet odour and bitter taste.

Biennial white sweet clover (*M. alba*), biennial yellow sweet clover (*M. officinalis*) and the bitter clover (*M. indica*), a winter annual adapted only to the southern and southwestern U.S., are of agricultural importance for pasture, soil improvement and hay in the U.S. and Canada. The first two species have become widely naturalized throughout the U.S. and Canada, while bitter clover is widely scattered in the western U.S. *M. suaveolens*, a yellow-flowered species, is grown in a limited way in the southern prairies of Canada, and occasional plants of *M. altissima* have been collected in the eastern states. Several varieties have been developed such as Madrid for the corn belt, Erector for the Great Plains and Willamette for the northwest.

See U.S. Department of Agriculture, *1948 Yearbook of Agriculture*, p. 360 (1948). (E. A. H.; N. TR.)

SWEET CORN: *see* CORN; VEGETABLE.

SWEET FERN, a common name applied to the genus *Comptonia* of the wax myrtle family, also known as the sweet gale family. The genus contains a single species, *C. peregrina*, and the variant asplenifolia, sweet-smelling deciduous shrubs up to five feet, with finely cut alternate leaves and inconspicuous flowers in catkins, fairly common in sandy or rocky soils in eastern North America. (J. M. BL.)

SWEET FLAG: *see* ACORUS CALAMUS.

SWEET GALE (*Myrica gale*), a shrub of the family Myricaceae, called also gale, sweet willow, bog myrtle and Dutch myrtle, widely distributed in the north temperate zone. It grows usually from two to four feet high, with numerous twiggy branches; narrow, short-stalked, fragrant leaves; inconspicuous, unisexual flowers, borne in short spikes, and small, waxy-resinous, drupelike fruits attached to the persistent flowering bracts. The sweet gale occurs throughout the northern U.S. and Canada and on bogs and moors in the British Isles.

ROCHE

SWEET GUM FRUIT CLUSTERS (LIQUIDAMBAR STYRACIFLUA)

See WAX MYRTLE.

SWEET GUM (*Liquidambar styraciflua*), a handsome North American tree of the witch hazel family (Hamamelidaceae), called also red gum, liquidambar (*q.v.*) and bilsted, found from Connecticut to Missouri and southward to Florida and Mexico. It has a straight trunk, sometimes 140 ft. high and 5 ft.

in diameter, with rough bark, corky-winged branches, large, deeply lobed leaves, and drooping, spiny, globose, capsular fruiting heads containing winged seeds.

The hard reddish-brown wood is known to the lumber trade as red gum or satin walnut. The tree yields liquidambar, called also copal balsam, a fragrant gum resin very similar to the storax produced by *L. orientalis* of Asia Minor.

SWEET PEA, *Lathyrus odoratus,* a hardy annual climbing herb of the pea family (Leguminosae) commonly grown outdoors in the cool temperate regions of the world, especially North America and Europe. The sweet pea is a native of Italy, and hundreds of varieties have been developed under domestication. It is one of the most widely used commercial cut flowers because of its excellent durability and the ease with which the plants can be grown in greenhouses.

The fragrant flowers have an unusual colour range: from pure white through cream and various intermediate shades to deep orange; from pink to deep scarlet; and from blue shades to dark purple. In the home garden, sweet pea is often used as a climber in dense rows up to six feet tall or, especially in the dwarfed nonclimbing forms (var. *nanellus*), as a colourful compact border. The plants are frost resistant. In mild climates, seeds may be planted in the late fall about ½ in. deep and 2 in. apart in rich garden soil for growth during the cool winter and for very early spring bloom. In less mild climates, seeds should be similarly planted in early spring after severe frosts are over and the soil can be properly worked.

These sun-loving plants are usually mulched to conserve soil moisture during their growth. (R. C. R.)

SWEET POTATO (*Ipomoea batatas*), a food plant of the family Convolvulaceae (*q.v.*), a native of tropical America, widely cultivated in tropical and the warmer temperate climates. It is a tender perennial grown as an annual in regions where frost occurs. The stems are long, trailing, sometimes short, with entire to palmately lobed leaves of quite variable shape. The flowers, borne in cymes in the axils of the leaves, are funnel shaped, tinged with rose-violet or pink, and are similar in size and shape to those of the common bindweed. The edible part is the much enlarged tuberous root, varying in shape from fusiform to oblong or pointed oval. Root colours range from white through cream to orange, and occasionally purple inside, and from light buff to brown or rose, copper and purplish red outside. The solids of the root consist largely of starch and the orange-fleshed varieties are high in carotene.

The sweet potato rarely produces flowers under common cultural conditions in latitudes higher than about 35°, and produces no seed above about 30° except under special cultural treatment. The seeds produce plants that are unlike the parent plant, therefore the sweet potato is propagated vegetatively by sprouts arising from the roots, or by cuttings of the vines. Seeds, however, are produced commonly in the field in the tropics. They have a very hard seed coat that may retard germination as much as a year, unless the seed coat is nicked or abraded, after which the seeds germinate promptly.

The sweet potato is now widely grown in the United States, in tropical America, the warmer islands of the Pacific, in Japan, and after about 1930 its culture increased rapidly in the U.S.S.R. It is best adapted to light, friable soils such as sandy loams and sandy soils, producing excessive vine growth and small yields or irregularly shaped roots on very rich, heavy soils. At least four to five months of warm weather are required for large yields. In Japan the crop long has been grown for drying and for manufacture of starch and alcohol. In the United States it is grown only for food.

In the United States the sweet potato is propagated usually by bedding the roots close together in sand or light soil in a hotbed heated by manure, by flues or electricity, about four to five weeks before the frost-free date. The sprouts which emerge are pulled from the roots and transplanted to the field about 1 to 1½ ft. apart on ridges 8 to 12 in. high, 3 ft. apart, after the weather and soil have become warm. The roots are harvested mostly about the time of the first frost in autumn since cold soils cause them to deteriorate. The crop responds well to heavy applications of chemical fertilizers low to medium in nitrogen and high in phosphorus and potash. Heavy applications of animal manures or green manures are conducive to the formation of elongated, irregular roots and to root surface injury by scurf, a fungus disease. If the roots are to be stored, they should be placed in the storage house immediately upon harvesting, at a temperature of 85° F. and a relative humidity of 85% to 90% which is maintained for a week to ten days. Then the temperature is lowered to 50°–55° where it is kept as long as the roots are in storage. The "curing" period at high temperature and humidity is essential to hasten the healing of wounds caused in harvesting, thus reducing danger of loss from decay.

The eating quality—and also the market quality and storage life—are greatly improved by curing. If diseases are controlled, roots that are properly cured and stored remain in good edible condition six to seven months.

The sweet potato is very susceptible to several diseases, control of which requires great care in field and storehouse sanitation and management, seed-stock treatment with disinfectants, and crop rotation.

In the United States the principal producing states are ordinarily Louisiana, North Carolina, New Jersey, Virginia, South Carolina, Mississippi, Texas and California. (V. R. B.)

SWEET SHRUB, a common name for *Calycanthus,* a genus which comprises three or four species of deciduous North American shrubs, noted for their sweet-smelling chocolate-coloured flowers, so fragrant in fact that they are variously called sweet shrub, sweet-scented shrub, strawberry shrub and sometimes merely shrub. One species, *C. floridus,* native from Virginia to Florida, is known as Carolina allspice; another, *C. fertilis,* is found from Pennsylvania to Georgia and Alabama; while a third, *C. occidentalis,* occurs in California. All of these are cultivated for their fragrant blossoms and their value as ornamental shrubs. (J. M. Bl.)

SWEETSOP (Sugar Apple; *Annona squamosa*), a small tree or shrub of the family Annonaceae. It has thin oblong-ovate leaves, solitary greenish flowers and a yellowish-green fruit, resembling a shortened pine cone, with a tubercle corresponding to each of the carpels from the aggregation of which it has been formed. The fruit is three to four inches in diameter and contains a sweet creamy-yellow custardlike pulp. Native of the West Indies and tropical America, it has been widely introduced into the eastern hemisphere and is much prized as a fruit. *A. muricata* is the soursop (*q.v.*). *A. reticulata* is the custard apple (*q.v.*), and *A. glabra* the alligator apple.

SWEET WILLIAM, *Dianthus barbatus,* an old-fashioned garden favourite of the pink family (Caryophyllaceae) and one of the most widely cultivated of all the 80 species of *Dianthus* grown in gardens. A relative of the carnation (*q.v.*), it was first introduced into cultivation about 1575 and has since been grown throughout the temperate world. The original European plant and some modern forms are still grown as perennials, but nearly all the finest modern varieties are best treated as biennials. Some strains bloom from seed in a single season and are grown as annuals.

ROCHE

SWEET WILLIAM (DIANTHUS BARBATUS)

Sweet william, 12–20 in. high, has flat opposite leaves lanceolate to ovate-lanceolate in shape, and a stem slightly swollen at the joints. The flowers, borne in a profuse flattish cluster (corymb), have toothed petals that are red, white-dotted or white-striped toward the slightly bearded base. The plant is variable as to colouring, especially in some modern varieties.

Among the many horticultural varieties are excellent scarlet and pink strains that come true from

seed and double-flowered strains which usually do not seed true. Another sort, known as auricula-eyed, has white- or pale-centred flowers with a rim of contrasting colour on each petal.

Seeds of the biennial sort are best sown in June, then potted for carrying over the winter in a cold frame. Many biennials and all the perennials often persist from self-sown seed. (N. Tr.)

SWELLENDAM, a municipality of Cape Province, South Africa, third oldest settlement in the Cape. It is 192 mi. by rail from Cape Town. Pop. (1960) 4,896 all races, 2,511 white. It was earmarked for settlement by Van Imhoff in 1745 and laid out along the Koringlande, a tributary of the Breede, in a fertile valley below the Langeberg mountains. The Drostdy (now a museum) and, across the river, the church—the third to be built in South Africa outside Cape Town—were begun in 1746. Swellendam was the centre of a magisterial district which stretched to the Gamtoos river and until 1786, when Graaff-Reinet was created, it was the frontier outpost of the Dutch East India company's rule. Early English travelers tended to discount it as a small village, but in the 18th century it became a flourishing commercial centre with wainwrights, blacksmiths and traders to serve the farmers when they trekked in from the frontier. The closing of the frontier outpost affected Swellendam, and economic as well as political reasons lay behind the revolt of 1795 (*see* Cape of Good Hope). After the first British occupation (1795–1803) the development of Graaff-Reinet (1786) and the creation of smaller districts both east and north buffered Swellendam from frontier impacts, and its links with Cape Town improved. It was hard hit by the emancipation of the slaves (1834), but continued to be a thriving community, mainly based on farming with a wide variety of crops, viz., wool, oranges, wheat, barley and tobacco. (W. A. Ml.)

SWETCHINE, MADAME (1782–1857), Russian mystic, whose maiden name was Soymanof, was born in Moscow, and under the influence of Joseph de Maistre became a member of the Roman Catholic Church in 1815. In the following year she settled in Paris, where, until her death, she maintained a famous salon remarkable no less for its high courtesy and intellectual brilliance than for its religious atmosphere. Though not physically beautiful, she had a personality of rare spiritual charm.

Her *Life and Works* (of which the best known are "Old Age" and "Resignation") were published by M. de Falloux (2 vol., 1860) and her *Letters* by the same editor (2 vol., 1861).

SWETE, HENRY BARCLAY (1835–1917), English Biblical and patristic scholar, was born at Bristol on March 14, 1835, and educated at King's college, London, and Caius college, Cambridge. He was ordained in 1858, and became dean of Caius college in 1865. In 1877 he accepted the college living of Ashdon, Essex, and in 1882 was made professor of pastoral theology at King's college, London. In 1890 he succeeded B. F. Westcott as regius professor of divinity at Cambridge, retiring with the title of emeritus professor in 1915. He died at Hitchin on May 10, 1917.

Swete's works on Biblical texts are of great importance. In 1887 he published the first volume of his edition of the Greek text of the Old Testament, completing the series in 1894; in 1898 the Greek text of the Gospel of St. Mark with notes and introduction; and in 1906 that of the Apocalypse of St. John. He was the editor of *Cambridge Theological Essays* (1905), *Cambridge Biblical Essays* (1909) and *Essays on the Early Church and Ministry* (posthumous, 1918). His historical and critical works include *The Apostles' Creed in Relation to Primitive Christianity* (1894); *Church Services and Service Books Before the Reformation* (1896); *Patristic Study* (1902); *The Appearance of our Lord After the Passion* (1907); and *The Last Discourse and Prayer of Our Lord* (1913).

SWEYN I, King of Denmark (d. 1014), son of Harold Bluetooth, the christianizer of Denmark, by his peasant mistress Aesa, according to the Jomsvikinga Saga, though more probably his mother was Queen Gunild, Harold's consort. The lad was a born champion and buccaneer. His first military expedition, in alliance with the celebrated Jomsborg Viking, Palnatoke, was against his own father, who perished during the struggle (*c.* 986). Six years later he conducted a large fleet of warships to England, which did infinite damage, but failed to capture London. During his absence, Denmark was temporarily occupied by the Swedish king, Eric Sersel, on whose death (*c.* 994) Sweyn recovered his patrimony. About the same time he repudiated his first wife Gunild, daughter of duke Mieszko of Poland, and married King Eric's widow, Sigrid. This lady was a fanatical pagan of a disquieting strength of character. Two viceroys, earlier wooers, were burned to death by her orders for their impertinence, and she refused the hand of Olaf Trygvessön, king of Norway, rather than submit to baptism, whereupon the indignant monarch struck her on the mouth with his gauntlet and told her she was a worse pagan than any dog. Shortly afterwards she married Sweyn, and easily persuaded her warlike husband to unite with Olaf, king of Sweden, against Olaf Trygvessön, who fell in the famous seafight off Svolde (1000) on the west coast of Rügen, after a heroic resistance immortalized by the sagas, whereupon the confederates divided his kingdom between them. After his first English expedition Sweyn was content to blackmail England instead of ravaging it, till the ruthless massacre of the Danes on St. Brice's day, Nov. 13, 1002, by Ethelred the Unready (Sweyn's sister was among the victims) brought the Danish king to Exeter (1003). During each of the following eleven years, the Danes, materially assisted by the universal and shameless disloyalty of the Saxon ealdormen, systematically ravaged England, and from 991 to 1014 the wretched land is said to have paid its invaders in ransoms alone £158,000. Sweyn died suddenly at Gainsborough on Feb. 13, 1014.

The data relating to his whole history are scanty and obscure, and his memory has suffered materially from the fact that the chief chroniclers of his deeds and misdeeds were ecclesiastics.

His most remarkable exploit, Svolde, was certainly won at the expense of Christianity, resulting, as it did, in the death of the saintly Olaf. It is not surprising, therefore, that Adam of Bremen, and the monkish annalists who follow him, describe Sweyn as a grim and bloody semi-pagan, perpetually warring against Christian states. But there is another side to the picture. Viking though he was, Sweyn was certainly a Christian viking.

He built churches, he invited English bishops to settle in Denmark (notably Godibald, who did good work in Scania), and on his deathbed he earnestly commended the Christian cause to his son Canute. He was cruel to his enemies but he never forgot a benefit. Thus he rewarded the patriotism of the Danish ladies who sacrificed all their jewels to pay the heavy ransom exacted from him by his captors, the Jomsborg pirates, by enacting a law whereby women were henceforth to inherit landed property in the same way as their male relatives.

Of his valour as a captain and his capacity as an administrator there can be no question. His comrades adored him for his liberality, and the frequent visits of Icelandic skalder to his court testify to a love of poetry on his part. Indeed one of his own strophes has come down to us.

He had a long cleft beard, whence his nickname of *Tiugeskaeg* or Fork-Beard.

See *Danmarks riges historie. Oldtiden og den aeldre middelalder,* pp. 364–381 (1897–1905). (R. N. B.; X.)

SWEYN II or **ESTRITHSON,** King of Denmark (d. 1076), was the son of Estrith, sister of Canute the Great, and of the Earl Ulf. When his father was murdered by Canute, Sweyn fled to Sweden, where he remained until the accession of Magnus the Good to the throne of Norway, at which time Magnus named him earl of Jutland and viceroy of Denmark. Sweyn, however, was not satisfied with this position, aspiring to become king of Denmark. He therefore involved Denmark and Norway in a war which was only terminated in 1047 with Magnus' death, caused by a fall from a horse as he rode in pursuit of the defeated and fleeing Sweyn. His dying wish, however, was that Sweyn be made king of Denmark, and Sweyn thus began the Estrith dynasty, known as the second or middle Danish dynasty, which ruled for nearly 300 years.

Sweyn was almost immediately embroiled in conflict with Harald Haardraade, Magnus' heir to the throne of Norway, who wished also to become king of Denmark. For 17 years, until

1064, the battle between the two countries was pursued sporadically and at the end of that time, although the Norwegians had decisively defeated the Danes in the naval battle of Nissa, the two monarchs declared a truce and the boundaries of Norway and Denmark were declared to be the same as when the war started. After Harald's death in 1066, Sweyn felt free to turn his attention to some other project than the defense of his country. In 1069, therefore, he sent a fleet to assist an internal rebellion against William I of England, a country which he, as nephew of Canute, felt he was entitled to rule. William, however, was able to bribe Sweyn's lieutenant and thus to forestall that threat. In 1075 Sweyn made another similar effort which proved equally abortive.

Sweyn was a devout Roman Catholic, and although he was at one time embroiled with the archbishop of Bremen over Sweyn's marriage to his own stepdaughter, he did much to encourage the development of the church in Denmark. He died in 1076. He left numerous sons, perhaps as many as 14, all illegitimate. Five of them subsequently became kings of Denmark.

SWIDNICA (German SCHWEIDNITZ), a town of Poland in the former Prussian province of Silesia, Ger., on the Weistritz river, 28 mi. S.W. of Breslau by rail. Pop. (1957 est.) 34,000. Swidnica, dating from about the 11th century, received civic rights in 1250. About 1278 it became the capital of a principality, with an area of about 1,000 sq.mi., which belonged to Bohemia from 1353 until 1741, when it passed into the possession of Prussia. The "Pölerei of Schweidnitz" is the name given to the riotous revolt of the town (1520–22) against a royal edict depriving it of the right of coining its own money. The town contains several old churches, one of which was built in the 14th century, and an old town hall. The surrounding country is fertile and highly cultivated, and large quantities of flax and hemp raised encourage the weaving industry. Beetroot for sugar, grain and fruit are also grown. The manufacture of linens, hosiery, furniture, gloves, machinery, margarine, organs, carriages and other hardware goods is carried on. The beer of Swidnica has long been famous.

SWIFT, GUSTAVUS FRANKLIN (1839–1903), U.S. pioneer in the meat-packing industry, was born June 24, 1839, at Sagamore (West Sandwich), Mass. When he was 14 he left school to take a position at a salary of $1 a week working for his brother, a butcher. By 1859, at the age of 20, he had gone into business for himself as a buyer and slaughterer of cattle on a small scale. In that year he opened his own butcher shop in Eastham and soon became the manager of a number of small shops, which he opened himself and placed in charge of other men. In 1872 he became the partner of James A. Hathaway in the firm of Hathaway and Swift. Three years later Swift, who was the cattle buyer for the firm, transferred his headquarters to Chicago, where the centre of the cattle market had shifted. He soon determined that the meat packing business would be substantially more profitable than the meat selling business if some method were devised for shipping fresh meat from Chicago to the east, instead of sending live cattle to be slaughtered on arrival, as was the custom. He therefore hired an engineer to design a refrigerator car which would make this possible, and in 1877 he successfully shipped the first refrigerator carload of fresh meat to the east. In 1878 he formed a partnership with his brother and in 1885, with a capitalization of $300,000, the firm of Swift & Company came into being, with Swift as first president. At his death less than 20 years later, the capitalization had increased to $25,000,000; more than 80 times the original size. In addition to his promotion of refrigerator cars, which was one of the most important factors in the development of the meat packing business, Swift was a leader in the field of turning previously unused parts of slaughtered animals into valuable by-products. He died March 29, 1903, in Chicago.

See Louis F. Swift and Arthur Van Vlissingen Jr., *Yankee of the Yards* (1927).

SWIFT, JONATHAN (1667–1745), dean of St. Patrick's, Dublin, British satirist, was born at No. 7 Hoey's court, Dublin, on Nov. 30, 1667, a few months after the death of his father, Jonathan Swift (1640–1667), who married about 1664 Abigaile Erick, of an old Leicestershire family. His grandfather, Thomas Swift, vicar of Goodrich near Ross, appears to have lost his possessions by taking the losing side in the Civil War and died in 1658 before the restoration could bring him redress. He married Elizabeth, niece of Sir Erasmus Dryden, the poet's grandfather. The young Swift was supported by his uncle Godwin, a Tipperary official; at the age of six he entered Kilkenny school, where Congreve was a fellow student, and he completed his education at Trinity college, Dublin. Here he exhibited few signs of precocious genius, and it was only by special act of indulgence that he obtained his degree; then, on the death of his uncle, he left Ireland and sought counsel of his mother in Leicester.

His first employment commenced towards the close of 1689, when he became secretary to Sir William Temple, who had retired to Moor Park, near Farnham, after the rapid decline of his influence during the critical period of Charles II's reign. It was there that Swift's acquaintance with Esther Johnson, the "Stella" of the famous *Journal,* was begun. Stella's mother was living at Moor Park, as servant of Temple's sister, Lady Giffard. Swift was 22 and Esther 8 years old at the time, and a curious friendship sprang up between them. He taught the little girl how to write and gave her advice in reading. On his arrival at Moor Park, Swift's duties were merely those of account-keeper and amanuensis, but his ability gradually won him the confidence of his employer and he was entrusted with some important missions.

In 1694, however, Swift (who had in the meantime obtained the degree of M.A. *ad eundem* at Oxford) quitted Temple, who had, he considered, delayed too long in obtaining him preferment; but it was only after five months' delay, when Swift had unwillingly begged the favour of a testimonial from his discarded patron, that he was able to obtain the small prebend of Kilroot near Belfast (Jan. 1695).

In the meantime he had grown tired of Irish life and was glad to accept Temple's proposal for his return to Moor Park, where he continued until Temple's death in Jan. 1699. During this period he wrote much and burned most of what he had written. He read and learned even more than he wrote. Moor Park took him away from brooding in Ireland and brought him into the corridor of contemporary history, an intimate acquaintance with which became the chief passion of Swift's life. His *Pindaric Odes,* written at this period or earlier, in the manner of Cowley, indicate the rudiments of a real satirist, but a satirist struggling with a most uncongenial form of expression. Of more importance was his first essay in satiric prose, which arose directly from the position which he occupied as domestic author in the Temple household. Temple had in 1692 published his *Essay upon Ancient and Modern Learning,* transplanting to England a controversy begun in France by Fontenelle. Incidentally Temple had cited the letters of Phalaris as evidence of the superiority of the ancients over the moderns. William Wotton's criticism of Temple's general conclusions caused Swift to write *Battle of the Books* in 1697 in refutation. Boyle's *Vindication* and Bentley's refutation of the authenticity of Phalaris came later. Swift's aim was limited to co-operation in what was then deemed the well-deserved putting down of Bentley by Boyle, with a view to which he represented Bentley and Wotton as the representatives of modern pedantry, transfixed by Boyle in a suit of armour given him by the gods as the representative of the "two noblest of things, sweetness and light." Though written in 1697, the satire remained unpublished until 1704, when it was issued with *The Tale of a Tub.*

After Temple's death, Swift suffered several disappointments in attempting to find employment, but he eventually secured the rectory of Agher in Meath with the united vicarages of Laracor and Rathbeggan, to which was added the prebend of Dunlavin in St. Patrick's—the total value being about £230 a year. He was now often in Dublin, at most 20 mi. distant, and through Lady Berkeley and her daughters—Lord Berkeley was now a lord justice of Ireland—he became the familiar and chartered satirist of the fashionable society there. But he very soon began to grow tired of Ireland again and to pay visits in Leicester and London. His resolution to exchange divinity for politics must appear fully justified by the result. The *Discourse on the Dissen-*

sions in Athens and Rome (Sept. 1701), written to repel the tactics of the Tory commons in their attack on the Partition treaties "without humour and without satire," and intended as a dissuasive from the pending impeachment of Somers, Orford, Halifax and Portland, received the honour of being generally attributed to Somers himself or to Burnet, the latter of whom found a public disavowal necessary In April or May 1704, appeared a more remarkable work. Clearness, cogency, masculine simplicity of diction, are conspicuous in the pamphlet, but true creative power told the *Tale of a Tub*. Although it lacks coherence and attains no conclusion, it is the most strikingly original of Swift's satirical works. In his kindred productions he relies mainly upon a single element of the humorous—logical sequence and unruffled gravity bridling in an otherwise frantic absurdity, and investing it with an air of sense. In the *Tale of a Tub* he lashes out in all directions. The humour, if less cogent and cumulative, is richer and more varied; the invention, too, is more daringly original and more completely out of the reach of ordinary faculties. The book is throughout a mine of suggestiveness. At the same time, it lacks unity and coherence, it attains no conclusion, and the author abuses his digressive method of composition and his convenient fiction of hiatuses in the original manuscript.

In Feb. 1701, Swift took his D.D. degree at Dublin, and before the close of the year he had taken a step destined to exercise a most important influence on his life, by inviting two ladies to Laracor. Esther, daughter of a merchant named Edward Johnson, a dependant, and legatee to a small amount, of Sir William Temple's (born in March 1680), whose acquaintance he had made at Moor Park in 1689, and whom he has immortalized as "Stella," came over with her companion Rebecca Dingley, a poor relative of the Temple family, and was soon permanently domiciled in his neighbourhood. Meanwhile the sphere of his intimacies was rapidly widening. He had been in England for three years together, 1701 to 1704, and counted Pope, Steele and Addison among his friends. In 1708 he wrote the finest example of his irony, the *Argument to prove that the abolishing of Christianity in England may, as things now stand, be attended with some inconveniencies*, and about this time, too (Nov. 1707), he produced his best narrative poem, *Baucis and Philemon*.

The next few months witnessed one of the most amusing hoaxes ever perpetrated against the quackery of astrologers, the victim being a Protestant alarmist and plot vaticinator styled John Partridge. In Jan. 1708, Swift, under the name of Isaac Bickerstaff, issued a solemn prediction that the notorious almanac maker, Partridge, would die at 11 o'clock P.M. on March 29, and on March 30 he published a letter confirming this prophecy. Partridge's fatuous denial and reply to Bickerstaff elicited Swift's amusing *Vindication of Isaac Bickerstaff, Esq.*, in April 1709. The episode has left a permanent trace in literature, for when, in 1709, Steele was to start the *Tatler*, it occurred to him that he could secure the public ear in no surer way than by adopting the name of Bickerstaff.

From Feb. 1708, to April 1709, Swift was in London, urging upon the Godolphin administration the claims of the Irish clergy to the first-fruits and twentieths ("Queen Anne's Bounty"), already granted to their brethren in England. His having been selected for such a commission shows that he was not yet regarded as a deserter from the Whigs, although the ill success of his representations probably helped to make him one. By Nov. 1710, he was again domiciled in London, and writing his *Journal to Stella*, that unique exemplar of a giant's playfulness. In the first pages of this minute record of a busy life we find him depicting the decline of Whig credit and complaining of the cold reception accorded him by Godolphin, whose penetration had doubtless detected the precariousness of his allegiance. Within a few weeks he had become the lampooner of the fallen treasurer, the bosom friend of Oxford and Bolingbroke, and the writer of the *Examiner*, a journal established as the exponent of Tory views (Nov. 1710). He was now a power in the state and the associate of ministers on a footing of perfect cordiality and familiarity. For a brief time he seemed to resume the whole power of the English press in his own pen and to guide public opinion as he would—his services to his party as writer of the *Examiner*, which he quitted in July 1711, were even surpassed by those which he rendered as the author of telling pamphlets. We need not suppose that he was consulted respecting the great Tory strokes of the creation of the twelve new peers and the dismissal of Marlborough (Dec. 1711), but they would hardly have been ventured upon if *The Conduct of the Allies* and the *Examiners* had not come first.

Generous men like Oxford and Bolingbroke cannot have been unwilling to reward so serviceable a friend, especially when their own interest lay in keeping him in England. Swift still had formidable antagonists in the archbishop of York, whom he had scandalized, and the duchess of Somerset, whom he had satirized. Anne was particularly amenable to the influence of priestly and female favourites, and it must be considered a proof of the strong interest made for Swift that she was eventually persuaded to appoint him to the deanery of St. Patrick's, Dublin. In June 1713 he set out to take possession of his dignity, and encountered a very cold reception from the Dublin public. The dissensions between the chiefs of his party speedily recalled him to England. He found affairs in a desperate condition. The queen's demise was evidently at hand and public opinion was turning towards the Whigs when the Tories manifestly could not be trusted to maintain the Protestant succession. Bolingbroke's brain teemed with the wildest plans. Swift's mediation was unavailing.

When the discord of Oxford and Bolingbroke had become patent to all the nation, Swift, foreseeing, as is probable, the impending fall of the former, retired to Upper Letcombe, in Berkshire, and there spent some weeks in the strictest seclusion. This leisure was occupied in the composition of his remarkable pamphlet, *Some Free Thoughts on the Present State of Affairs*, which indicates his complete conversion to the bold policy of Bolingbroke. The utter exclusion of Whigs as well as Dissenters from office, the remodelling of the army, the imposition of the most rigid restraints on the heir to the throne—such were the measures which, by recommending, Swift tacitly admitted to be necessary to the triumph of his party.

Bolingbroke's daring spirit, however, recoiled from no extreme, and, fortunately for Swift, he added so much of his own to the latter's ms. that the production was first delayed and then, upon the news of Anne's death, immediately suppressed. This incident only just anticipated the revolution which, after Bolingbroke had enjoyed a three days' triumph over Oxford, drove him into exile and prostrated his party. Almost the first acts of Bolingbroke's ephemeral premiership were to order him £1,000 from the exchequer and despatch him the most flattering invitations. The same post brought a letter from Oxford, soliciting Swift's company in his retirement; and, to the latter's immortal honour, he hesitated not an instant in preferring the solace of his friend to the offers of Bolingbroke. When, a few days later, Oxford was in prison and in danger of his life, Swift begged to share his captivity; and it was only on the offer being declined that he finally directed his steps towards Ireland, where he was very ill received. The draft on the exchequer was intercepted by the queen's death.

During these four busy years of London life, Swift had entered deeply into the literary life of the period. He was treasurer and a leading member of the Brothers, a society of wits and statesmen which recalls the days of Horace and Maecenas. He promoted the subscription for Pope's *Homer*, contributed some numbers to the *Tatler*, *Spectator*, and *Intelligencer*, and joined with Pope and Arbuthnot in establishing the Scriblerus Club, contributing to *Martinus Scriblerus*, his share in which can have been but small, as well as *John Bull*, where the chapter recommending the education of all blue-eyed children in depravity for the public good must surely be his. His miscellanies, such as *A Meditation upon a Broomstick*, and the poems *Sid Hamet's Rod*, *The City Shower*, *The Windsor Prophecy*, *The Prediction of Merlin*, and *The History of Vanbrugh's House*, belong to this period. A more laboured work, his *Proposal for Correcting, Improving and Ascertaining the English Tongue* (1712), in a letter to Harley, suggesting the regulation of the English language by an academy, is chiefly remarkable as a proof of the deference paid to French taste. His

History of the Four Last Years of the Reign of Queen Anne is not on a level with his other political writings.

To Swift the change from London to Dublin meant for the time the fall from unique authority to absolute insignificance. All share in the administration of even Irish affairs was denied him; every politician shunned him; and his society hardly included a single author or wit. Before and after his elevation to the deanery of St. Patrick's, Esther Johnson and Mrs. Dingley continued to reside near him, and superintended his household during his absence in London. He had offered no obstacle in 1704 to a match proposed for Stella to Dr. William Tisdall of Dublin. Whatever the cause, his conduct proved the fatal embitterment of his life and Stella's and yet another's. He had always been unlucky in his relations with women. Esther Vanhomrigh, "Vanessa" (b. Feb. 14, 1690), the daughter of a Dublin merchant of Dutch origin, had become known to Swift at the height of his political influence. He lodged close to her mother, and Vanessa insensibly became his pupil, while he became the object of her impassioned affection.

But Swift was devoid of passion. Of friendship, even of tender regard, he was fully capable, but not of love, and Vanessa's ardent and unreasoning display of passion was beyond his comprehension. Yet Vanessa assailed him on a very weak side. The strongest of all his instincts was the thirst for imperious domination. Vanessa hugged the fetters to which Stella merely submitted. Flattered to excess by her surrender, yet conscious of his binding obligations and his real preference for Stella, he could neither discard the one beauty nor desert the other. When Vanessa's mother died (1714), she followed him to Ireland, taking up her abode at Celbridge within ten miles of Dublin Unable to marry Stella without destroying Vanessa, or openly to welcome Vanessa without destroying Stella, he was thus involved in the most miserable embarrassment; he continued to temporize. Had the solution of marriage been open Stella would undoubtedly have been Swift's choice, but some mysterious obstacle intervened.

Meanwhile Swift's efforts were directed to soothe Miss Vanhomrigh, to whom he addressed *Cadenus* [*Decanus*] *and Vanessa,* the history of their attachment and the best example of his serious poetry, and for whom he sought to provide honourably in marriage, without succeeding either in his immediate aim or in thereby opening her eyes to the hopelessness of her passion. Worn out with his evasions, she at last (1723) took the desperate step of writing to Stella or, according to another account, to Swift himself, demanding to know the nature of the connection with him, and this terminated the melancholy history as with a clap of thunder. Stella sent her rival's letter to Swift, and retired to a friend's house. Swift rode down to Marley Abbey with a terrible countenance, petrified Vanessa by his frown, and departed without a word, flinging down a packet which only contained her own letter to Stella. Vanessa died within a few weeks. She left the correspondence for publication, but it was suppressed until it was published by Sir Walter Scott. Five years after Vanessa's death Stella died, on Jan. 28, 1728.

Between the death of Vanessa and the death of Stella came the greatest political and the greatest literary triumph of Swift's life. Although he was not an Irish patriot in the strict sense of the word, his pride and sense of equity alike revolted against the stay-at-home Englishmen's contemptuous treatment of their own garrison, and he delighted in finding a point in which the triumphant faction was still vulnerable. His *Proposal for the Universal Use of Irish Manufactures,* published anonymously in 1720, urging the Irish to disuse English goods, became the subject of a prosecution, which at length had to be dropped. A greater opportunity was at hand. A patent for supplying Ireland with a coinage of copper halfpence was accorded to William Wood on such terms that the profit accruing from the difference between the intrinsic and the nominal value of the coins, about 40%, was mainly divided between him and George I.'s favourite duchess of Kendal, by whose influence Wood had obtained the privilege. Swift now had his opportunity, and the famous six letters signed M. B. Drapier (April to Dec. 1724) soon set Ireland in a flame. Every effort was used to discover, or rather to obtain legal evidence against, the author, but none could be procured; the public passion swept everything before it; the patent was cancelled.

The noise of the *Drapier Letters* was followed by the anonymous publication of *Travels Into Several Remote Nations of the World,* in four parts, by Lemuel Gulliver, first a surgeon and then a captain of several ships (Benjamin Motto, Oct. 1726), the work being well advanced, it would seem, by 1720. The keenness of the satire on courts, parties and statesmen certainly suggests that it was planned while Swift's disappointments as a public man were still rankling and recent. Although he was afraid of the reception the book would meet with, especially in political circles, the world chose to be diverted by it. In the first two parts the misanthropy is quite overpowered by the fun. The third part, equally masterly in composition, is less felicitous in invention; and in the fourth Swift has indeed carried out his design of vexing the world at his own cost.

Swift's grave humour and power of enforcing momentous truth by ludicrous exaggeration were next displayed in his *Modest Proposal for Preventing the Children of Poor People from being a Burden to their Parents or the Country,* by fattening and eating them (1729). The *Directions to Servants,* a satire on domestics, was first published in 1745, while *Polite Conversation,* written in 1731 was published in 1738. Little beyond occasional verses—trivial and often indecent—followed, but the delightful *Hamilton's Bawn,* and the verses on his own death (1731) are exceptions, and in *The Legion Club* of 1736 he composed the fiercest of all his verse satires. His popularity remained as great as ever (he received the freedom of Dublin in 1729), and he governed his cathedral with great strictness and conscientiousness; but the attacks of giddiness to which he had always been subject increased upon him, and he grew more and more capricious and morbidly suspicious. In March 1742 it was necessary to appoint guardians of Swift's person and estate. In September of the same year his physical malady reached a crisis, from which he emerged a helpless wreck, with faculties paralysed rather than destroyed, and he eventually sank into the dementia which preceded his death on Oct. 19, 1745. He was interred in his cathedral at midnight in a coffin by the side of Stella's. His epitaph was written by himself.

An object of pity as well as of awe, Swift is one of the most tragic figures of English literature. His master passion was imperious pride—lust for despotic dominion; place, profit and literary fame were comparatively indifferent to him. Contemptuous of the opinion of his fellows, he hid his virtues, paraded his faults, affected some failings from which he was really exempt, and, since his munificent charity could not be concealed from the recipients, laboured to spoil it by gratuitous surliness. "To think of him," says Thackeray, "is like thinking of the ruin of a great empire." Among those influenced by Swift may be mentioned Chesterfield, Smollett, Cobbett, Hazlitt, Scott, Borrow, Newman, Belloc.

BIBLIOGRAPHY.—The contemporary lives of Swift, most of which contain a certain amount of apocrypha, are those of Lord Orrery (1751); Patrick Delany's *Observations on Orrery* (1754); Deane Swift's *Essay Upon the Life of Swift* (1755); and Thomas Sheridan's *Life* (1785). John Hawkesworth, in the life prefixed to his edition of the *Works* in 1755, adds little of importance. Samuel Johnson's *Life* in "Lives of the Poets," vol. 3 (1781), is marred by manifest prejudice. J. Barrett produced an *Essay Upon the Early Life* of some value (1808). Six years later came the useful biography of Sir Walter Scott and, in 1819, appeared the elaborate *Life* by W. Monck Mason in the form of an appendix to his ponderous *History of St. Patrick's.*

A new epoch of investigation was inaugurated by John Forster, who began a new scrutiny of the accumulated material and published his first volume in 1875. Invaluable in many respects, it exhibited the process as well as the result of biography, and never got beyond 1711. The *Life* by Sir Henry Craik (1882 and reissues) continued to hold the field.

Valuable monographs were produced by Sir Leslie Stephen (Men of Letters and the Memoirs, in the *Dictionary of National Biography*), by Thackeray in his *English Humourists,* by W. R. Wilde in his *Closing Years of Dean Swift's Life,* by Lecky in his *Leaders of Public Opinion,* by G. P. Moriarty, J. Churton Collins (1893), Max Simon (1893), Henriette Cordelet (1907) and Sophie Shilleto Smith (1910). The anecdotes of Swift related in Spence's *Laetitia Pilkington,* Wilson's *Swiftiana,* Delany's *Autobiography,* etc., though often amusing, can hardly be accepted as authentic.

Later biographical and critical works include Carl Van Doren, *Swift* (1930; 1931); S. L. Gwynn, *The Life and Friendships of Dean Swift* (1933); W. D. Taylor, *Jonathan Swift* (1933); Ricardo Quintana, *Mind and Art of Jonathan Swift* (1936; reprinted, 1953), *Swift: an Introduction* (1955); Bertram Newman, *Jonathan Swift* (1937); Bernard Acworth, *Swift* (1948).

The collective editions of Hawkesworth (various issues, 1755–79), T. Sheridan (1785), John Nichols (1801, 1804, 1808), Scott (1814, 1821) and Roscoe (2 vol., 1849) were in most respects superseded by the edition in Bohn's Standard Library in 14 vol. (including the two subsequently issued volumes of *Poems;* 1897–1910) arranged as follows: i, biographical introduction by W. E. H. Lecky, *Tale of a Tub, Battle of the Books, Critical Essay Upon the Faculties of the Mind, The Bickerstaff Pamphlets,* etc., ed. by Temple Scott; ii, *Journal to Stella,* ed. by F. Ryland (two portraits of Stella); iii and iv, *Writings on Religion and the Church,* ed. by Temple Scott; v, *Historical and Political Tracts—English,* ed. by Temple Scott; vi, *Historical and Political Tracts—Irish,* ed. by Temple Scott; vii, *The Drapier's Letters,* ed. by Temple Scott; viii and xi, literary essays, including *Gulliver's Travels,* ed. by G. R. Dennis, *A Proposal for Correcting, Improving and Ascertaining the English Tongue, Hints Towards an Essay on Conversation, Character, Directions to Servants* and *Autobiographical Fragment,* ed. by Temple Scott; ix, contributions to the *Examiner, Tatler, Spectator,* etc., ed. by Temple Scott; x, historical writings, including the *Four Last Years, Abstract of English History* and *Remarks on Burnet,* ed. by Temple Scott; xii, essays on the portraits, etc., bibliography by W. Spencer Jackson and index; twelve portraits of Swift are included in the work, in addition to two portraits of Stella and one of Vanessa; xiii and xiv, poems, ed. by W. Ernst Browning.

Translations and editions of *Gulliver's Travels* have been numerous; it was included in vol. 36 of "Great Books of the Western World" (1952), ed. by Robert M. Hutchins. "Valuable Notes for a Bibliography of Swift" were published by S. Lane Poole in *The Bibliographer* (Nov. 1884). *See* also H. Teerink (ed.), *Bibliography of the Writings in Prose and Verse of Jonathan Swift* (The Hague, 1937).

(R. G.; X.)

SWIFT, a bird so called from the speed of its flight. Despite its appearance, the swift (*Apus apus*) is in no way related to the swallow and is not even a passerine bird, its affinities being with the hummingbirds. The common swift is a summer visitor to Europe, arriving in May and returning to Africa at the end of August. It nests in holes in buildings, less frequently in cliffs and quarries. On the wing it gives the idea of a bow and arrow; it is a larger bird than the swallow and its flight is swifter and steadier. Except for a grayish-white patch under the chin, the plumage is entirely sooty black. Near sunset the birds often sweep round in screaming bands, and sometimes then ascend out of sight. It has been stated that they may spend the night on the wing at great heights; further observation on this point is needed, as also on the assertion that swifts actually pair in mid-air. A larger species, *A. melba,* with white under parts, inhabits the mountains and cliffs of southern Europe and is very numerous in the old water tower at Lucerne.

The allied genus *Collocalia* constructs nests of saliva and these are used by the Chinese for soup. The birds breed in caves, and range from north Madagascar to the Marquesas, one species occurring in the hill country of India. The chimney swallow of the United States (*Chaetura pelagica*) is also a swift, cementing its nest with saliva. It is migratory.

SWIMMING, the action of self-support and self-propulsion on or in the water; though used by analogy of inanimate objects, the term is generally connected with animal progression and especially with the art of self-propulsion in the water as practised by man. It is one of the most useful of man's physical accomplishments. There have been many cases in which beginners have demonstrated some ability in swimming upon their first immersion in the water, but generally speaking it is a skill that must be acquired.

Types of swimming strokes commonly used are the breast, side, crawl and back strokes. Each of these has been popular at different periods. The Australian crawl, comparatively recently popularized, is probably the best known stroke. With the increased acceptance of swimming as a recreation came its organization as a national and international competitive sport. Swimming was one of the sports included in the revived Olympic games at Athens in 1896, and it continues to hold an important place in the Olympics.

This article is divided into the following sections:

1. History
2. Teaching Swimming
3. Swimming Strokes
4. Competitive Swimming
5. Floating
6. Diving
7. Channel Swimming
8. Open-Water Swimming

1. History.—Swimming was rated highly in the days of Greece and Rome, practised widely and stressed in the training of warriors. But it fell into almost complete disuse throughout Europe in the middle ages, when the belief became general that outdoor bathing helped to spread the epidemics that so often swept the continent. It was not until the second half of the 19th century that the prejudice was overcome sufficiently for aquatic activities to be resumed. Competition was resumed, first in Great Britain, then elsewhere, and the study of swimming technique led to gradual improvement in methods.

As knowledge grew, there came steadily increasing appreciation of the value of swimming in protecting life as well as in physical education, for it had gained recognition as the most beneficial of all forms of exercise. Physical educators agreed that there is no physical activity that can contribute as much as swimming to a person's physical well-being.

Teaching of swimming was taken up by the schools; sectional and national learn-to-swim campaigns were fostered in most countries. During World War II nearly all belligerent nations included swimming as a part of the training of servicemen, and after the war the gains in swimming instruction and promotion that had been made were consolidated and furthered by national organizations such as the U.S. Conference for National Cooperation in Aquatics. This organization, operating informally and meeting annually, sought to further the cause of swimming specifically because of its safety value but also because of its value as an all-around exercise.

2. Teaching Swimming.—Many methods of swimming instruction were tested as changes in stroke took place, but in the long run the great majority of teachers enrolled in one of two predominant schools, the European, whose protagonists believe the breast stroke should be taught first, and the U.S., whose followers assert that the crawl is mastered far more readily than any other stroke. Both schools favour preliminary drills on land or in shallow water, so that beginners may gain some knowledge of the required movements before attempting to swim.

The greatest handicaps in learning are failure to relax and haste in performing the action. Fear of the water, or the mere nervousness experienced by most nonswimmers, generally causes muscle tension and engenders the feeling that it is necessary to thrash wildly with arms and legs in order to keep afloat. Every effort must be made to overcome these natural tendencies, for rapid progress is dependent upon complete relaxation and unhurried movements. Instructors usually help pupils to become accustomed to immersion by having them play in shallow water, ducking the head and trying to pick up objects from the bottom, before starting schooling.

During World Wars I and II, when great numbers of men in their late 20s and early 30s had to be taught and speed in training was essential, a method of starting the pupil on his back was developed. In this position floating was facilitated, developing confidence in the water; normal breathing was utilized in contrast with the breathing difficulty in face-down strokes, and a very simple propulsive action was taught—a frog kick with a synchronous short arm stroke, the arms being underwater to prevent splash, moving from side, horizontal, downward to the thighs.

3. Swimming Strokes.—In the early stages of swimming competition, the standard racing style was the side stroke, in which both arms remain submerged throughout, while the legs execute a wide scissor kick, opening and closing in movements resembling those of walking. The first advance over this was made when swimmers conceived the idea of minimizing resistance by thrusting the upper arm forward above the surface, instead of underwater. The new stroke was called the single overarm. The double overarm followed, with both arms recovering above the surface. This stroke was made prominent in 1893 by an Englishman, J. Trudgen, who told of picking it up in South America. It took his name, misspelled Trudgeon in some countries, and served later to introduce the basic arm action of the crawl, the most efficient mode of swimming developed so far.

The changes in leg drive were marked by a consistent trend to-

ward narrower and faster movements. Following the advent of the trudgen, the wide scissor kick of the side stroke, originally performed with legs bent excessively, was reduced in scope and executed with the legs a good deal straighter. Then, with the introduction of the crawl, the legs began to whip up and down alternately in a gradually quickening and diminishing thrash, speeding up by degrees from two to ten proportionately smaller

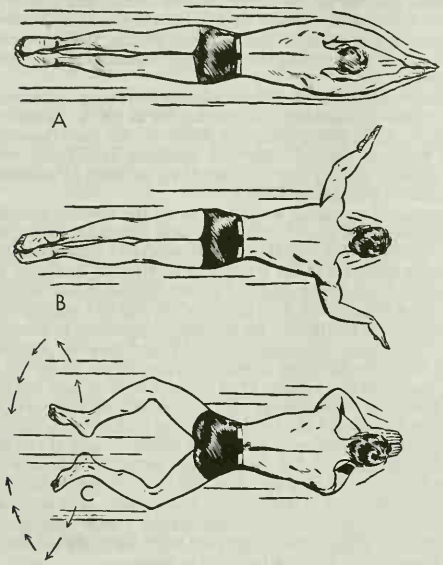

FIG. 1.—THE BREAST STROKE

A. Position at start and finish of stroke. B. Drive of arms, swimmer inhaling. C. Start of recovery of arms; legs ready for kick; swimmer exhaling under water. Arrows indicate continuation of leg drive

scissors to each cycle of the two arms.

Breast Stroke.—Two styles of breast stroke have been evolved, the ancient and orthodox variety, believed to be the oldest of all strokes, and the butterfly, a racing adaptation brought out in 1935 by Henry Myers of the United States. The orthodox breast stroke, used for teaching beginners, is a stroke of great practical value. It affords the means to assist a tired swimmer or support a drowning person with comparatively little effort; it enables the swimmer to advance safely, head up, through waters littered with flotsam or wreckage; it is the only stroke that makes it possible for soldiers to swim under the burden of heavy packs and arms. It also has the advantage, during war, of being noiseless, as the arms and legs are underwater in recovery and propulsion. The butterfly is a competitive style only.

The two styles are distinguished by differences in the action of the arms. In both the arms start their drive from full extension in front, hands close together on the surface, palms down. But in the orthodox breast stroke the arms propel by pressing down and outward at a slant that places them at an angle of about 80° on reaching the shoulder line, when the elbows are brought to the sides, the hands to the chest, again palms down, and the arms shot forward underwater to their original position. In the butterfly the arms pull under the body all the way to the thighs, then emerge and fling forward above surface in circular motion. The leg action of both strokes, known as the frog kick, is performed by drawing up the legs in a manner somewhat like that of squatting, knees apart, feet close and pointed; then the feet are turned outward, and, with a continuous sweep, the legs are kicked vigorously back and out to an angle of about 90° and snapped sharply together.

The closing movement occurs as the arms shoot forward in recovery. After the kick the body is allowed to glide motionless for a brief spell, forming a straight line from hands to pointed toes. The orthodox stroke may be used comfortably head up, but greater speed is attained in both styles by raising the head to inhale during the drive of the arms and dipping the face to exhale underwater during their recovery. The butterfly is the faster by a wide margin.

The butterfly was revised by the Fédération Internationale de Natation Amateur (Helsinki congress, 1952) to permit a synchronous up-and-down action of the legs characterized by the term "fishtail kick," or "dolphin," which further increases the speed of this type of breast stroke.

Side Stroke.—The side stroke is valued chiefly for lifesaving purposes, as it is used in the most efficient carries devised for the rescue of the drowning. But it is liked for open-water pleasure swimming also, because it is faster than the breast stroke and the face remains constantly above water. The body stays steadily on its side, as the name implies, and the arms propel alternately. The underarm starts from comfortable extension overhead and pulls below the body to the waist, then bends upward and pushes forward; the upper arm drives a little outside the body line, sweeping to the thigh, and recovers close to the surface. The legs open slowly for the scissor kick, the under leg moving backward, the upper leg forward, both knees bent a little, feet pointed; when at an angle of about 50° they whip smartly together, the closing movement timed with the finish of the upper arm drive. This stroke is also excellent for survival swimming or for emergency situations where it is imperative that the arms in all actions be kept underwater.

Crawl Stroke.—The crawl is the fastest of all known strokes, yet it requires little effort, as attested by the fact that many of the greatest feats of endurance achieved by men and women stand to its credit, including the crossing of the English channel and swimming the length of the Panama canal. Its remarkable speed has made it not only supreme in the competitive field but also extremely valuable in saving drowning persons, getting away from a sinking ship and battling strong tides or currents in the effort to reach safety.

There is evidence that the crawl was well known in some of the South sea islands long before Richard Cavill of Australia introduced it about 1900 and broadcast its merits by breaking the world record for 100 yd. with it. It was discovered that the stroke had been popular in the Solomons as far back as the oldest islanders could remember, and long before it was introduced in Australia sportsmen in Honolulu frequently arranged swimming races for young Hawaiian swimmers at Waikiki beach in which the boys used a stroke very similar to the one later demonstrated with

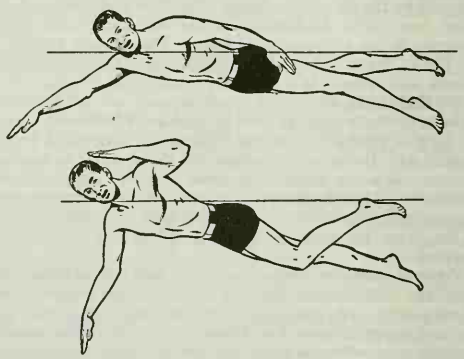

FIG. 2.—THE CRAWL STROKE, INTRODUCED INTERNATIONALLY IN 1908

such success by Duke Kahanamoku. The name of crawl was coined as the result of a press account of the initial showing of the stroke, in which the writer stated that Cavill appeared literally to crawl over the water. Cavill performed two kicks per full stroke,

and his action was adopted universally in Australia, so the leg drive remained unchanged until the stroke made its way to the United States.

The earliest knowledge of the crawl obtained in the U.S. was derived from hazy newspaper accounts and descriptions of Cavill's strokes. In attempting to imitate the action, U.S. swimmers unwittingly developed a faster leg drive, executing four scissoring kicks per stroke instead of the two performed by Cavill. The new leg drive was combined with the double overarm action of the trudgen, and the resulting stroke was called the four-beat crawl, to distinguish it from the two-beat variety.

Meanwhile, experiments had led to the belief that the four-beat leg thrash was most effective when composed of one comparatively wide and three very narrow scissoring motions. This style, termed the four-beat trudgen crawl or the four-beat single rhythm crawl, became the accepted racing stroke. The combination of movements was responsible for so notable an improvement in average performances that technical experts conceived the possibility of obtaining still greater speed from a six-beat drive set to a double rhythm—two major and four minor kicks—which would minimize resistance and afford more even distribution of propelling power. But coaches were unanimous in declaring that the swift thrash would prove entirely too laborious for distances longer than 100 yd., and the subject was dropped temporarily.

Late in 1917 two young swimmers of the New York Women's Swimming association, Charlotte Boyle and Claire Galligan, determined to give the six-beat a trial, and by the summer of 1918 they broke records with it over the longer regulation courses, 880 yd. and one mile. So convincing was this demonstration that it caused a sudden change of mind among the coaches and competitors. The six-beat crawl immediately won favour in the U.S., presently in other countries, and within a few years it had become the recognized stroke the world over, not only for racing but also for all-around purposes. Another Women's Swimming association member, Ethel McGary, successfully developed in turn the eight- and ten-beat varieties of the crawl, but as the eight- and ten-beat strokes were found to require exceptionally limber legs in time the six-beat crawl came to be accepted as the standard action. Nevertheless, a great many women and some men used the eight-beat successfully. It enabled Gertrude Ederle of the U.S. to cross the English channel in 14 hr. 34 min. and break the men's record for the course, 16 hr. 33 min. No men and very few women have made their mark with the ten-beat crawl.

The extent of the progress made in the U.S. through the adoption and development of the crawl is best illustrated by the lowering of the U.S. records in regulation competitive events—the 100 yd., 220 yd., 440 yd. in 25-yd. pools; and 880 yd. and 1 mi. over long courses (50 yd. and upward). By 1956 the men's record in the 100 yd. had dropped from 58.6 to 48.9 sec.; in the 220 yd. from 2 min. 25.4 sec. to 2 min. 3.4 sec.; in the 440 yd. from 5 min. 22.2 sec. to 4 min. 26.7 sec.; in the 880 yd. from 11 min. 24.2 sec. to 9 min. 30.7 sec.; and in the mile from 25 min. 24.4 sec. to 19 min. 40.4 sec.

The answer to what will be the ultimate in speed swimming, a question asked often because of the frequency of record breaking, seems to be that the development of speed swimming is still in its infancy, as witnessed by the advances made in skill since the introduction of the crawl stroke. With increased skill in swimming as a result of widespread and ever-expanding instruction and facilities, it is difficult even to guess what the future holds.

The correct position for swimming the crawl is like that assumed in standing erect on tiptoe. The arms move alternately, so timed that one will start pulling just before the other has completed its drive, thereby making the propulsion continuous. Each arm catches in front of the body in line with the shoulder on the same side, almost fully extended with elbow and shoulder slightly flexed. Such slight flexion affords greater strength and arm position than does full extension. The elbow on catch should be slightly higher than the hand, forearm turned slightly inward, wrist straight, hand palm down, fingers and thumb close but not cupped. The power of the arm stroke can be thought of as pressing downward and backward during the first third of the stroke, pulling during the middle third and pushing through and backward but not upward during the final third of the action, completing an arc of roughly 180°. The direction of pull should be on a line from the shoulder moving slightly under the body and out past the thigh on recovery.

On recovery the elbow is bent, the elbow quickly flexes and the forearm circles quickly out and around until it points toward the place of entry. Then the elbow is extended for the catch of the arm on a line with the shoulder.

The legs are held fairly straight but fully relaxed. The legs whip up and down alternately in an undulating action so that in both the up kick and down kick there will be a backward push against the water with the lower leg and more so with the foot. The scope of the thrash must vary somewhat according to the individual length of leg, the number of beats used per stroke and the distance to be covered.

Breathing is effected by turning the head to either side during the recovery of the upper arm, for the purpose of a gasping inhalation, and then dropping the head squarely face downward, exhaling through the nose or nose and mouth. One breath is taken for every full stroke (right and left arm). The skilled swimmer learns to breathe on either side, but the regular breathing pattern is established on one side or the other.

Crawl balance is attained by working the arms independently of the shoulders so that the body lies perfectly flat even during the action of inhalation, when the head turns without distorting the trunk position. The shoulders are level at all times; the water line of the head is at the eyebrows when the face is down, and any distortion of the trunk in the shoulder or pelvic girdle should be avoided.

Backstroke.—The style of the backstroke in vogue prior to 1912 was aptly described as an inverted breast stroke. But that year Harry Hebner, the U.S. champion, amazed spectators in the Olympic race at Stockholm with his supine crawl, never before seen in Europe, winning in record time. That exhibition soon drove the old stroke (double overarm on the back with a frog kick) into discard, for the back crawl is a good deal faster, requires less effort and is easier to learn. In the back crawl the swimmer's position is such that the body is in a horizontal plane, head lifted slightly upward looking at the feet, with hips slightly lower than the shoulders. The arms work alternately and are intertimed as in the prone crawl or free style. Each arm stretches above the head and enters the water six inches to a foot outside the shoulder line, pulling and driving to the thigh with a circular outward motion at a depth sufficient only to keep the arm underwater in a plane

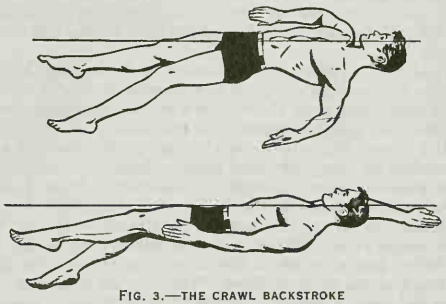

FIG. 3.—THE CRAWL BACKSTROKE

parallel to the surface of the water. The arms in recovery are carried straight or with a partially flexed elbow to the catch, either in line with the shoulder or in a semicircular motion sideward and upward. The shoulders and trunk are kept flat without any rolling. The legs execute an alternate thrash as in the prone crawl; the knees bend more but are kept underwater at all times. This makes for a much deeper leg kick (leg and foot) than in the prone crawl. In the back crawl, with the face out of water all the time, the breathing presents no difficulties as it does in the breast stroke and prone crawl.

The back crawl appeared on the scene last of all of the competitive styles and has undoubtedly made the greatest strides in record breaking.

4. Competitive Swimming.—Swimming joined the ranks of standardized competitive athletics in 1869, when the Amateur Swimming association was founded in England. Other countries followed the lead at intervals, the U.S. launching the Amateur Athletic union in 1878, and before many more years nearly all western nations had formed governing bodies and taken measures to promote the sport. Eventually, national championships for men and women, as well as intervarsity and interscholastic title tests, were instituted everywhere. International competition was inaugurated with the holding of the revived Olympic games at Athens in 1896 when four swimming events were placed on the program. Activities grew apace thereafter, and frequent intercountry encounters were added to the quadrennial Olympiads, making increasingly evident the desirability of unifying rules and regulations.

To this end, the Fédération Internationale de Natation Amateur, composed of controlling national organizations, was formed in London in 1908. It undertook to draft a code, supervise and register world's records and outline programs for Olympic games. As membership was made conditional to the observance of all F.I.N.A. rules, universal standards were soon established. The federation chose swimming, diving and water polo as the branches of aquatic sports over which it would assume authority. The three classes of swimming events already popular were retained: free style, permitting the use of any kind of stroke; backstroke, regulated by the one provision that the entire course must be covered in supine position; and breast stroke, confined to this mode of swimming and governed by strict rules concerning the execution of the action.

Free-style races have always furnished the bulk of the competition in the Olympic schedule. In national championships, free-style predominance is even greater. Although long-distance races are an integral part of summer activities, most competition takes place in pools. The building of enclosed and heated pools speeded the growth of aquatic contest during the winter months.

In the 1896 Olympics, Hungary took top honours with two wins to one each for Greece and Austria. The II Olympiad in 1900 saw Australia, Germany and Great Britain win two events each and France one. The United States took its first Olympic swimming victories at St. Louis in 1904, winning two of the free-style events and a relay. Germany, with four victories, however, captured top honours. Great Britain, in 1908, showed its superiority by winning four of the six swimming events, but the 1912 Olympics, marked by the initial appearance of women contenders, was practically a standoff with Canada, Germany and the U.S. winning two events each.

World War I caused the 1916 games to be canceled, but by 1920 the U.S. was ready to profit from earnest study of the crawl. In the 1920 Olympics the U.S. took five of seven swimming events, the other two going to Sweden. At Los Angeles in 1932, while the U.S. women successfully defended their laurels, the men were defeated by the vastly improved Japanese, winners of all but one of the contested swims. Competition was close at Berlin in 1936 in the men's swimming events, which resulted in three victories for Japan, two for the U.S. and one for Hungary. The Netherlands' women's team won four of the five women's races—the 100- and 400-m. free style, the backstroke and the relay—losing only the breast-stroke event to Japan. This was the first time that Japan had taken a first place in the Olympic games in women's swimming and the first time since World War I that the U.S. women's team had been unable to win a first place.

In the London Olympic games of 1948 the U.S. men's team won first place in all six events, the first time since the Olympic games revival that any nation had achieved such a sweep in the Olympics. In women's swimming, the team from Denmark, which had been sharing honours with the Dutch team in international swimming circles since 1936, won two first places—the 100-m. free style and the backstroke. The team from the Netherlands won the breast-stroke event; and the U.S. team with Ann Curtis won the 400-m. free-style race and the relay.

The U.S. maintained its leading position in men's swimming at the Helsinki Olympic games, 1952, winning four races—the 100- and 1,500-m. free style, the backstroke and the relay. France, after great advances during several Olympiads, won a magnificent victory in the 400-m. free style, and Australia won the breast stroke. Women's swimming supremacy saw another great shift, from northern Europe, the Netherlands and Denmark to central Europe. The women's team representing Hungary won four of the five races in a most outstanding and convincing manner—the 100- and 400-m. free style, the breast stroke and the relay—and the backstroke race was won by South Africa, the first time this team had ever won an Olympic swimming competition.

The 1956 Olympic games at Melbourne, Austr., served notice that the Australians had arrived as the world power in swimming. Australian competitors took all free-style titles in both men's and women's events in a magnificent display of form and power. New records were established for every event on the Olympic program except for the men's and the women's 200-m. breast stroke events.

Two years later, in Australian state and national competition in the spring of 1958, 31 new world records were reported. Fifteen-year-old Latvian-born John Konrads and his 13-year-old sister Ilsa accounted for 16 of the new marks.

At Rome, for the 1960 Olympics, Australia and the U.S. took four events each in the men's swimming events while in the women's competition five of the seven races went to the U.S. swimmers and one each to Australia and Great Britain.

With increased swimming facilities the world over, and means of communication and transportation making possible more and more international meeting in addition to the Olympic games, excellence in performance follows no one pattern or nation, which a checking of the record books clearly indicates.

A summary of first places in aquatic events (swimming, diving and water polo) in the Olympic games indicates the broad spread of the sport since the first of the modern games in 1896. In the men's events the order through 1960 was: U.S. 56, Australia 15, Germany 12, Japan 10, Great Britain 10, Hungary 9, Sweden 6, France 3, Canada 2, Italy 2, Argentina, Austria, Greece and Mexico 1 each. First place results for women were: U.S. 37, Australia 6, Netherlands 6, Germany 4, Great Britain 4, Hungary 4, Denmark 3, Sweden 2, Japan 1 and South Africa 1.

5. Floating.—One of the most useful accomplishments of a swimmer is floating. It is a matter of buoyancy, which varies with individuals. Buoyancy cannot be taught, but body balance in the water can be acquired through knowledge. In learning to float, the beginner experiences difficulty in keeping the legs in the horizontal plane, and this can be remedied by the counterbalance of extending the arms beyond the head, whether in face down or back floating position.

Floating motionless can be performed with proper breath control and body balance. Bending the knees to shorten the axis often improves balance in the water. Supine or back floating with a minimum of motion of the arms and legs is a valuable safety skill for the swimmer as well as for the novice. Wartime research by naval authorities showed that this type of floating conserves energy and, in areas where detonations may occur, minimizes percussion danger, facilitating survival with fewer internal injuries.

Movement of the legs in an alternating walking motion and downward pressure of the hands and forearms is the only motion required to keep the body comfortably afloat in the back floating position.

6. Diving.—The method of entering the water with either head foremost or feet foremost is called diving. Shortly after man learned to swim, the dive became closely related to swimming, perhaps only as a quick way of getting into the water in escaping from wild animals or fire. Diving for pleasure and exercise, as it is done today, can most easily be performed by standing on the edge of a pool or dock, holding the arms overhead and bending forward at the hips until the balance is lost. The entry into the water will be smooth and without ill effect.

Diving, plain and fancy, which is today a part of all aquatic contests, developed rapidly through the first half of the 20th

century. Many gymnastic and tumbling stunts can be performed before entry is made into the water, and the thrill of this combination is a challenge to young persons to achieve perfection in this stimulating sport.

Diving became a part of the swimming program of the Olympic games as early as 1904. The program at that time was plain high diving and variety high diving, with contestants performing from both the 5-m. and 10-m. firm platforms. The contest was composed of compulsory dives and voluntary dives. Springboard diving, plain and variety, was performed from an elastic board at heights of 1 m. and 3 m. above the water. It was necessary to have judges to mark the dives performed, with attention paid to the take-off, the bearing of body in the air and the entrance into the water.

FIG. 4.—FORWARD HEADER DIVE (RUNNING)

The Olympic committee composed a table listing the type of dives allowed, their description, and a value for each dive based on the difficulty of performance. These early tables comprised 14 dives from the high firm platform and 20 from the springboard, as compared with the 46 and 47 of mid-20th century.

To indicate the advances made in diving, it can best be described by comparing the dives of yesteryear with today's complex stunts. The report following the 4th Olympiad suggested elimination of the double somersault because it was believed that a diver could not control the execution of such numerous spins without chance of injury. Today, divers from most sections of the world are confidently somersaulting 2½ times backward and 3½ times forward from both firm and springboard elevations. The combinations of spins and twists are often done, and a forward 1½ somersault is often combined with a double twist, performed with great skill and ease.

Beginning with the Olympic games of 1920, which excluded German athletes, U.S. divers dominated international competition. This supremacy can be credited to three U.S. coaches: Ernst Brandsten, an outstanding Swedish diver in the 1912 games whose chief contribution was his thoroughness in teaching fundamentals and his success in standardizing equipment; Fred Cady, a sports-minded artist whose sensitiveness to grace and poise had great influence; and Mike Peppe, a midwest coach who developed more national and international diving champions than any other coach. The combination of ideas and tuitions represented by such men as these produced U.S. diving champions, in all Olympic events after 1920 except for the men's 10-m. platform event in 1956 and both events in the women's diving competition in 1960.

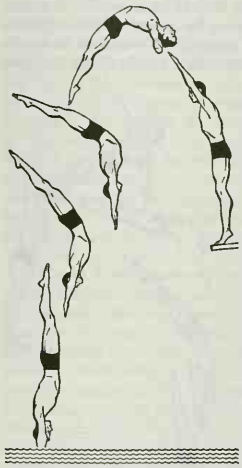
FIG. 5.—BACKWARD HEADER DIVE

The Groups of Competitive Dives.—Competitive dives are divided into five groups encompassing springboard dives and fixed platform dives, with the addition of arm stand dives done from fixed platforms. The first includes the forward dives (fig. 4), in which the person dives out away from the platform and rotates ½ turn to 3½ turns before entering the water. The second group comprises backward dives (fig. 5), in which the diver stands at the edge of a platform and rotates backward ½ turn to 2½ somersaults. The third group (fig. 6), the forward motion and reverse spin dives, is commonly called the reverse group. In this form of diving the diver can rotate in reverse from ½ turn to 2½ turns.



ILLUSTRATIONS FROM OFFICIAL A.A.U. SWIMMING HANDBOOK BY COURTESY OF AMATEUR ATHLETIC UNION OF UNITED STATES

FIG. 6.—HALF GAINER DIVE (RUNNING)

The fourth group is that of inward dives (fig. 7). In this category the diver stands on the outer edge of the platform and jumps backward with a forward rotation from ½ turn to 2½ somersaults. The fifth and last classification is that of twisting (fig. 8). In this movement the diver rotates the body on the long axis, from ½ twist to 2½ twists, while revolving on the short axis from ½ turn to 1½ somersaults. With the possibilities of combining all groups with twisting, it can easily be seen why the last grouping offers more dives than any other from which the diver can choose his optional dives.

The majority of dives included in the present roster may be executed in three distinct positions; namely, straight, pike or tuck. In the first position (straight), the body must be held extended, and no flexion at the hips or knees is allowed. In the second position (pike), there may be a bend at the hips, with no knee flexion. In the third position (tuck), both the knees and hips are flexed and the position of the body resembles a ball. In all positions the feet must be pointed.

Diving Board.—The surfaces of diving boards, whether firm or flexible, must be covered with cocoa matting or some other nonskid material the full length of the run. Springboards may be made of wood, aluminum, steel or other resilient material. Standard equipment for springboards is the adjustable fulcrum, which enables the diver to adjust the flexibility of the board to his liking.

7. Channel Swimming.—Much interest has centred in the many attempts to swim across the English channel. The first recorded attempt was made on Aug. 24, 1872, by J. B. Johnson, who started from Dover but remained in the water only 65 min. On Aug. 12, 1875, Capt. Matthew Webb made his first attempt. He started from Dover and remained in the water 6 hr. 49 min., until the weather became too rough for him to continue. It is estimated that he was about 13½ mi. across when he had to give up. On Aug. 24 and 25, 1875, Webb swam the channel, diving from the Admiralty pier, Dover, and touching Calais sands after swimming for 21 hr. 45 min. The accomplish-

ment created a great sensation in England, and many swimmers have since repeated Webb's performance.

8. **Open-Water Swimming.**—The enjoyment and pleasure derived from bathing and swimming in salt or lake waters make it among the most popular of all sports and recreational activities the world over, but proper caution in water activities should be taken.

Swimming in unsupervised areas should be avoided. A person should never swim outward from shore for any great distance without an accompanying boat. If he is caught in sea grass or weeds, he should not struggle against it but rather gently shake the arms and legs until the grass floats free.

Tides, riptides and undertow must be noted in offshore swimming, and knowledge of safety skills in such circumstances can save lives. Riptides are riverlike masses of water caused by the contour of the bottom. They are bound on both sides by eddies that swing back toward shore. A swimmer should never attempt to fight a riptide but rather swim diagonally with it and to its edge, then swing into the eddy and be carried in toward shore. Undertow or backwash is simply the receding portion of the water that has been carried in by the breakers. Because of its movement outward from the shore, it is very disconcerting. Fortunately the water travels in two directions at two levels. The upper level travels inward and the swimmer should push off the bottom and emerge at the surface and go with the breakers toward shore.

FIG. 8.—HALF-TWIST, FORWARD DIVE (RUNNING)

Tides may cause currents running diagonally toward the beach, and the best procedure is to swim across or with them until shallow water is reached.

Due to the increased popularity of such activities as sailing, boating, skin diving, underwater spear fishing, water skiing and surfboarding, more people are taking to the open water as a form of recreation. A large percentage of drownings could be prevented if each person exercised caution and gained a thorough understanding of his own abilities before engaging in these sports.

For Olympic records in all aquatic events *see* OLYMPIC GAMES. *See* also DROWNING AND LIFESAVING; WATER POLO.

BIBLIOGRAPHY.—The literature on the subject of swimming is considerable; the most useful work of general reference is Ralph Thomas' (1904), which contains a bibliography from the earliest time. Other chief works on the technique of swimming that may be mentioned are: Thevenot, *The Art of Swimming* (1789); Steedman, *Manual of Swimming* (Melbourne, 1867); W. Wilson, *The Swimming Instructor* (1883); A. Sinclair and W. Henry, *Swimming* (1893); C. M. Daniels, L. de B. Handley and O. Wahle, *How to Swim and Save Life* (1907); H. R. Austin, *How to Swim* (1914); L. de B. Handley, *Swimming and Watermanship* (New York, 1918); R. J. H. Kiphuth, *Swimming* (New York, 1942); Frances A. Greenwood, *Bibliography of Swimming* (New York, 1940); T. K. Cureton, *How to Teach Swimming and Diving* (New York, 1934); U.S. Naval Institute, *Swimming* (Annapolis, Md., 1944); R. J. H. Kiphuth and H. M. Burke, *Basic Swimming* (New Haven, Conn., 1950; London, 1951); John A. Torney, Jr., *Swimming* (New York, London, 1950); D. A. Armbruster and L. E. Morehouse, *Swimming and Diving*, 2nd ed. (St. Louis, 1950); Max Madders (ed.), *Swimming: the Official Coaching Book of the E.S.S.A.* (London, 1951); *Handbook of the Amateur Swimming Association* (annually); *Amateur Athletic Union of the United States Official Swimming, Water Polo and Diving Rules* (annually); National Collegiate Athletic Association, *Official NCAA Swimming Guide* (annually).

(L. DE. B. H.; R. J. H. K.; K. B. ML.)

SWINBURNE, ALGERNON CHARLES (1837–1909), English poet and critic, was born in London on April 5, 1837. He was the son of Admiral Charles Henry Swinburne (of an old Northumbrian family) and of Lady Jane Henrietta, a daughter of George, 3rd earl of Ashburnham. It may almost be said to have been by accident that Swinburne owned London for his birthplace, since he was removed from it immediately, and always felt a cordial dislike for the surroundings and influences of life in the heart of a great city. His own childhood was spent in a very different environment. His grandfather, Sir John Edward Swinburne, bart., owned an estate in Northumberland, and his father, the admiral, bought a beautiful spot between Ventnor and Niton in the Isle of Wight, called East Dene, together with a strip of undercliff known as the Landslip. The two homes were in a sense amalgamated. Sir Edward used to spend half the year in the Isle of Wight, and the admiral's family shared his northern home for the other half; so that the poet's earliest recollections took the form of strangely contrasted emotions, inspired on the one hand by the bleak north, and on the other by the luxuriant and tepid south. Of the two, the influences of the island are, perhaps naturally, the stronger in his poetry; and many of his most beautiful pieces were actually written at the Orchard, an exquisite spot by Niton bay, which belonged to relatives of the poet, and at which he was a constant visitor.

After some years of private tuition, Swinburne was sent to Eton, where he remained for five years, proceeding to Balliol college, Oxford, in 1857. He was three years at the university, but left without taking a degree. Clearly he must have cultivated while there his passionate and altogether unacademic love for the literature of Greece; but his undergraduate career was unattended by university successes, beyond the Taylorian prize for French and Italian, which he gained in 1858. He contributed to the "Underground Papers," published during his first year, under the editorship of John Nichol, and he wrote a good deal of poetry from time to time, but his name was probably regarded without much favour by the college authorities. He took a second class in classical moderations in 1858, but his name does not occur in any of the "final" honour schools. Jowett was his firm friend after he left Oxford, and Swinburne visited him repeatedly at the seaside and in the country.

He left Oxford in 1860, and in the same year published the two dramas, *The Queen Mother* and *Rosamond*, a wonderful performance for so young a poet, fuller of dramatic energy than most of his later plays, and rich in harmonies of blank verse.

After spending some time with the Bell Scotts at Newcastle, Swinburne came to London, and began the intimate friendship with D. G. Rossetti which was to last for the next ten years. In 1861 he was introduced to Monckton Milnes (Lord Houghton, *q.v.*), who took an interest in his work and invited him to Fryston. There Swinburne created an unforgettable impression in the brilliant circle which gathered there, by his wide and varied acquaintance with ancient and modern literature and his astonishing memory. In 1862 he met Meredith, and a review of one of Victor Hugo's books resulted in correspondence. In the autumn of that year he lived with Meredith and the Rossettis at 16 Cheyne Walk. Swinburne showed symptoms of something approaching epilepsy, and it was thought better that he should be with friends. In 1864 he made a tour in France and Italy. At Florence he met Mrs. Gaskell and Walter Landor. For Landor he had a great admiration, but their meetings were few and short. On his return to London he took lodgings in Dorset street, where he made his home for many years.

In 1865 appeared the lyrical tragedy of *Atalanta in Calydon*, followed by *Chastelard*, and the famous *Poems and Ballads* in 1866. The *Poems and Ballads* were vehemently attacked, but *Dolores* and *Faustine* were on everyone's lips: as a poet of the time has said, "We all went about chanting to one another these new, astonishing melodies." By the close of his 30th year, in spite of hostility and detraction, Swinburne had placed himself in the highest rank of contemporary poets, and had even established himself as leader of a choir of singers to whom he was at once master and prophet.

Meanwhile, his life was disturbed by domestic sorrow. A favourite sister died at East Dene, and was buried in the churchyard of Bonchurch. Her loss overwhelmed Admiral Swinburne with grief, and he could no longer tolerate the house that was so

full of tender memories. So the family moved to Holmwood, in the Thames Valley, near Reading. Swinburne entered on a course of gaiety in London which seriously affected his health and alarmed his friends. At the same time he saw much of the Pre-Raphaelite movement, and for the next few years he was involved in a rush of fresh emotions and rapidly changing loyalties.

Works.—It is indeed necessary to any appreciation of Swinburne's genius that one should understand that his inspiration was almost invariably derivative. His first book is deliberately Shakespearian in design and expression; the *Atalanta,* of course, is equally deliberate in its pursuit of the Hellenic spirit. Then, with a wider swing of the pendulum, he recedes, in *Poems and Ballads,* to the example of Baudelaire and of the Pre-Raphaelites themselves; with the *Song of Italy* (1867) he is drawing towards the revolt of Mazzini (whom he had met at the house of George Howard, afterwards earl of Carlisle); by the time *Songs before Sunrise* are completed (in 1871) he is altogether under the influence of Victor Hugo, while Rome has become to him "first name of the world's names." But, if Swinburne's inspiration was derivative, his manner was in no sense imitative; he brought to poetry a spirit entirely his own, and a method even more individual than his spirit. It is well to distinguish clearly between the influences which touched him and the original, personal fashion in which he assumed those influences, and made them his own. The spirit of Swinburne's muse was always a spirit of revolution. In *Poems and Ballads* the revolt is against moral conventions and restraints; in *Songs before Sunrise* the arena of the contest is no longer only the sensual sphere, but the political and the ecclesiastical. The detestation of kings and priests, which marked so much of the work of his maturity, is now in full swing, and Swinburne's language is sometimes tinged with extravagance and an almost virulent animosity.

With *Bothwell* (1874) he returned to drama and the story of Mary Stuart. The play has fine scenes and is burning with poetry, but its length transcends all possibilities of harmonious unity. *Erechtheus* (1876) was a return to the Greek inspiration of *Atalanta;* and then in the second series of *Poems and Ballads* (1878) the French influence is seen to be at work, and Victor Hugo begins to hold alone the place possessed, at different times, by Baudelaire and Mazzini. At this time Swinburne's energy was at fever height; in 1879 he published his eloquent *Study of Shakespeare* and *Poems and Ballads* (second series) and in 1880 no fewer than three volumes, *The Modern Heptalogia,* a brilliant anonymous essay in parody, *Songs of the Springtides,* and *Studies in Song.* It was shortly after this date that Swinburne's friendship for Theodore Watts-Dunton (then Theodore Watts) grew into one of brotherly intimacy. After 1880 Swinburne's life remained without disturbing event, devoted entirely to the pursuit of literature in peace and leisure.

The conclusion of the Elizabethan trilogy, *Mary Stuart,* was published in 1881, and in the following year *Tristram of Lyonesse,* a wonderfully individual contribution to the modern treatment of the Arthurian legend, in which the heroic couplet is made to assume opulent, romantic cadences of which it had hitherto seemed incapable. Among the publications of the next few years must be mentioned *A Century of Roundells,* 1883; *A Midsummer Holiday,* 1884; and *Miscellanies,* 1886. The current of his poetry, indeed, continued unchecked; and though it would be vain to pretend that he added greatly either to the range of his subjects or to the fecundity of his versification, it is at least true that his melody was unbroken, and his resplendent torrent of words inexhaustible. His *Marino Faliero* (1885) and *Locrine* (1887) have passages of power and intensity unsurpassed in any of his earlier work, and the rich metrical effects of *Astrophel* (1894) and *The Tale of Balin* (1896) are inferior in music and range to none but his own masterpieces. In 1899 appeared his *Rosamund, Queen of the Lombards;* in 1908 his *Duke of Gandia;* and in 1904 was begun the publication of a collected edition of his poems and dramas in 11 volumes.

Later Years.—Meanwhile, in the autumn of 1879 the state of his health seriously alarmed his friends, and, with the consent of Lady Jane Swinburne, Watts-Dunton took him to live at his house, The Pines, Putney, where the last 30 years of his life were spent in complete retirement. He very rarely made the short journey into London, although his health was gradually restored. The friends visited Paris in 1882. In 1888 a flash of his old excitability involved him in a quarrel with Whistler.

Besides this wealth of poetry, Swinburne was active as a critic, and several volumes of fine impassioned prose testify to the variety and fluctuation of his literary allegiances. His *Note on Charlotte Brontë* (1877) must be read by every student of its subject; the *Study of Shakespeare* (1880)—followed in 1909 by *The Age of Shakespeare*—is full of vigorous and arresting thought, and many of his scattered essays are rich in suggestion and appreciation. His studies of Elizabethan literature are, indeed, full of "the noble tribute of praise," and no contemporary critic did so much to revive an interest in that wonderful period of dramatic recrudescence, the side-issues of which have been generally somewhat obscured by the pervading and dominating genius of Shakespeare. His prose work also includes an early novel in the form of letters, *Love's Cross-currents,* which had appeared serially in the Tatler and was revised for publication in 1905.

Place in Literature.—The service which Swinburne rendered to the English language as a vehicle for lyrical effect is simply incalculable. He revolutionized the entire scheme of English prosody. Nor was his singular vogue due only to this extraordinary metrical ingenuity. The effect of his artistic personality was in itself intoxicating, even delirious. He was the poet of youth insurgent against all the restraints of conventionality and custom. The young lover of poetry, when first he encounters Swinburne's influence, is almost bound to be swept away by it; the wild, extravagant license, the apparent sincerity, the vigour and the verve, cry directly to the aspirations of youth like a clarion in the wilderness. But, while this is inevitable, it is also true that the critical lover of poetry outgrows an unquestioning allegiance to the Swinburnian mood more quickly than any other of the diverse emotions aroused by the study of the great poets. It is impossible to acquit his poetry entirely of the charge of an animalism which wars against the higher issues of the spirit—an animalism sometimes of love, sometimes of hatred, but, in both extremes, out of centre and harmony.

Yet, when everything has been said that can be said against the unaesthetic violences of the poet's excesses, his service to contemporary poetry outweighed all disadvantages. No one did more to free English literature from the shackles of formalism; no one, among his contemporaries, pursued the poetic calling with so sincere and resplendent an allegiance to the claims of absolute and unadulterated poetry. Some English poets have turned preachers; others have been seduced by the attractions of philosophy; but Swinburne always remained an artist absorbed in a lyrical ecstasy, a singer and not a seer. His personality was among the most potent of his time, and his artistic influence was both inspiring and beneficent. He died at Putney on April 10, 1909.

(E. G.; X.)

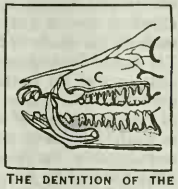
SWINDON, a municipal borough and parliamentary division of north Wiltshire, England, 78 mi. W. of London by road. Pop. (1951) 68,932. Area 9.9 sq.mi. Until 1841 it was a small market town (now Old Swindon) with a population of less than 2,000, but after the Great Western railway had built its main engineering works to the north the population rapidly increased to 45,000, and in 1900 it received its charter. More than 21,000 people are employed in the railway works and other industries include engineering, clothing and tobacco. Under the Town Development act, 1952, provisional approval was obtained from the ministry of housing and local government to accept overspill population and industry from the Greater London area. Planning approval was

given to expand the population to 92,000 within the existing borough boundaries and a 75-ac. trading estate has been developed close to the Swindon-Gloucester railway. In 1947 the first municipally owned arts centre in the country was opened, combining a small concert hall, a stage and an art gallery.

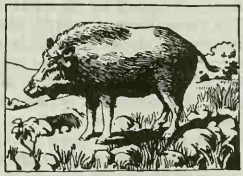
SWINE, a name applied to the domestic pig, but also used to include its wild relatives. The animals constitute the family Suidae (*see* ARTIODACTYLA). The swine are found only in the old world. They are characterized by elongated head and mobile snout, with an expanded, truncate, terminal surface in which the nostrils open; narrow feet with four toes, the outer pair not reaching the ground when walking. The canines in both jaws curve upward, forming large tusks, best developed in boars. The hair is coarse and bristly, while the skin is thick, underlaid by thick fat. The tail is moderately long, generally tufted.



THE DENTITION OF THE BOAR. 12 INCISORS, 4 CANINES, 16 PREMOLARS AND 12 MOLARS: TOTAL 44

The typical genus *Sus* is exemplified by the domesticated pigs (*see* PIG) and the wild boar. (*See* BOAR.) Allied to these are the pygmy hog of Nepal (*Porcula salvania*), a little larger than a hare; and the African river hogs (*Potamochoerus*).

Linking these genera with the wart-hogs is the African *Hylochoerus*, a forest-dwelling form with a thick coat of coarse black hair. The remaining forms are the wart-hogs (*q.v.*) (*Phacochoerus*), and the babirusa (*q.v.*). Extinct swine, some of gigantic size, are know from strata as far back as the Pliocene of Europe and Asia; many of these belonged to the genus *Sus*.



THE WILD BOAR (SUS SCROFA)

SWINE FEVER (HOG CHOLERA) is a devastating acute general infection of swine, caused by a virus, in which high fever and prostration are outstanding symptoms.

Natural infection results from immediate or mediate contagion. The disease may be acquired by healthy herds by the introduction of infected pigs. Exposure of swine in markets in infected areas is a common source of infection; so are vehicles and trucks in which pigs are conveyed from place to place; dealers, castrators who journey from farm to farm and attendants may serve as agencies whereby contagion is conveyed. Outbreaks are likely to recur in premises where the disease has existed previously, as the virus appears to retain its vitality for fairly long periods outside the animal body.

Since the virus may persist in uncooked garbage, Canada and most of the states of the U.S. require that garbage fed to swine be sterilized by cooking.

After an incubation period of four days to three weeks after exposure, the disease is ushered in by fever. Subsequent symptoms vary somewhat with the form the disease assumes. The animal has no appetite, is depressed, ill and separates itself from its companions; the conjunctivas are reddened and congested and may secrete a mucopurulent discharge; vomiting is common, and constipation and diarrhea are both met with; sometimes the feces become dysenteric and the odour is peculiar and disagreeable.

In many cases a skin rash develops, the parts principally involved being the region of the ears, the axilla, groin and the skin covering the abdominal area. The mucous membrane lining the mouth, fauces and pharynx may become inflamed; later ulcers form and become covered with a diphtheritic exudation. As a result the animal is unable to feed and respiration is difficult. The lungs may be the seat of pneumonic changes.

When this is the case the animal then has a short, dry and paroxysmal cough, a nasal discharge, difficulty in respiration and the other symptoms characteristic of acute lung infection. Gastritis and enteritis are common. The animal lies about and if compelled to move does so reluctantly and sometimes with a staggering gait and an arched back; later it is unable to rise and becomes comatose.

As in other acute septicemic diseases, a hyperacute form may develop and death supervene within a few days; or a less acute form may set in, with one or more groups of organs becoming involved.

A chronic type is also encountered, in which life drags on over a considerable period; the animal becomes more debilitated and emaciated and it remains a possible source of infection to other pigs.

Recovery occurs in some cases, the virulence and the mortality varying widely in different outbreaks.

Swine fever has a wide distribution throughout Europe, North America and Africa and is not uncommon in the British Isles. Canada controls the disease by slaughter of all hogs on infected premises, the cleansing and disinfection of premises and the serum treatment of all hogs in the vicinity of an outbreak. In the United States the average annual loss from swine fever, including vaccination costs, was estimated at mid-20th century to be from $20,000,000 to $30,000,000. It is the cause of 90% of deaths in swine.

The great toll that swine fever exacted in the United States stimulated efforts to develop vaccines. The first active vaccination method used, dating from 1907, was the simultaneous method, using active virus simultaneously with hyperimmune serum. By the early 1950s, about 90% of all hog vaccinations in the United States were by the simultaneous method. However, a strong movement developed against the use of virulent virus.

Modified and killed virus vaccines, neither of which could cause the disease, came to replace those made with active virus almost entirely, and eventual eradication of swine fever seemed possible. (A. R. S.; NA. BR.; X.)

SWINOUJSCIE (Ger. SWINEMÜNDE), a fishing port and seaside resort in the province of Koszalin, Poland, at the east end of the island of Usedom, and on the Swine river which connects the Stettiner Haff with the Baltic.

Swinemünde, which was founded in 1748, was fortified and raised to the dignity of a town by Frederick the Great in 1765. It was an important German naval base during World War II. About 70% of the city was destroyed during the war. Its population declined from 30,056 in 1939 to 5,771 in 1946. Population (1960) 16,900. It was transferred to Poland in 1945.

Manufactures include lumber, furniture and shipbuilding.

SWINTON, PHILIP CUNLIFFE-LISTER, 1st EARL OF (1884–), British statesman, was born on May 1, 1884, at Ayton, Yorkshire. The youngest son of Col. Lloyd-Greame, he assumed by royal warrant the name of Cunliffe-Lister in 1924. He was educated at Winchester and University college, Oxford, and was called to the bar in 1908.

During World War I he rose to the rank of major in the king's royal rifle corps. Elected Unionist member for Hendon in 1918, he was chairman of the labour committee of the war cabinet. He was parliamentary secretary to the board of trade and of the overseas trade department in the Lloyd George government; president of the board of trade, 1922–23, 1924–29 and 1931; colonial secretary, 1931–35; secretary of state for air, 1935–38; and minister for civil aviation, 1944–45.

He was created Viscount Swinton in Nov. 1935, and after he had served as secretary of state for commonwealth relations in the Churchill government 1952–55, was, at his retirement, created Baron Masham, of Ellington, and earl of Swinton.

SWINTON, an urban district in the West Riding of Yorkshire, England, 10½ mi. (17 km.) NE of Sheffield by road, at the junction of the Don navigation with the Dearne and Dove navigation. The population of Swinton (1961) was 13,420. Area 2.7 sq.mi. (7.0 sq.km.).

Formerly renowned for its Rockingham ware, it has coal mines, iron foundries, steel and glass works.

SWINTON AND PENDLEBURY, a municipal borough of Lancashire, England, 5 mi. NW of Manchester, contiguous with Salford. Pop. (1961) 40,470. Area 5.3 sq.mi. A great part of the Clifton rural area was added in 1933. Cotton spinning and weaving, coal mining, the manufacture of electric batteries, and

engineering are the chief industries. The town hall was opened in 1938. Anciently parts of Swinton were held by the Knights of the Order of the Hospital of St. John of Jerusalem. Swinton and Pendlebury, incorporated in 1934, forms with Eccles the Eccles parliamentary division of Lancashire, returning one member.

SWISS LITERATURE. From the point of view of language and literature the various nationalities of the Swiss confederation project into those of the neighbouring countries—Germany (Austria), France and Italy. This unusual aspect becomes particularly significant in relation to literary production before the existence or outside the boundaries of the *Ewiger Bund* (the Everlasting league) of 1291. Literatures produced exclusively in Switzerland are those written in the Raeto-Romance language or in one of the numerous varieties of local Swiss dialects. Latin literature, of course, chronologically precedes all the others. In the following survey all these literatures are considered both on their own account and as parts of a Swiss literature in an over-all sense.

Latin Swiss Literature.—The oldest document relating to what is now Switzerland was not produced within its territory, for the first notable description of Helvetia and the Helvetians is to be found in the first book of Caesar's *Commentarii*, commonly referred to as *Bellum Helveticum*. After the humanists rediscovered this text, it gradually rose in the historical consciousness of the Swiss to the rank and dignity of a Great Charter. Among the Latin chronicles of the middle ages the *Casus Sancti Galli*, written by Ekkehart IV in the 11th century, gives an impressive description of the highly developed culture of the abbey of St. Gall, founded by Irish Benedictines. Another chronicle, the *Johannis Vitodurani Chronicon*, contains the world picture as seen by a Franciscan of Winterthur in the first part of the 14th century. The Swiss humanists who expressed themselves in Latin devoted most of their prose and verse to a description of their own country; *e.g.*, Albrecht von Bonstetten, dean of the abbey of Einsiedeln, in his *Superioris Germanie Confoederationis descriptio* (1479) and Heinrich Loriti Glareanus in his *Helvetiae descriptio* (1514). An important position in the history of general linguistics is taken up by the Zürich polyhistorian Konrad Gesner, who in his *Mithridates* (1555) undertook a survey of all languages known to him. For three centuries to come the two volumes entitled *De Republica Helvetiorum* (1576) by the Zürich clergyman Josias Simler remained the standard work in the constitutional law and politics of the older Swiss confederation.

The final phase in Latin Swiss literature belongs to the Age of Reason and is largely connected with natural science. An outstanding example of it is the description of Switzerland given by the city physician of Zürich, J. J. Scheuchzer, and entitled *Uresiphoites helveticus sive itinera alpina tria* (1708). It was printed in London as a publication of the Royal society with the imprimatur of Isaac Newton.

German Swiss Literature.—In bulk, the most important literature of Switzerland is written in the German language. It first flourished in the age of the Minnesingers, of whom more than 30, *i.e.* practically one-fifth of the total number, lived on what is now Swiss territory. The identity of the Codex Manesse with the famous manuscript of that name in Heidelberg has traditionally been accepted. The Codex Manesse is an example of how specimens of prenational literature may be incorporated in a national literature: in the 18th century J. J. Bodmer was the first to have the Codex printed, and in the 19th century Gottfried Keller made it the subject of one of his *Züricher Novellen*. In this way the poetry of the Minnesingers became part of the history of Swiss letters.

The first literary productions with national characteristics were popular ballads and popular chronicles. The popular ballads commemorate especially the great battles fought by the Swiss from the 14th to the 16th century and later on. The most effective and influential of these is the ballad of William Tell, which through its moral and political aspects maintained an important position as a narrative and a play from the late 15th century onward. The popular chronicles, occasionally written on behalf of some local authority and often illustrated, flourished especially in Berne, Lucerne and Zürich. The most famous chronicle, however, was written by Giles (Aegidius) Tschudi, a leading magistrate of Glarus. The contents of his *Chronicon Helveticum* was widely known after its completion in the 16th century, although it was only printed in the years 1732 and 1734 at Basel. In it Johann von Schiller found the material for his drama *Wilhelm Tell* and Walter Scott the text for his translation of the ballad "The Battle of Sempach."

The reformation activities of Zwingli had only an indirect influence on literature. Zwingli himself wrote mainly in Latin. The so-called Zürich Bible was soon replaced by the Luther Bible, which actually made for a closer connection between the writings produced in Switzerland and in Germany. One of the most important results of the work done by Zwingli was that the Protestant majority of German-speaking Switzerland established a permanent connection with the Protestant parts of western Switzerland and with Protestant countries abroad. Thus one of the earliest Swiss accounts of England was produced by the Zürich clergyman and lexicographer Josua Maler (*c.* 1550), and in the 18th century the first German translations of Shakespeare were published in Zürich.

The beginning of 18th-century literature in German-speaking Switzerland is marked by the works of a Bernese poet and the end by those of a historian from Schaffhausen. The poetry of Albrecht von Haller, especially *Die Alpen* (1728), helped to bring about a new awareness in poetic experience in Germany and belongs to the earliest specimens of German poetry appreciated in France. Johannes von Müller's *Geschichten schweizerischer Eidgenossenschaft* (1786–1808), though a fragment, became the most representative piece of historical writing in German classicism and had a far-reaching influence on the style of historical writing in general. Between these two cornerstones appears what is occasionally referred to as the Zürich school of criticism. Two members of the "Carolinum," J. J. Bodmer and J. J. Breitinger, opposing the critical views of French rationalism and classicism, strongly promoted the reception and appreciation of English literature from John Milton to Thomas Percy in Germany. In this connection a revival of religious and national conceptions was prepared which had its special effect in the succeeding generations. Salomon Gessner had a European success with his revival of the idyll; for predominantly moral reasons J. K. Lavater turned to physiognomy and became one of its innovators; J. C. Hirzel surprised the reading public with the description of the village Socrates Kleinjogg. In importance, however, they were surpassed by Johann Heinrich Pestalozzi, who not only wrote the first village story in German, entitled *Lienhard und Gertrud* (1781), but included in it the nucleus of his later meditations, covering the entire field of the nature and destiny of man. It is indicative of the profound impression his ideas made on his contemporaries that his private institute of education at Yverdon was visited by philanthropists from all over Europe including, for instance, Robert Owen.

In the 19th century international fame and critical estimate at home did not always concur. Thus *The Swiss Family Robinson* (1812–27) by Johann David Wyss, and *Heidi* (1881) by Johanna Spyri are examples of a world-wide success though their purely literary merits were never considered very high at home. From the first to the second half of the 19th century the significance of German Swiss literature gradually increased. Berne produced its greatest novelist in the person of Jeremias Gotthelf (pseudonym for Albrecht Bitzius), whose epic power was combined with a profound knowledge of human nature. The series of his great novels, most of which describe village life, opened with the *Bauernspiegel oder Lebensgeschichte des Jeremias Gotthelf* (1837) and ended in the year of his death (1854) with *Erlebnisse eines Schuldenbauers*. Fiction and poetry are the fields in which the Zürich writers Gottfried Keller and Conrad Ferdinand Meyer achieved fame. Both realized their own possibilities and destinies comparatively late, a phenomenon frequently observed in the history of Swiss thought. Gottfried Keller reached the first peak of his creative powers with *Der grüne Heinrich* in 1854 when he was 35 and Meyer with his verse epic *Huttens letzte Tage* in 1871

when he was 46. Meyer drew upon the mountains and the princely courts of the past, and as a writer of fiction he succeeded in giving the Renaissance cult original expression. Keller in some of his best stories devoted himself to subjects corresponding to those of Cervantes and Shakespeare and brought the art of the Novelle to perfection. The love he had for his country appears in all shades from hymns of praise to pungent social criticism. His understanding of the human soul is seen at its height in the description of odd characters of both sexes and of unforgettably charming young women. His prose is both homely and delicate and is matched by the quality of his fundamentally human attitude. Many of his admirers believe that his work is the one real contribution of Switzerland to world literature. The importance of this period is emphasized by the writings of the Basel historian Jakob Burckhardt, whose statements about the past, the present and even the future have since become increasingly impressive and valid. His greatest disciple was Heinrich Wölfflin, who continued and completed that work of his master which was interrelated with the history of fine arts. The last poet of international repute was Carl Spitteler, who was distinguished for epics in verse and prose.

French Swiss Literature.—Though the French-speaking part of the Swiss population is only one-fifth of the total, the literature it has produced carries considerably more than the proportionate weight. This is due partly to the immigration of a number of highly talented Huguenot families, partly, though to a lesser degree, to the fact that occasionally writers born in the German-speaking part of the country would decide to express themselves in the French idiom. This applies especially to the Bernese. The beginnings of French Swiss literature proper coincide with the Reformation. Jean Cauvin from northern France fashioned Geneva into the *"cité de Calvin."* From Geneva he exercised his influence on French literature through his diction and on the Anglo-Saxon world through his theology. In this connection it is significant that one of the first important interpreters of England in France was the Bernese B. L. von Muralt, whose stay in England in 1694 resulted in his *Lettres sur les Anglais et les Français* (1725). His work was admired by J. J. Rousseau, the father of continental romanticism. The formative influences at work on the Genevese philosopher have usually been connected with the comparatively narrow strip of country between the Alps and the Jura. He was, however, not only a *"citoyen d'un état libre,"* as he described himself in the opening chapter of the *Contrat social*, but obviously shared the political and psychological conceptions of all Switzerland to such a degree that one is tempted to consider him its most brilliant publicity agent (*see*, for example, his *Considérations sur le gouvernement de Pologne*). Obviously Swiss subject material was dealt with by H. B. de Saussure, one of the founders of modern geology, in his *Voyages dans les Alpes* (1779–96).

At the beginning of the 19th century, however, French Swiss literature on the whole preferred international themes and was largely connected with the influential circle of Mme. de Staël, who was born in Paris but was of German and Swiss extraction. Of her books setting forth the qualities of the various nations of Europe the one entitled *De l'Allemagne* had the widest influence. Her friend Benjamin Constant, though less prolific, expressed himself all the more pointedly; his adaptation of Schiller's trilogy *Wallenstein* contains the memorable essay *Sur le théâtre allemand*. Another member of the circle of Mme. de Staël, who in her manor house on the Lake of Geneva entertained a great many of the leading intellectuals of western Europe, was J. C. L. S. de Sismondi, who made an important contribution to Italian history with his *Histoires des républiques italiennes du moyen-âge* (1807–18). Further there was C. V. de Bonstetten, fundamentally a European in outlook, especially in his book *L'homme du midi et l'homme du nord* (1824).

To a later development belong the humorous tales and sketches of Rodolphe Toepffer, depicting a more homely world (*La bibliothèque de mon oncle*, 1832), while the poems of Juste Olivier testify to a pronounced patriotism (*Poèmes suisses*, 1830). The criticism of Alexandre Vinet, based on an essentially personal interpretation of Christianity, found an echo both in Switzerland and in France. Toward the end of the 19th century a powerful international influence was exercised by the posthumous publication of the fragments of H. F. Amiel's *Journal intime* (1883), which caused Tolstoy to write a moving preface for its Russian translation. In his historical writings Philippe Monnier, in a manner reminiscent of Jakob Burckhardt, deals with Italy in the 15th and 18th centuries (*Le Quattrocento*, 1901, *Venise au 18. siècle*, 1907). C. F. Ramuz wrote strongly imaginative novels about life amongst vinegrowers and Alpine herdsmen (*Oeuvres complètes*, 1940–). Gonzague de Reynold, with a consistency hardly known before him, demonstrated the inward connection between German and French-speaking Switzerland in the 18th century and depicted the whole of his country in his *Cités et pays suisses*.

Italian Swiss Literature.—Only about 4% of the total population of Switzerland use Italian as their native language. Their home is in the Ticino country and in some of the southern Grisons valleys. It is thus unlikely that the literature of such a small group could exist without a strong and permanent relation to Italian literature proper. Since the 18th century there have been a few nationally distinct features in what is now often referred to as the Swiss Italianità. The themes of these minor writings devoted to poetry and fiction, natural science and history, economics and politics are fairly characteristic. As an exponent of the Age of Reason, Father Francesco Soave of Lugano translated John Locke and Salomon Gessner into Italian and, following the example of the latter, wrote his own *Novelle Morali* (1782), which since then have appeared in hundreds of editions and have also made the story of William Tell popular in Italy. A representative figure in the first half of the 19th century is Stefano Franscini, who in theory and practice helped to bring about the new unity of the Ticino country and to connect it with the spirit of the Swiss confederation. His main work, *La Svizzera Italiana* (1837–38), bears as a motto a quotation from Albrecht von Haller: "Alpibus quidem ad Italiam spectantibus ego plurimum boni spero" (The Alps looking toward Italy are my greatest hope). His *Nuova statistica della Svizzera* (1847) proved to be a particularly effective description of Switzerland in that period.

So far, undeniably the most outstanding poet and novelist of the Ticino country has been Francesco Chiesa. A convinced regionalist he combines a profound love of his country with an admiration for the great Lombard poets and thus creates the high literary standards necessary for the Italian-speaking part of Switzerland. His vast influence on his contemporaries has essentially contributed towards keeping the Italianità of his region intact (*Calliope*, 1907; *I viali d'oro*, 1911; *Tempo di marzo*, 1925). One of his disciples equally bent on exploring and interpreting his home country was Giuseppe Zoppi (*Leggende ticinesi*, 1928, and *Presento il mio Ticino*, 1933).

Raeto-Romance Literature.—The Raeto-Romance language was formerly spoken far beyond the boundaries of Switzerland; today it is only used in a few Grisons valleys. A treatise, published by the Grisons historian and philologist Joseph von Planta in the *Philosophical Transactions of the Royal Society of 1776*, made the existence of the language known to a wider public. Only recently, however, was it officially recognized. On Feb. 20, 1938, following a plebiscite of the whole country, Raeto-Romance, though represented by only 1% of the total population, was declared one of the four national languages of the Swiss confederation. Raeto-Romance literature was in its origins predominantly ecclesiastical and began in the middle ages. The Reformation gave it new impulses. There is a rich variety of popular songs, especially of the political kind. Owing to its geographical distribution Raeto-Romance literature is essentially regional in character. Nevertheless the anthologist Caspar Decurtins and the poet Peider Lansel achieved decidedly more than mere local fame in the 20th century.

Swiss Dialect Literature.—The fortunes of Swiss dialect literature vary according to the language situation in each respective section of the country. In the Ticino country dialect literature is being produced with much devotion, but so far seems to have been of little consequence. In the French-speaking part of the country the local dialects are on the wane and, consequently, so are dialect writings. The important instances of this sort of literature belong to past centuries such as the different Genevese ballads

commemorating the victory of the *Escalade* in 1602. International fame was achieved by the various *Ranz des vaches,* melodies sung or played on the horn by herdsmen and in one case taken down by Rousseau in his *Dictionnaire de musique* (1768).

At present dialect literature flourishes mainly in the German-speaking part of the country, chiefly because there the population, regardless of social rank and education, consistently sticks to the use of the dialect for everyday purposes. The existence of numerous local idioms might even produce an ever increasing variety of dialect writings. This, however, would be at cross purposes with the accepted determination of the writers and their reading public to remain on common ground with German literature as a whole, which explains why some of the best poets express themselves both in high German and in their dialect. Thus Adolf Frey published a volume of poems in the dialect of the Aargau (*Duss und underm Rafe,* 1891 and 1921) and Meinrad Lienert one in the dialect of Schwyz (*'s Heiwili,* 1908). There are vigorous novels in the Bernese dialect by Rudolf von Tavel, who began in 1907 with *Jä gäll, so geit's,* and by Simon Gfeller, who depicted life among the peasants of the Emmenthal beginning with *Heimisbach* (1911).

Patrimonium Helveticum.—Without detriment to their connections with European civilization many Swiss consider the existence of a sixfold national literature with deep satisfaction. They are perfectly aware of the perplexing problems it inevitably involves and even look upon them as an asset. Between the extremes of absolute diversity and absolute unity there is room for all aspects and expressions of thought and imagination. This is what the Swiss spirit of freedom fundamentally wills. A representative cultural centre—such as Florence once was for Italy and Paris still is for France—is inconceivable for Switzerland. Each group and even each individual expresses itself according to its character and region. Such a state of affairs may have its greatness, but it certainly also has its drawbacks and its dangers, which can only be overcome on the level of a vigorous national consciousness. So far this consciousness has proved adequate for the solution of the problems involved. A deteriorating structural change could only occur if the minorities were estranged from the confederate whole or if the majority forces were tempted to exploit their position regardless of tradition.

Although there is at present a trend for a slight shift in the numerical relationship of the different languages one cannot seriously speak of a peril to the well-established balance of the different cultures. On the contrary the fact that the underlying ideals are very much alive may produce further high lights of national integration. A development of over 1,000 years is at the basis of the literary life of Switzerland and will continue to shape what might be called an ever-growing *patrimonium Helveticum.* (F. E.; H. Sn.)

Contemporary Writers.—Swiss contemporary authors have found themselves inescapably confronted with two world wars, totalitarian revolutions, the triumphs of technical civilization and a growing disintegration of the great traditional values.

A considerable minority stick to the old values still current in the village and the small town, praising the good gifts of the earth (Heinrich Federer, 1866–1928; and Alfred Huggenberger). Others furnish antidotes to the conventional order of things and are alert to the stimuli of international modern thought. After 1914 Albert Steffen, Jakob Schaffner (1875–1944), Robert Faesi and others opened broader and deeper vistas of the individual and of nations. Marxist views are expressed by Hans Mühlestein and Jakob Bührer. On the other hand the complicated, highly strung modern individual preoccupies novelists like Monique Saint-Hélier and Kurt Guggenheim.

A wave of irrationalism has set free new forces in Swiss poetry. In some writers, a refined sense of form (Siegfried Lang) and the bold use of intuitive imagery (Albin Zollinger, 1895–1941, Werner Zemp, Silja Walter) are reminders of the nearness of C. G. Jung, the Swiss explorer of the unconscious. Religious thought in this epoch has been greatly influenced by the theology of Karl Barth and Emil Brunner. A promising, provocative playwright is Friedrich Dürrenmatt.

With a few exceptions (*e.g.,* the Zürich dramatist Max Frisch and the young Swiss Italian Felice Filippini) existentialism has had little chance with Swiss writers so far, but many of the best believe that the truth lies in a sort of holism, an interpenetration of both the forces of the native soil and the world at large, *e.g.,* the novelists Gustav Keckeis and Cecile Ines Loos and the poet Urs Martin Strub; whereas the novelist Meinrad Inglin and the playwright Caesar von Arx (1895–1949) stress the native element. A similar sense of many-sided relationships is an essential feature of the historic and literary essays of Gonzague de Reynold, Carl J. Burckhardt, Fritz Ernst and Max Rychner, representatives of a truly European Switzerland. (A. Bx.)

Bibliography.—R. Faesi, *Anthologia Helvetica* (Leipzig, 1921) is a collection in the six languages mentioned. Anthologies based on each of the four national languages are: E. Korrodi, *Geisteserbe der Schweiz,* 2nd ed. (Erlenbach-Zürich, 1943); C. Clerc, *Le génie du lieu* (Neuchâtel, 1929); *Scrittori della Svizzera italiana,* 2 vol. (Bellinzona, 1936); C. Descurtins, *Rätoromanische Chrestomathie,* 12 vol. (Erlangen, 1896–1919).

General histories: G. de Reynold, *Histoire littéraire de la Suisse au 18 siècle* (Lausanne, 1909); E. Jenny and V. Rossel, *Geschichte der schweizerischen Literatur,* 2 vol. (Bern, 1910); C. Clerc *et al., Littératures de la Suisse* (Paris, 1938).

German Swiss literature: J. Baechtold, *Geschichte der deutschen Literatur in der Schweiz* (Frauenfeld, 1892); J. Nadler, *Literaturgeschichte der deutschen Schweiz* (Zürich, 1932); E. Ermatinger, *Dichtung und Geistesleben der deutschen Schweiz* (Munich, 1933); O. von Greyerz, *Die Mundartdichtung der deutschen Schweiz* (Swiss German dialect literature) (Leipzig, 1924).

French Swiss literature: V. Rossel, *Histoire littéraire de la Suisse romande des origines à nos jours,* 2 vol. (Geneva, 1889, 1891); P. Godet, *Histoire littéraire de la Suisse française,* 2nd ed. (Paris, 1895); *see* also C. Clerc, "La Suisse romande" in J. Bédier and P. Hazard, *Histoire de la littérature française,* 2 vol., 2nd ed. (Paris, 1948, 1949).

Friederich, *Bibliography of Comparative Literature* (Chapel Hill, 1950); H. Weilenmann, *Die vielsprachige Schweiz* (Basle, 1925); F. Ernst, *Helvetia Mediatrix* (Zürich, 1939) and *European Switzerland Historically Considered* (Zürich, 1951).

SWITHUN (or Swithin), **SAINT** (d. 862), bishop of Winchester and patron saint of Winchester cathedral from the 10th to the 16th century. He is scarcely mentioned in any document of his own time. His death is entered in the *Anglo-Saxon Chronicle* under the year 861; and his signature is appended to several charters in Kemble's *Codex diplomaticus.* Of these charters three belong to 833, 838, 860–862. In the first the saint signs as "Swithunus presbyter regis Egberti," in the second as "Swithunus diaconus," and in the third as "Swithunus episcopus." Hence if the second charter be genuine the first must be spurious, and is so marked in Kemble.

More than 100 years later, when Dunstan and Ethelwold of Winchester were inaugurating their church reform, St. Swithun was adopted as patron of the restored church at Winchester, formerly dedicated to St. Peter and St. Paul. His body was transferred from its almost forgotten grave to Ethelwold's new basilica on July 15, 971, and according to contemporary writers, miracles accompanied the translation.

The revival of St. Swithun's fame gave rise to a mass of legendary literature. The so-called *Vitae Swithuni* of Lantfred and Wulstan, written about A.D. 1000, hardly contain any germ of biographical fact; and the earliest detailed authority is a biography ascribed to Gotzelin (*fl.* 1058–78). From this writer, who has perhaps preserved some fragments of genuine tradition, it is learned that St. Swithun was appointed bishop of Winchester under Aethelwulf. At his request Aethelwulf gave the tenth of his royal lands to the church. He died on July 2, 862, saying that he was not to be buried within the church but outside in "a vile and unworthy place."

William of Malmesbury adds that, as Bishop Alhstan of Sherborne was Aethelwulf's minister for temporal, so St. Swithun was for spiritual matters. The same chronicler uses a remarkable phrase in recording the bishop's prayer that his burial might be "ubi et pedibus praetereuntium et stillicidiis ex alto rorantibus

esset obnoxius." This expression has been taken as indicating that the well-known weather myth contained in the doggrel lines—

> St. Swithin's day if thou dost rain
> For forty days it will remain;
> St. Swithin's day if thou be fair
> For forty days 'twill rain na mair—

had already, in the 12th century, crystallized around the name of St. Swithun; but it is doubtful if the passage lends itself by any straining to this interpretation.

The so-called lives of St. Swithun written by Wulstan, Lantfred, and perhaps others toward the end of the 10th century may be found in the Bollandist *Acta sanctorum* (July), i, 321–327; Mabillon's *Acta SS. O. B.* vi, 70, etc., vii, 628, etc.; and J. Earle's *Life and Times of St. Swithun*, 59, etc. *See* also William of Malmesbury, *Gest. reg.*, i, 150, and *De gest. pont.* 160, 167, 179; Florence of Worcester, i, 168; T. Rudborne ap. Wharton's *Anglia sacra*, i, 287; T. D. Hardy's *Cat. of mss.*, i, 513–517; J. Brand's *Popular Antiquities;* R. Chambers's *Book of Days:* Ethelwulf's *Tithe Charters*, nearly all of which refer to St. Swithun in the body of the text, may be studied in Haddon and Stubbs's *Councils*, iii, 636–645.

SWITZERLAND (Ger. SCHWEIZ; Fr. SUISSE; It. SVIZZERA; Lat. HELVETIA) is a confederation or *Eidgenossenschaft* of 22 cantons (3 of which have half-cantons) with a republican and federal constitution. It is situated in central Europe and bounded north by Germany, east by Austria and the principality of Liechtenstein (included since 1924 in the Swiss customs and monetary union), southeast and south by Italy, and southwest, west and northwest by France.

PHYSICAL GEOGRAPHY

Switzerland extends between 45° 49′ and 47° 48′ 30″ N. lat., and from 5° 58′ to 10° 30′ E. long. It forms an oval-shaped mass of which the greatest length (west-southwest to east-northeast) is 226 mi., and the greatest breadth (north to south) is 137 mi. It has little or no physical unity, consisting as it does of numerous small districts, differing widely in language, religion, ethnology and customs, bound together in a political alliance, made originally for common defense.

The nation consists of three great river valleys (Rhône, Rhine and Aar), lying to the north of the main chain of the Alps and including within their Swiss basins all the region between the Alps and the Jura. In addition, the wedge-shaped canton of Ticino runs south from the St. Gotthard massif and drains to the Po, while in the extreme east a tongue of the Grisons canton drains northeast via the Engadine, into the Danube. The Rhône and Rhine valleys are shut off from that of the Aar by the great northern ridge of the Bernese Oberland and Tödi Alps. The Aar valley is wide and undulating, but the upper Rhine and Rhône have cut deep trenches in the structural depression which separates the great parallel chains. The main chain of the Alps provides the loftiest wholly-Swiss summit (15,200 ft.) in the crowning Dufourspitze of Monte Rosa, though the Dom (14,942 ft.) in the Mischabel range, immediately north of Monte Rosa, is the highest entirely Swiss mountain mass. The highest summit in the northern parallel ridge is the Finsteraarhorn (14,026 ft.) in the Bernese Oberland, while the lowest level within the confederation is on the Lago Maggiore (646 ft.).

The geological build of the Alps has been proved to be exceedingly complex; the contorted, folded, and even overfolded recent rocks have been fractured, exposing old crystalline cores to denudation; the Jura are much less complicated in their folding and in their exposures. Much of the central hummocky plain is covered with undisturbed very recent rocks of Oligocene and Miocene age, many of which are marine deposits formed at a period when an arm of the Mediterranean spread up the present Rhône course along the outer border of the Alps as far east as Austria. These deposits are concealed in many parts of the plain by the most recent glacial and alluvial accumulations.

The present confederation drains into the North sea, Mediterranean sea (direct), Adriatic sea and Black sea which, respectively, receive the Rhine, Rhône, Ticino-Po and Inn-Danube. The Swiss portions of their basins are approximately, in the order named: 11,160; 2,760; 1,360; and 660 sq.mi.

Many of its rivers, with their Alpine origin, tend to seasonal overflows which have necessitated artificial embankment. The most important control scheme was that of Conrad Escher of Zürich (later Conrad von der Linth) who in 1807–27 turned the turbulent Linth into Walensee, from which it emerges as a canalized stream. An earlier (1714) successful work was the diversion of the troublesome Kander into the Lake of Thun, where it is now placidly building an extensive fertile delta.

The lakes of Switzerland are very numerous: the largest, Geneva (southwest) and Constance (northeast) are on the frontiers and are not wholly Swiss. Neuchâtel (83 sq.mi.) is the largest wholly Swiss lake. About 16 sq.mi. at the north end of Lago Maggiore (82 sq.mi.) belongs to Switzerland; next in order of size are Lucerne, Zürich, about half of the Swiss-Italian Lake of Lugano (19 sq.mi.), Thun, Brienz, Morat, the Wallen and Sempach (5.5 sq.mi.); no others exceed 4 sq.mi. Eleven of these lakes are in the Aar basin, two (Maggiore and Lugano) are in the Po basin, and Geneva is the great Rhône filter. The lakes of the Swiss portion of the Inn basin are small; the largest are Sils (1.5 sq.mi.), and the still smaller, slightly lower and adjacent Silvaplana. Many small mountain lakes are of interest, such as the dreary Daubensee (7,264 ft. alt.) near to the Gemmi pass; the extremely beautiful Oeschinensee (5,223 ft. alt.) mirroring the snowy Blümlis Alp, and the remarkable, though sometimes empty Märjelensee (7,766 ft. alt.) on which float miniature icebergs from the Great Aletsch glacier.

Of the countless waterfalls in Switzerland those of the Rhine (near Schaffhausen), 100 ft. high, inclusive of rapids, and 340 ft. wide, are the grandest, but the most beautiful are of less volume and greater height, such as those of the Lauterbrunnen valley and particularly the Staubbach, a mere veil of water hanging in front of a precipice 980 ft. high.

Switzerland contains many more glaciers than the combined total for adjacent lands; the number is estimated at more than 1,000, but no exact computations are possible on account of numerous detached ice masses which may or may not rank as glaciers. Practically all of them are now in retreat, though they will long continue to feed all the important rivers and streams of Switzerland. They probably occupy 700 sq.mi., very unequally distributed; 11 of the cantons possess no glaciers. The greatest area is found in the Valais (more than half of the total area), followed by the Grisons and Berne (about one-sixth each); then by Uri, Glarus and Ticino (the last about 13 sq.mi.); the remaining cantons—Unterwalden, Vaud, St. Gallen, Schwyz and Appenzell have, in aggregate, a glacier area little superior to that of Ticino alone. The longest glacier in the main Alpine chain is the Gorner (9.25 mi.), but it is exceeded by the Great Aletsch (16.5 mi.) and by the Fiescher and the Unteraar (10 mi. each) which run down from the high eastern mountains of the Bernese Oberland.

Climate.—In an area such as Switzerland which extends through less than two degrees of latitude, climate will be influenced more particularly by differences of altitude, aspect and gradient; these show wide and surprisingly sudden variations, *e.g.*, Monte Rosa (15,217 ft. high) is only 30 mi. distant in a "straight" line from Lago Maggiore, with waters in the same latitude, but only 646 ft. in altitude. Great heights are characterized by (1) low barometer readings: Monte Rosa summit records about half sea-level pressure; hence the possibility of "mountain sickness"; (2) usually more brilliant sunshine and dry air, particularly in winter, producing sunburning and ice-dazzle, which in some subjects amounts to snow blindness; (3) much lower temperatures; among the Alps the average fall in temperature is about 1.2° F. on the south side and about 0.9° F. on the north side for each 330 ft. of ascent. The height of the Alpine crest and its main direction also profoundly influence the winds. In addition to local winds of certain higher levels which show a daily change of direction, downhill in the morning and uphill in the evening, there are other characteristic winds which are much less localized in their effects, as the southerly *föhn*, warm, dry and oppressive, which affects considerable areas in east Switzerland, particularly during spring and autumn; and the northerly *bise*, a cold wind experienced especially in Geneva. Switzerland's many climates are important, not only in Europe's playground generally, but also in the "nests of

sanatoria." Hence, climate and weather statistics have been carefully compiled for many stations.

January is the coldest month, the following averages in degrees F. being recorded: Basle (909 ft. alt.) 31.8; Altdorf (1,480 ft. alt.) 32.4; Davos (5,121 ft. alt.) 18.7; St. Gotthard (6,877 ft. alt.) 18.1; Säntis (8,202 ft. alt.) 16.2, while an unusually low average is from Bevers (5,610 ft. alt.) with 14.2. Precipitation (either rain or melted snow) shows wide variations, *e.g.*, Basle has 32.5 in. total annual precipitation; Altdorf, 49.0 in.; Davos, 35.7 in. and Säntis, 95.7 in. At several stations much of this falls as snow. On Säntis the precipitation is as snow from November to April inclusive, and only July and August have more rain than snow. Snow accumulates to a depth of 20 to 25 ft. at Bevers and upward of 45 ft. on Säntis. July is the hottest month, the average July records in degrees F. being: Basle 66.4, Altdorf 64.4, Davos 53.8, St. Gotthard 46.2, Säntis 41.0, Bevers 53.2. The range of 39.0° at Bevers tends to be extreme; Säntis, though cold, is much more equable, 24.8°. The snow line, showing considerable local variations, is about 9,000 ft. high on the western Alps, and about 10,500 ft. in the drier eastern mountains.

Vegetation.—Though Swiss vegetation is mainly central European in character, in some of the warm sheltered valleys Mediterranean types are found. The true alpine flora (plants growing above the tree limit) is akin to that of the Pyrenees rather than to either of the other elements (*see* Alps). Mediterranean species, found locally in the wide valley between the Jura and the Alps, in the Rhône valley in Valais, and on the southern slopes of the mountains running down to the Italian lakes, include vines, walnut trees, camellias, magnolias and palms. The lowlands and foothills are largely cultivated, and wherever possible land is farmed in the mountains. The natural climax vegetation of the mountain region, up to about 4,000 ft. on the northern slopes and 5,000 ft. or more on the southern, consists of deciduous trees such as oak, beech, ash and sycamore; but mixed forests of timber trees such as spruce, silver fir, larch and birch have been planted to a great extent in their place. The subalpine region covers the next 1,000 ft. or so where the pure coniferous forest (spruce, silver fir, larch and Scotch pine) are found. These merge into the scrub of the alpine region which contains dwarf pines and willows, juniper, bilberry, creeping azalea, mezereon, white dryas, rhododendrons, etc. This is also the region of the alpine pastures. Above about 6,500 ft. (where the summer lasts only five or six weeks) the flora is typically alpine, and cushion plants, mosses and lichens flourish among the bare rocks, screes and glaciers. Finally, between 8,000 ft. and 9,500 ft. comes the region of perpetual snow.

The alpine meadows are transformed into brilliant gardens in May, June and July. Among the first to blossom are crocuses, anemones, *Gentiana verna, Primula farinosa* and pheasant's eye narcissus, while on the higher slopes the edelweiss is in bloom. In June come St. Bruno's lily, orchids, campanulas, larkspurs and many others, followed by the martagon lily, oxeye daisy, etc. The alpine roses, *Rhododendron ferrugineum* and *R. hirsutum* (only found on limestone), clothe the sides of the Alps and Jura together with *Saponaria ocymoides, Helianthemum alpestre, Gentiana nivalis,* the alpine lily and many more. As soon as the meadows have been cut for hay the autumn crocus (*Colchicum autumnale*) appears.

Fauna.—In Switzerland the animals are protected and there is only a very short shooting season. Many of them, for example the chamois that lives high up in the mountains and the marmot that is found near the snow line, are alpine animals. Among the inhabitants of the forests are squirrels and foxes and woodpeckers, jays, tits and many other birds. Hares and field mice are common in the meadows. In the lakes and rivers there are trout and other fish, and salmon are found in the Aar, the Rhine and Lake Zürich. Among reptiles the viper is common. Insects are numerous: butterflies and moths abound in the meadows when the flowers are in bloom and ants are plentiful in the woods.

HISTORY

For indications of the prehistory and ancient history of what is now Switzerland *see* Alamanni; Burgundy; Celt; Geneva; Helvetii; La Tène; Raetia; Savoy, House of; Vindelicia; etc. The following pages treat of the history of the Swiss confederation from its origin to the present day.

The Swiss confederation forms a nation the patriotism of whose members is universally acknowledged; but Swiss history is very intricate and very local. A firm hold on a few guiding principles is therefore most desirable, and of these there are three which must always be borne in mind. (1) The first is the connection of Swiss history with that of the empire. Swiss history is largely the history of the drawing together of bits of each of the imperial kingdoms (Germany, Italy and Burgundy) for common defense against the Habsburgs; and when this dynasty had secured to itself the permanent possession of the empire, the Swiss league little by little won its independence of the empire, practically in 1499, formally in 1648. (2) The second is the German origin and nature of the confederation. Around a German nucleus (the three Forest districts or, as they are now called, cantons) there gradually gathered other German districts; and it was not until 1803 and 1815 that its French- and Italian-speaking cantons were raised to political equality with the German confederates. (3) The third is that Swiss history is a study in federalism. Based on the defensive alliances of 1291 and 1315 between the three Forest cantons, the confederation was enlarged by the admission of other districts and towns, all leagued with the original three members, but not necessarily with each other. Hence great difficulties are encountered in looking after common interests; the diet was merely an assembly of ambassadors with powers very strictly limited by their instructions, and there was no central executive authority. The whole constitutional history of the confederation is summed up in its transition to a federal state, which, while a single state in its foreign relations, in home matters maintains the more or less absolute independence of its members.

The League of 1291.—On Aug. 1, 1291, the men of the valley of Uri, the free community of the valley of Schwyz, and the association of the men of the lower valley or Nidwalden—Obwalden or the upper valley is not mentioned in the text, though its name was afterward added to the attached seal of Nidwalden—formed the Everlasting league for the purpose of self-defense against all who should attack or trouble them, a league which was expressly stated to be a confirmation of a former one. This league was the foundation of the Swiss confederation.

The legal and political conditions of each district were very different. (1) In 853 Louis the German granted all his lands in the *pagellus Uroniae* to the convent of SS. Felix and Regula in Zürich (the present Fraumünster) and exempted them from all jurisdiction save that of the king (*Reichsfreiheit*), so that though locally within the Zürichgau they were not subject to its count, the king's deputy. The abbey thus became possessed of the greater part of the valley of the Reuss between the present Devil's Bridge and the Lake of Lucerne, for the upper valley (Urseren) belonged at that time to the abbey of Disentis in the Rhine valley and did not become permanently allied with Uri until 1410. The privileged position of the abbey tenants gradually led the other men of the valley to "commend" themselves to the abbey. The important post of protector (*advocatus* or *vogt*) of the abbey was given to one family after another by the emperor; in 1218 the office was granted to the Habsburgs, but in 1231 the German king Henry VII bought it back in order to control the St. Gotthard pass, the valley thenceforward depending immediately on the king. (2) In Schwyz (first mentioned in 972) it is necessary to distinguish between the districts west and east of Steinen. In the former the land was in the hands of many nobles, among whom were the Habsburgs; in the latter there was, at the foot of the Mythen, a self-governing community of free men; both, however, were politically subject to the king's delegates, the counts of the Zürichgau, who after 1173 were the ever-advancing Habsburgs. But in 1240 the free community of Schwyz obtained from the emperor Frederick II a charter which removed them from the jurisdiction of the counts, placing them in immediate dependence

on the king, like the abbey men of Uri. In a few years, however, the Habsburgs contrived to dispense with this charter in practice. (3) In Unterwalden things were very different. The upper valley (Obwalden or Sarnen), like the lower (Nidwalden or Stans), formed part of the Zürichgau, while in both the soil was owned by many lay and ecclesiastical lords, among them being the Habsburgs and the Alsatian abbey of Murbach. Hence in this district there were privileged tenants, but no free community and no centre of unity; this explains why Obwalden and Nidwalden won their way upward so much more slowly than their neighbours in Uri and Schwyz.

The Habsburgs had risen steadily from the position of an unimportant family in the Aargau to that of powerful landed proprietors in Swabia and Alsace and had attained political importance as counts of the Zürichgau and Aargau. In one or both qualities the cadet or Laufenburg line, to which the family estates in the Forest cantons around the Lake of Lucerne had fallen on the division of the inheritance in 1232, seems to have exercised its legal rights in a harsh manner. In 1240 the free men of Schwyz obtained protection from the emperor. It was natural that when, after the excommunication and deposition of Frederick II by Innocent IV in 1245, the head of the cadet line of Habsburg sided with the pope, some of the men of the Forest cantons should rally around the emperor. Schwyz joined Sarnen and Lucerne (though Uri and Obwalden supported the pope); and in 1247 the men of Schwyz, Sarnen and Lucerne were threatened by the pope with excommunication if they persisted in upholding the emperor and defying their hereditary lords the counts of Habsburg. The rapid decline of Frederick's cause soon enabled the Habsburgs to regain their authority in these districts. These incidents are the only foundation in fact of the legendary stories of Habsburg oppression told of and by a later age. After this temporary check the power of the Habsburgs continued to increase rapidly. In 1273 the head of the cadet line sold all his lands and rights in the Forest cantons to the head of the elder or Alsatian line, Rudolph, who a few months later was elected German king. He recognized the privileges of Uri but not those of Schwyz; and as he united in his person the characters of German king, count of the Zürichgau and landowner in the Forest cantons, the union of offices might be expected to result in a confusion of rights. On April 16, 1291, Rudolph bought from the abbey of Murbach in Alsace (of which he was advocate) all its rights over the town of Lucerne and the abbey estates in Unterwalden. It thus seemed probable that the other Forest cantons would be shut off from their natural means of communication with the outer world by way of the lake. Rudolph's death, on July 15 of the same year, cleared the way, and a fortnight later (Aug. 1) the Everlasting league was made between the men of Uri, Schwyz and Nidwalden for the purpose of self-defense against a common foe.

Morgarten and the League of 1315.—In the struggle for the empire, which extended over the years following the conclusion of the league of 1291, the confederates supported without exception the anti-Habsburg candidate. On Oct. 16, 1291, Uri and Schwyz allied themselves with Zürich and joined the general rising in Swabia against Albert, the new head of the house of Habsburg. It soon failed, but hopes revived when in 1292 Adolph of Nassau was chosen German king. In 1297 he confirmed to the free men of Schwyz their charter of 1240 and, strangely enough, confirmed the same charter to Uri, instead of their own of 1231. It is in his reign that the first recorded meeting of the *Landesgemeinde* (or legislative assembly) of Schwyz (1294) occurred. But in 1298 Albert of Habsburg himself was elected German king. His rule was strict and severe, though not oppressive. He did not indeed confirm the charters of Uri or of Schwyz, but he did not attack the ancient rights of the former, and in the latter he exercised his rights as a landowner and did not abuse his political rights as king or as count. In Unterwalden the two valleys were joined together (1304) under a common administrator (the local deputy of the count)—a great step forward to permanent union. The stories of Albert's tyranny in the Forest cantons are not heard of until two centuries later. His successor, Henry of Luxemburg, confirmed, on June 3, 1309, to Uri and Schwyz their charters of 1297 and, for some unknown reason, confirmed to Unterwalden all the liberties granted by his predecessor, though as a matter of fact none had been granted. This charter and the nomination of one royal bailiff to administer the three districts had the effect of placing them all in an identical political position, and that the most privileged yet given to any of them—the freedom of the free community of Schwyz. On June 13, 1311, Henry granted the request of Leopold I of Habsburg, who had accompanied him on his expedition to Rome, that Baron Eberhart of Bürglen and Count Frederick of Toggenburg should inquire into the precise rights of the Habsburgs in Alsace and in the Forest cantons with a view to restoring them. But no steps were taken to draw conclusions from this investigation.

On Henry's death in 1313 the men of Schwyz seized the opportunity for making a wanton attack on the great abbey of Einsiedeln, with which they had a long-standing quarrel as to rights of pasture. The abbot caused them to be excommunicated, and Leopold's brother Frederick of Habsburg (chosen king, as Frederick III, by a minority of the electors), who was the hereditary advocate of the abbey, placed them under the ban of the empire. His rival, Louis of Bavaria, to whom they appealed, removed the ban; whereupon Frederick issued a decree by which he restored to his family all their rights and possessions in *the three valleys* and Urseren and charged Leopold with the execution of this order. The confederates hastily made arrangements with Glarus, Urseren, Arth and Interlaken to protect themselves from attack on every side. Leopold collected a brilliant army at the Austrian town of Zug in order to attack Schwyz, while a body of troops was to take Unterwalden in the rear by way of the Brünig pass. On Nov. 15, 1315, Leopold moved forward along the shore of the Lake of Aegeri, intending to assail the town of Schwyz by climbing the slopes of Morgarten above the southeastern end of the lake. There they were awaited by the valiant band of the confederates, who utterly defeated them. Leopold fled in haste to Winterthur, and the attack by the Brünig was driven back by the men of Unterwalden. On Dec. 9, 1315, representatives of the victorious highlanders met at Brunnen, on the Lake of Lucerne and renewed the Everlasting league of 1291. In their main lines the two documents are very similar, the later being chiefly an expansion of the earlier. That of 1315 is in German (in contrast with that of 1291, which is in Latin) and has one or two striking clauses largely indebted to a decree issued by Zürich on July 24, 1291. None of the three districts or their dependents was to recognize a new lord without the consent and counsel of the rest. Strict obedience in all lawful matters was to be rendered to the rightful lord in each case, unless he attacked or wronged any of the confederates, in which case they were to be free from all obligations. No negotiations, so long as the "Länder" had no lord, were to be entered on with outside powers, save by common agreement of all. Louis solemnly recognized and confirmed the new league in 1316; and in 1318 a truce was concluded between the confederates and the Habsburgs. The lands and rights annexed belonging to the Habsburgs in the Forest cantons were fully recognized as they existed in the days of Henry of Luxemburg, and freedom of commerce was granted. But there was not one word about the political rights of the Habsburgs as counts of the Zürichgau and Aargau.

The League of Eight Members.—The name Switzerland (*Sweicz;* derived from Schwyz, which had always been the leader in the struggle) applied to the three Forest cantons as early as 1320 and extended to the confederation as a whole in 1352. But it was not until after Sempach (1386) that it came into popular use, and it did not form the official name of the confederation until 1803. This is in itself a proof of the great renown which the league won by its victory at Morgarten. Another is that as years passed other members were admitted to the privileges of the original alliance of the three Forest cantons. First to join the league (1332) was the neighbouring town of Lucerne, which had grown up around the monastery of St. Leodegar, Ludger or Leger (a cell of the great house of Murbach in Alsace) and had been sold to the Habsburgs in 1291. Its accession brought a new element into the pastoral association of the Forest cantons, which surrounded the entire Lake of Lucerne. Next came the ancient

town of Zürich in 1351, when it got the help of the Forest cantons and of Lucerne against the threat of an Austrian attack. The league was then advanced from the hilly country to the plains, though the terms of the treaty with Zürich did not bind it so closely to the confederates as in the other cases and hence rendered it possible for Zürich now and again to incline toward Austria in a fashion which did great hurt to its allies. In June 1352 the league was enlarged by the admission of Glarus and Zug. Glarus belonged to the monastery of Säckingen on the Rhine and the Habsburgs as advocates of the abbey claimed many rights over the valley, which, however, refused to admit them and joyfully received the confederates who came to its aid. However Glarus was placed on a lower footing than the other members of the league, being bound to obey their orders. Three weeks later the town and district of Zug, attacked by the league and abandoned by their Habsburg masters, joined the confederation. The immediate occasion of the union of these two districts had been a war begun by the Austrian duke Albert II against Zürich, and the peace of Sept. 1352 restored Glarus and Zug to the Habsburgs, who also regained their rights over Lucerne. Zug was won for good by a bold stroke of the men of Schwyz in 1364, but it was not until the day of Näfels (1388) that Glarus recovered its lost freedom. These temporary losses were, however, far outweighed by the entrance into the league in 1353 of the famous town of Berne. Founded in 1191 by Berchtold V of Zähringen, Berne had become a free imperial city in 1218 on the extinction of the Zähringen dynasty and made a treaty with the Forest cantons as early as 1323. In 1352 it had been forced to take part in the war against Zürich, but soon after the conclusion of peace entered the league as the ally of the three Forest cantons, being thus only indirectly joined to Lucerne and Zürich. The special importance of the accession of Berne was that the league began to spread to the west and so came into contact for the first time with the French-speaking land of Savoy. The league thus by the end of the 14th century numbered eight members, the fruits of Morgarten, and no further members were admitted until 1481, after the Burgundian war. But while each of the five new members was allied with the original nucleus—the three Forest cantons—these five were not directly allied to one another.

Sempach and the Aargau.—Soon afterward, the quarrels with Austria broke out afresh. Lucerne fretted much under the Austrian rule, received many Austrian subjects among its citizens and refused to pay custom duties to the Austrian bailiff at Rothenburg, on the ground that it had the right of free traffic. An attack on the customhouse at Rothenburg and the gift of the privileges of burghership to the discontented inhabitants of the little town of Sempach a short way off, so irritated Leopold III (who then held all the possessions of his house outside Austria) that he collected an army, with the intention of crushing his rebellious town. Lucerne meanwhile had summoned the other members of the league to its aid, and approximately 1,600 men of Uri, Schwyz, Unterwalden and Lucerne opposed the 6,000 which made up the Austrian army. The decisive fight took place on July 9, 1386, near Sempach. Leopold, with a large number of his followers, was slain and the Habsburg power within the borders of the confederation finally broken. Glarus at once rose in arms, but it was not until the expiration of the truce made after Sempach that Leopold's brother, Albert III of Austria, brought an army against Glarus and was defeated at Näfels (not far from Glarus) on April 9, 1388, by a handful of Glarus and Schwyz men.

In 1389 a peace of seven years was made, the confederates being secured in all their conquests; and on July 16, 1394, the peace was prolonged for 20 years (and again in 1412 for 50 years), various stipulations being made by which the long struggle of the league against the Habsburgs was finally crowned with success. By the peace of 1394 Glarus was freed on payment of £200 annually; Zug too was released from Habsburg rule. Schwyz was given the *advocatia* of the great abbey of Einsiedeln; Lucerne got the Entlebuch (finally in 1405), Sempach and Rothenburg; Berne and its ally Solothurn were confirmed in their conquests. Above all, the confederation as a whole was relieved from the overlordship of the Habsburgs, to whom, however, all their rights and dues as landed proprietors were expressly reserved, Berne, Zürich and Solothurn guaranteeing the maintenance of these rights and dues with power in case of need to call on the other confederates to support them by arms. Though the house of Habsburg entertained hopes of recovering its former rights, so that technically the treaties of 1389, 1394 and 1412 were but truces, it was finally to renounce forever all its feudal rights and privileges within the confederation by the Everlasting compact of 1474.

The victory at Sempach enabled the league to extend both its influence and its territory. Both the league and its individual members were able to take the offensive. In the 15th century each member increased and rounded off its territory, though it usually withheld political rights from the men of the newly acquired lands. It was in the same century that Appenzell, St. Gallen and the Upper Valais first became associated with the league, though they did not become full members for a long time—Appenzell in 1513, St. Gallen in 1803, the Valais in 1815. Above all, the 15th century saw the first attempt of the confederation to secure a footing south of the Alps.

In 1412 the treaty of 1394 between the league and the Habsburgs had been renewed for 50 years. When in 1415 the German king and future emperor Sigismund placed Duke Frederick IV of Austria under the ban of the empire, the league hesitated, because of their treaty of 1412, until Sigismund declared that this treaty did not release them from their obligations to the empire. In Sigismund's name, therefore, and by his special command, the different members of the league overran the extensive Habsburg possessions in the Aargau. The chief share fell to Berne, but certain districts (known as the *Freie Ämter* and the county of Baden) were joined together and governed as bailiwicks held in common by all members of the league (save Uri, busied in the south, and Berne, which had already secured the lion's share of the spoil for itself). This is the first case in which the league as a whole took up the position of rulers over districts which, though guaranteed in the enjoyment of their old rights, were nevertheless politically unfree.

First Italian Conquests.—As the natural policy of Berne was to seek to enlarge its borders at the expense of Austria and later of Savoy, so Uri, shut off by physical causes from extension in other directions, as steadily turned its eyes toward the south. In 1410 the valley of Urseren was finally joined to Uri, an acquisition which gave to Uri complete command over the St. Gotthard pass, long commercially important and henceforth useful for purposes of war and conquest. Already in 1403 Uri and Obwalden had occupied the long narrow upper Ticino valley on the south of the pass called the Val Leventina or Livinental; in 1410 the men of the same two lands, exasperated by the insults of the local lords, called on the other members of the league, and all jointly (except Berne) occupied the Val d'Ossola (Eschental) on the south side of the Simplon pass. Having lost this to Savoy in 1414, they obtained in 1416–17 the alliance of the men of the Upper Valais, then fighting for freedom, and thus regained the valley (1416). In 1419 Uri and Obwalden bought from its lord the town and district of Bellinzona. This rapid advance, however, did not meet with the approval of the duke of Milan, Filippo Maria Visconti; the confederates were not at one with regard to these southern conquests; Filippo Maria intrigued with them; and finally in 1426, by a payment of a large sum of money and the grant of certain commercial privileges, the Val Leventina, the Val d'Ossola and Bellinzona were formally restored to him.

The First Civil War.—The original contrasts between the social condition of the different members of the league became more marked when the period of conquest began. Quarrels and ill-feeling arose on the subject of the Aargau and the Italian conquests and a few years later ripened into a civil war, brought about by the dispute as to the succession to the lands of Frederick VII, count of Toggenburg, the last male representative of his house. Count Frederick's predecessors had greatly extended their domains, so that they took in not only the Toggenburg or upper valley of the Thur, but Uznach, Sargans, the Rhine valley between Feldkirch and Sargans, the Prättigau and the Davos valley. He himself, the last great feudal lord on the left bank of the Rhine, had

managed to secure his vast possessions by making treaties with several members of the league. His death (April 30, 1436) was the signal for the outbreak of strife. The Prättigau and Davos valley formed the League of the Ten Jurisdictions in Raetia, while Frederick's widow took sides with Zürich against Schwyz for different portions of the great inheritance which had been promised them. After being twice defeated, Zürich was forced in 1440 to buy peace by certain cessions to Schwyz, the general feeling of the confederates being opposed to Zürich, so that several of them went so far as to send men and arms to Schwyz. Zürich, however, was bitterly disappointed at these defeats and had recourse to the policy which it had adopted in 1356 and 1393—an alliance with Austria (concluded in 1442), which now held the imperial throne in the person of Frederick III (Frederick IV as German king). Though permissible according to the terms of Zürich's joining the league in 1351, this act caused the greatest irritation in the confederation, and civil war broke out. In 1443 the Zürich troops were completely defeated at St. Jakob on the Sihl, close under the walls of the city. Next year the city itself was long besieged. Frederick, unable to get help elsewhere, procured from Charles VII of France the dispatch of a body of Armagnac free lances (the Ecorcheurs), who came, 30,000 strong, under the dauphin Louis, plundering and harrying the land. At the very gates of the free imperial city of Basle the desperate resistance of a small body of confederates (1,200 to 1,500), until cut to pieces, checked the advance of the freebooters, who then returned whence they had come. Several small engagements ensued, Zürich declining to make peace because the confederates required, as the result of a solemn arbitration, the abandonment of the Austrian alliance. At length peace was concluded in 1450, the confederates restoring almost all the lands they had won from Zürich.

Waldshut and the Burgundian War.—Various communities such as the abbey and the city of St. Gallen (1451), Appenzell (1452), Schaffhausen (1454), Rottweil (1463) and Mulhouse (1466) now became allies or associates of the eight cantons, while a successful war secured Thurgau as a common lordship, administered by all the states, except Berne, in agreement (1461). In 1467 and 1468 Berne used various pretexts to secure control of the Aargau; and war followed in 1468, partly in order to maintain the continued independence of Mulhouse against Sigismund of Tirol, the emperor Frederick III's cousin, who had succeeded to the Habsburg lands on the Rhine and in Alsace on his father's death in 1439 (in the years immediately following Frederick had been acting as his guardian). The war was hurriedly ended in Aug. 1468 by the treaty of Waldshut, by which Sigismund was obliged to pay an indemnity of 10,000 gulden within a year, failing which he was to forfeit Waldshut and his possessions in the Black forest. Sigismund had no ready cash and his efforts to secure a loan led to an even greater war.

Louis XI of France refused to advance any money; but by the treaty of Saint-Omer (May 1469) Charles the Bold, duke of Burgundy, was willing to offer 50,000 gulden in cash in return for a pledge of the Austrian lands in Upper Alsace, Ferrette, the Black forest and the Rhenish towns of Waldshut, Säckingen, Rheinfelden and Laufenburg. Skilfully interpreting some permissive clauses of the treaty favourably to his own expansionist ambitions, Charles proceeded to occupy the whole of Upper Alsace. He appointed Peter von Hagenbach as his agent with instructions to redeem mortgages, repair fortifications and improve administration in a way that would permanently unite Alsace with the Burgundian territories. This threatened the empire, and Frederick III declared the treaty void; it also greatly perturbed Berne, whose prospects of expansion were greatly reduced. Further, Charles the Bold entered into an alliance with Savoy and with Milan and also threatened to occupy Mulhouse, closely associated with Berne.

One result was the formation of the Lower union in 1473 by Basle, Colmar, Mulhouse, Sélestat and Strasbourg; another, the Perpetual understanding of 1474 between Sigismund of Tirol and the Swiss, by which the former renounced any further territorial claims in Switzerland in return for promises of money to pay off his debts. Hagenbach was illegally arrested and executed in the spring of 1474—a deliberate act of defiance of Charles the Bold, who seemed to be fully occupied elsewhere. The Lower union, supported by Berne, attacked Héricourt (Nov. 1474) and Blamont (1475), Louis XI promising cash subsidies while the war continued. Inspired by Niklaus von Diesbach, this western and southern movement continued all through 1475, much of the Vaud and part of Savoy, including Grandson, Orbe, Echallens, Jougne, Morat, Avenches, Estavayer and Yverdon being occupied by the end of the year, the inhabitants of the Valais acting in collaboration with Berne to prevent any interference from the side of Milan. Enraged and even a little alarmed, Charles the Bold came south in person in 1476, occupying Grandson at the end of February and hanging its Bernese garrison. Berne had gathered a considerable force from many states of the confederation and from the Lower union for the relief of the castle: too late to effect this, they offered battle on March 2 at Grandson. Charles' faulty generalship in the face of a disciplined force of pikemen, whom he mistakenly despised as ignorant peasants, led to the rout but not to the destruction of the Burgundian army. The duke regrouped his forces at Lausanne and again advanced against Berne in June. His way was blocked by the castle of Morat, held by Adrian von Bubenberg and 2,000 Bernese. The threat to this position was sufficient to bring 20,000 Swiss to its defense; and the battle of Morat (June 22, 1476) ended in a complete Swiss victory. Charles was forced to fall back on Lorraine, whose ruler, René, had turned against him. At Nancy (Jan. 5, 1477) the duke was defeated and killed. The Burgundian lands devolved upon his daughter Mary; Louis XI of France secured the duchy of Burgundy; Savoy regained, with French help, a good deal of the Vaud; and a Swiss incursion into Franche-Comté failed to consolidate itself into a permanent occupation.

Fribourg and Solothurn Admitted.—Such unity as the Swiss had so far enjoyed had been based almost entirely on successful defense against external enemies. They had been, in fact, poor and apparently insignificant communities co-operating with difficulty for self-preservation. Their military prowess, nurtured by necessity, had made them potentially great: the latter part of the 15th century was the golden age of the mercenary soldier, and the Swiss had proved themselves the best available recruits. There was much money to be made by military service and, for the first time, prospects of lucrative employment opened to young men of valour. But the cessation of danger from outside and the lure of foreign gold were almost sufficient to turn friendly states into competitors. There was no constitution to hold them together, no common officers, seal, law courts, coinage or flag; there was a growing divergence of interest between the cities and the mountain-dwellers, as well as between east and west; there were numerous family feuds and endless local jealousies, culminating in disputes about the distribution of the booty taken in the Burgundian war and about the administration of the territories held in common, particularly the Thurgau. Fribourg and Solothurn were anxious to come within the circle of the confederation, but neither Zürich nor Lucerne was very anxious for their support, while the country districts were anxious to maintain their predominance over the cities. By 1481 these differences had become so exacerbated that all common purpose seemed at an end and civil war threatened. It was averted by the intervention at Stans of the mysterious and self-effacing hermit Nicholas Lowenbrügger (Nicholas von der Flüe or Bruder Klaus), who arranged the compromise which held the confederation together. By this *Stanser Verkommnis* the full sovereignty of the component states was maintained and reasserted, but each agreed to abstain from attempts to foment internal discord or separatist activity among the subjects of any other state; the confederate oath of union was to be renewed every five years; loot captured in war was to be divided proportionately among the actual participants in the campaign, but lands occupied were to be shared equally by the states involved. The ancient guarantees of mutual aid and assistance in time of war were renewed, and Fribourg and Solothurn were admitted as full sovereign members of the confederation.

Zürich and the Swabian War.—Zürich had grown steadily in power and influence after its readmission to full confederate

status in 1446. Its textile manufactures had increased and with them the influence of the guilds; the effective authority within the city was shared by the ancient aristocracy, the *Constafel*. Hans Waldmann (1436–89) was recruited to the one by apprenticeship and to the other by marriage; he took part in a number of campaigns, including the battle of Morat, and was equally successful in war, business, diplomacy and politics. Burgomaster in 1482, he became virtual dictator of the city, upholding the interests of the citizens against the peasants and turning the city itself into a community whose welfare, amusements, food and clothing were subjected to regulation and supervision. In 1489, however, Waldmann had to face an armed peasants' revolt, which led to a constitutional revolution and to his execution. The aristocracy of birth and of labour joined hands, and the possibility of Zürich's dictatorship extending to the confederation was averted. The struggle between the government and the peasants, however, was repeated with local variations in Schwyz, Unterwalden, Zug, Lucerne and St. Gallen, although in no instance did the country people secure all their hopes.

The temporary eclipse of Zürich was followed by the last attack from the north. The emperor Maximilian I, uniting in his own person Habsburg and Burgundian traditions, sought to extend alike the imperial prerogatives and the possessions of his house. In 1495 the imperial diet of Worms had put forth a revised constitution for the empire ensuring internal peace and common taxation and setting up an imperial chamber (*Reichskammergericht*) as a final court of appeal. The Swiss communities were technically imperial subjects and had reason to fear renewed Habsburg aggression. They were therefore anxious to renew the understanding with France—Charles VIII was opposing Maximilian in Italy and was ready to hire Swiss mercenaries—and unwilling to join the South German Swabian league for the maintenance of peace.

South of the ten states of which the confederation was now composed lay the Grisons. In Raetia many small separate communities had united into an Upper league, a League of God's House and a League of the Ten Jurisdictions, and the two former were in alliance with the Swiss confederation. In 1499 a boundary dispute between Tirol and the League of God's House had led to a Tirolese incursion into the Engadine and the Münsterthal and thus to war with Maximilian; the Swiss came to the help of their ally, the emperor took up the implied challenge and in 1499 there was fighting from Basle to Bormio. Battles raged at Hard, Bruderholz, Schwaderloh, Frastenz and, most notably, against Maximilian himself at Dornach. Everywhere Maximilian, as usual, was unsuccessful; and the peace of Basle, Sept. 22, 1499, mediated by Ludovico Sforza (il Moro) of Milan, ended the war. In fact, although not in name, it was the recognition of Swiss independence.

Basle, Schaffhausen and Appenzell Admitted.—Basle as a member of the Lower union had taken part in the Burgundian war with the Swiss and had learned the value of such co-operation: as an imperial city it evaded with difficulty an obligation to support Maximilian in the Swabian war, while the confederates obviously needed security in the northwest. The bishop of Basle was politically much less influential than he had formerly been; and on July 13, 1501, the state was admitted to the confederation. It was a notable addition, for the city was well fortified, strong, relatively wealthy, a home of scholarship with an active university and with an industrious and busy population. Schaffhausen, although smaller, was in much the same position: it had had much difficulty with local knightly landlords, it had sent men to help its Swiss neighbours since 1453 and been accepted by most as an ally; and it had firmly refused to join the Swabian league. It received the reward of full admission to the confederation on Aug. 10, 1501. Finally, on Dec. 17, 1513, a little reluctantly, Appenzell, which had been an ally rather especially closely associated with the confederation, was admitted to full membership and partnership. It was the last addition to the whole body, now 13 independent states, until the French Revolution, and it was accepted only because it helped to redress the balance of the "country" as against the "city" states.

The Milanese Campaigns.—The northern frontiers of the Italian states, especially Milan, were exceedingly ill-defined. The southern route through Uri over the St. Gotthard was of growing importance for trade and much used by the mercenaries hired for service in the Italian wars. The inhabitants of the Val Leventina renounced Milanese allegiance in 1475 and were upheld in 1478 by armed men from Uri and other Swiss states. Bellinzona was besieged but not taken, and at Giornico a small Swiss force defeated a much larger Milanese one. But Berne and the western states were not interested in this southward expansion and refused to support any further advances; and it was with some difficulty that in April 1503 Bellinzona and the Blenio valley were secured by Uri, Schwyz and Nidwalden from Louis XII (as duke of Milan) in return for help against Ludovico il Moro. There was, however, growing resentment felt at the expenditure of Swiss lives in fighting on behalf of strangers, and opinion was markedly divided about the continued value of the French alliance, especially when France controlled Milan. The greatest man in the Valais was Matthäus Schiner, bishop of Sion and a cardinal, who had turned against the French. In 1510 Schiner arranged for Swiss support of the Holy league formed by the masterful pope Julius II for the expulsion of the foreigner from Italy. After the death of Gaston de Foix at Ravenna in 1512 Swiss, papal and Venetian forces in co-operation were able to secure the removal of the French from the plains of Lombardy. Genoa regained a transitory independence, Maximilian Sforza, son of Ludovico il Moro, returned as duke of Milan and acquiesced in the occupation of Locarno, Lugano, Mendrisio and the Val d'Ossola by the confederates, while the Grisons secured the Valtellina, Bormio and Chiavenna. At Novara (1513) a fresh French army under Louis de La Trémoille was almost annihilated in a hard-fought battle, after which the Swiss penetrated into the duchy of Burgundy as far as Dijon but returned home when promised a substantial sum of money. Francis I renewed the French invasion of northern Italy in 1515. The division of interests between the eastern cantons (who were reluctant to leave the St. Gotthard route uncovered) and Berne (traditionally well-disposed to France), together with a growing dislike of mercenary service and an equally strong distrust of Cardinal Schiner, led to a division of forces. Berne, Fribourg, Solothurn and the Valais were bought off at Gallarate; and a truncated Swiss army, with Milanese and papal support, was defeated on Sept. 14, 1515, at Marignano (*q.v.*) with heavy losses. Francis I willingly agreed to easy terms in 1516 retaining the duchy of Milan but acknowledging all that the confederates and the Grisons had gained in the Bellinzona area except Domodossola and paying a considerable sum as well.

The Reformation.—Five dioceses—Basle, Lausanne, Sion, Chur and Constance—provided the spiritual framework for the ministrations of the church to the Swiss people. Neither the institutions nor the men were suited to the changing needs of the 16th century. The bishops were sometimes nonresident, sometimes incompetent, often, as absentee landlords, disliked. The parish priests were frequently ignorant and sometimes lazy or immoral. While there were no territorial princes, as in Germany, to benefit by a redistribution of church property, the considerable monastic lands were coveted by certain cities, and if there was little active opposition to the indulgence system which so enraged Martin Luther, there was little popular support for it either. Humanism could hardly impinge upon the lives and thoughts of peasant mountain dwellers, but contacts with Italy were easy and Basle became the home of Erasmus and Joannes Froben's printing press. All these things affected the career of Huldreich Zwingli (*q.v.*) (1484–1531) who became the most influential figure in the Swiss Reformation. A musical, intelligent boy of good peasant stock from the Toggenburg district he had taught classics at the University of Basle and had been parish priest at Glarus (1506) and at Einsiedeln (1516) and people's priest (*Leutpriest*) in the Zürich minster in 1518. He had been to Rome and with Swiss armies in the field, had studied widely in the Fathers and read the Bible in the original Hebrew and Greek. Experience had convinced him that mercenary service was harmful to his countrymen, and his Bible study and reading of the works of Erasmus had made him critical of the pope and opposed to indulgences.

In the all-important city of Zürich the pulpit, properly used, could be most influential, and on Jan. 2, 1519, Zwingli started a course of sermons on St. Matthew's Gospel such as had not been

heard in the minster before: his teaching was inevitably called Lutheran although it was, in fact, the independent outcome of his own thought and studies. In the same year there was plague in Zürich, which caused a revivalist movement. Next, in 1520, Zwingli was denouncing the compulsory payment of tithe to the canons. The city council then permitted the public preaching of the gospel, and in 1522 Zwingli formally challenged ecclesiastical authority by eating meat (sausage) during Lent. He also denounced clerical celibacy and married Anna Reinhard, setting out his convictions and theological standpoint in 67 conclusions, which were publicly debated in Zürich in 1523. Appealing to the Bible, he convinced his hearers; the Great minster was reformed, monks and nuns began to leave the cloister, the clergy to marry and the communion to be administered in both kinds, the income from church property being diverted to education or poor relief. Images were discountenanced, preaching encouraged, relics hidden or destroyed, monasteries dissolved and finally, in April 1525, the mass was superseded by a simple commemorative service. Zürich had thus by steady stages accepted the Reformation, and Zwingli was left almost as head of the state as well as religious leader. He set out his religious teaching in writing, issued a vernacular translation of the Bible, rejected the teaching of the Anabaptists (who were proscribed) and secured a permanent majority of supporters in the city council.

The Catholic states were by then seriously alarmed and made every effort to isolate the new teaching in Zürich and to prevent its extension even to the common lordships over which Zürich shared jurisdiction. It soon became apparent that religious and economic interests were likely to coincide; the strongly Catholic cantons were, generally, the rural mountainous areas, Uri, Schwyz, Zug, Unterwalden, Lucerne, Solothurn and Fribourg, while the city-dominated communities, Basle, Berne and Schaffhausen in particular, were lost to the old faith. The coherence of the confederation had been difficult to maintain in 1480: it proved almost impossible in 1529. In February of that year the Catholic communities, encouraged by pope and emperor, formed a separatist group known as the Christian union; Zürich then tried to force the pace by an armed campaign in June, but the western states, particularly Berne, were not interested, and the antagonists were singularly loath to kill one another. The first armistice at Kappel (June 24) was followed by an agreement to dissolve the Christian union, to allow freedom of worship in the common lordships and to decline further foreign pensions. But neither side kept the spirit of the agreement. Then, in Oct. 1529, the efforts of Philip of Hesse to unite the Protestants by bringing Luther and Zwingli together at Marburg conspicuously failed. By 1531, when an Italian adventurer attacked the Grisons, the Forest cantons could refuse to come to the help of a non-Catholic state and could complain that the evangelical faith was being forced on the Thurgau. Choosing time and place with great skill, the five Catholic cantons declared war on Zürich at Lucerne on Oct. 4, 1531, and sent a force north to Kappel, where they met a hurriedly raised detachment of volunteers from Zürich led by Jorg Göldli and with Zwingli in person among them. The battle of Kappel (Oct. 11, 1531) resulted in a Catholic victory and in Zwingli's death.

Zürich thus lost the effective leadership of the confederation, which devolved, not very satisfactorily, upon Berne; the Catholics regained an appreciable amount of ground, so that when the Jesuits came they were in a strong position. For almost three centuries after 1531 religion so divided the Swiss people that co-operation was hardly possible. The rare diets of the whole confederation, necessary only for the administration of commonly owned territories, were brief and formal; the Protestant cities entered into cordial relations with England, Scotland, northern Germany and Scandinavia; the Catholic states were the willing agents of France, Spain and Austria on the rare occasions when these powers were found acting together. The wonder is that the confederation survived at all.

Geneva was not to be admitted as anything other than an allied state until 1815. Important strategically, it had entered into a pact of co-citizenship with Berne and Fribourg in 1526 in order to throw off the rule of its bishop and to prevent its absorption into the expanding and ambitious duchy of Savoy. The Protestant faith was brought into the Vaud from France and preached by Guillaume Farel and Pierre Viret under the protection of Berne, which had already taken various parts of the Vaud into a kind of protective custody. The Reformers were successful in 1535, after the usual public disputation, in inducing the independent city council of Geneva to forbid the public celebration of the mass. Threatened by their former bishop and by Savoy, the Genevans appealed to Berne, and a Bernese force under Hans Franz Nägeli overran the Vaud, occupied Lausanne and brought temporary security to Geneva. At this juncture John Calvin, who in 1536 had published at Basle his definitive *Christianae Religionis Institutio* came to Geneva and, not without some setbacks, soon made that city the centre of an active and independent religious teaching. Calvinist doctrine was explicit and logical, the duties of the Christian household were clearly prescribed, attendance at church, particularly at sermons, was enforced, sumptuary laws were enacted by the city, an excellent system of schools established and ministers of religion were chosen with the greatest care for their character and capacity. By the agreement of Zürich (*Consensus Tigurinus*), made with Heinrich Bullinger in 1549, Calvinism became the creed of the whole of Protestant Switzerland. The Catholic cantons would not agree to the inclusion of Geneva in the confederation so that the city had to rely upon the alliance with Berne, upon the desire of the communities of the Valais that Savoyard aggression should be restrained, and upon the obvious interest of France in a friendly neutral at such a strategically important point. Savoy was to make a last attempt to capture Geneva by surprise in 1602: this failed, and the city was never again in serious danger until it was annexed to France in 1798.

The Counter-Reformation and the Valtellina.—Charles Borromeo (*q.v.*) became archbishop of Milan in 1565, and much of southern Switzerland lay within his province. He was determined to stamp out the new faith wherever possible even if this meant straining the law and peace-agreements; he set a personal example of piety and of activity, visiting Einsiedeln and encouraging active Catholic conversion wherever possible. From the Swiss college at Milan, which he founded, and from the Jesuit houses missionaries came north; but the Protestants expelled from Locarno found a place of refuge in Zürich, and the Inquisition found little support even in the Catholic cantons. However, the nomination of a permanent papal nuncio was welcomed, and Lucerne and Fribourg gladly received Jesuit colleges. The historian Giles Tschudi, by a well-managed war, the so-called Tschudikrieg (1559–64), and through French and papal mediation, got the decrees of the Council of Trent enforced in Glarus, with the ultimate elimination of the Zwinglians; and Appenzell between 1579 and 1597 was subjected to an intensive process of reconversion which was so successful that the canton split into the two halves, Ausser Rhoden and Inner Rhoden (it thus remained politically impotent until 1848, and the division is still operative). Lucerne not only became the centre of Catholic Switzerland but it was also represented in France, during the Wars of Religion, by Ludwig Pfyffer (d. 1594) and it was the chief component of the Golden league which supported Philip II of Spain. Melchior Lussy (d. 1606) of Nidwalden not only advanced this cause by his skilful diplomacy, making himself very wealthy in the process, but he also secured the confidence of the pope and averted the threatened entire dissolution of the confederation.

The loosely united communities (Grey league, League of the Ten Jurisdictions, League of God's House) known as the Grisons, two-thirds Reformed, one-third Catholic, controlled the important eastern passes, which were of interest alike to Milan and to Venice. Milan was under Spanish control and jealous of its ancient commercial and territorial rival Venice, which in 1603 had secured the friendship of the Grisons partly through the powerful Planta family. The Valtellina (*q.v.*) was governed by the Grisons and inhabited by Catholics; its roads formed the most convenient link between Milan and Austria. Habsburg allies whose co-operation was unwelcome to France. A revolt in the Valtellina in 1620 led to Spanish support for the inhabitants against their northern masters and to successful Austrian intervention. The treaty of Mon-

zon (1626) called in the pope as a third party and led to further disputes, fomented by the local patriot, pastor, politician and pervert Georg Jenatsch (*q.v.*) and ended by a return to the *status quo* in 1639, with the Valtellina restored to Grisons sovereignty but with the Catholic rights markedly reinforced.

The Thirty Years' War.—All Switzerland was interested in the Bohemian war of 1618, which grew to a conflict that involved every great power on the continent, but the religious division in the confederation effectually prevented any corporate action. This was advantageous, for a Habsburg victory might have meant a renewal of Habsburg claims or an enforcement of the Edict of Restitution (whereby the Catholics recovered lost ecclesiastical lands), while a decisive Swedish triumph must have altered the balance of power in the confederation decisively. Many Swiss soldiers were hired by either side, and much material was sold to the combatants at a profit, while the necessities of frontier defense caused all the 13 states to come to a rare agreement in the Defensionale of Wil (1647). The frontiers would be defended against any aggressor and a mixed council of war of Protestant and Catholics would direct a force recruited from all parts of the confederation and its subjects and allies. The Defensionale was to be revised in 1668 and certain details were challenged later, but the acceptance of the principle of defense of neutrality was significant. The negotiation of the peace of Westphalia (1648) owed much to the indefatigable labours of Johann Rudolf Wettstein, burgomaster of Basle, and it was appropriate that this European instrument should take notice of the explicit renunciation by the emperor Ferdinand III of all imperial claims over Basle and the former Habsburg territories in Switzerland, an act followed by the abrogation of any claim by the *Reichskammergericht* to exercise appellate jurisdiction there.

The Villmergen Wars and Louis XIV.—The soil of Switzerland, however carefully cultivated, could not support its growing population, and the temporary prosperity caused by the wars gave way to a depression in the latter part of the 17th century. Exports were necessary, and for this an industry was required which should use as little heat as possible and make the maximum use of human ingenuity and activity. Home industries were popular, partly because conditions in the valleys restricted outdoor work, particularly in the winter. Hence wood carving, spinning, frame-work knitting and embroidery were popular; water power made textile manufacture (silk, cotton and linen) profitable, particularly around the lake of Zürich and in St. Gallen; and in western Switzerland the construction of clocks and watches and of musical instruments, at first luxury trades allied to the art of the goldsmith and the jeweller, centred in Geneva, spread to Neuchâtel, Olten, La Chaux-de-Fonds and Le Locle. Basle was a commercial city, where stockings and silk ribbon and the preparation of tobacco and snuff occupied many; Berne remained primarily the capital of a great agricultural state, where the real or imaginary virtues of the peasant received an exaggerated recognition which was later to become a kind of intellectual cult (popularized by Hans Caspar Hirzel in his *Wirthschaft eines philosophischen Bauers*, 1761). Mercenary service, particularly with the French army, was a popular form of employment, and returning soldiers brought news of foreign markets and fashions that was often valuable.

The government of a number of states, Berne, Lucerne, Fribourg and Solothurn in particular, was in the hands of a patrician aristocracy, exclusive and splendid. Difficult economic conditions after the Thirty Years' War led to a rising in 1653 of the peasants of the Entlebuch against Lucerne. With the help of neighbouring governments it was suppressed, but it was followed by similar trouble in the Bernese Oberland and in the rural territories of Basle. The peasants seemed united, and the cities in alarm cooperated for the defense of their privileges, irrespective of religious differences. A battle at Herzogenbuchsee established their superiority, and harsh punishments were meted out (followed by some belated reforms). Zürich tried to make the confederation more of a reality, but the attempt broke on the rock of religious prejudice. The Catholic states reinstituted the Golden league in 1655, and the expulsion of some Protestant families from Arth led to a split between Schwyz and Zürich which developed into civil war between the five inner states and Zürich allied with Berne. At Villmergen (Jan. 24, 1656) the Catholics under Christopher Pfyffer defeated their opponents and reasserted to the full the favourable position secured at Kappel and the complete individual sovereignty of the cantons.

In the age of Louis XIV the Swiss could hardly escape the all-pervading influence of Versailles. If the Protestant states were not very eager to help the persecutor of the Huguenots, and the Catholic states looked to Spain for help, both could be influenced by the appeal of Jean de La Barde, the French ambassador, to renew the Perpetual understanding with France. In 1663 an embassy confirmed this renewal by a spectacular public oath in Notre Dame at Paris and for the next half-century French influence was paramount in such external relations as the confederation had. Louis XIV's aggressive policy was in many respects at the expense of ancient Swiss interests. At the end of the 15th century Swiss influence had been almost paramount in the Franche-Comté and in Alsace, and these were exactly the areas against which Louis proceeded most successfully. In 1667–68 the Habsburgs succeeded in retaining possession of the Franche-Comté, but the French threat to it alarmed the confederates. Its final annexation to France in 1678 brought France to the Bernese frontier and caused fears for the future of the French-speaking Vaud, while the French occupation of Strasbourg meant that Mulhouse and Rottweil could not hope to remain permanently linked with the confederation. Basle, too, recognized how serious French pressure could be when a French battery at Hüningen confronted its defenses. The confederation remained discreetly neutral during the War of the Spanish Succession, but politically its independence was the safer because of the victories of the duke of Marlborough and Prince Eugene. One other setback to France occurred in Neuchâtel: on the extinction of the ruling French family of Orléans-Longueville in 1707, a struggle ensued between the French candidate François Louis de Bourbon, prince of Conti, and the Prussian king Frederick I, in which the latter won the principality for the Hohenzollerns.

The religious question in the common lordships, particularly the Thurgau and the Rheintal, was a delicate one, as the populations of both creeds were ruled by nominally co-operating states of similarly divergent faiths. Questions of mixed marriages and the education of children were urgent ones and roused strong feelings, which were accentuated by the attempt of the prince-abbot of St. Gallen to dictate to his mainly Protestant subjects in the Toggenburg district. A road entirely under Catholic control was being constructed from Schwyz into imperial territory, and the abbot Leodegar Bürgisser was determined that the Toggenburgers should contribute labour and materials to its construction. They demurred and appealed successfully for support to Berne and to Zürich, and in 1712 an armed conflict broke out. The abbot had the support of the emperor Charles VI, which made France willing to mediate; moreover, the French representative, Charles François de Vintimille, comte du Luc, was well-disposed to the Protestant cause. Berne and Zürich co-operated well, while Lucerne was unable to co-ordinate effectively the forces of the Forest cantons. The abbot fled, the Protestants won a victory at Bremgarten, besieged Baden and blockaded their enemies elsewhere. A final battle (July 25, 1712) at Villmergen settled the issue in their favour; and the peace of Aarau (Aug. 11, 1712) established real equality of treatment for both sides in the common lordships, increased decisively the influence of Berne and Zürich in the confederation and entirely superseded the second peace of Kappel.

The Eighteenth Century.—Every form of government existed side by side: a patrician aristocracy, proud, exclusive and competent, ruled in Berne, Fribourg, Lucerne and Solothurn; Zürich, Basle and Schaffhausen were governed by their craft guilds and trading corporations; in the oldest states, Zug, Uri, Unterwalden, Schwyz, Glarus and Appenzell, the primitive democracy of the *Landesgemeinde* assured the participation in the government of every adult male citizen; in Neuchâtel and St. Gallen autocratic princes were in power. Every state, individually or collectively, ruled subject territories; there was little sense of nationality and no common language, coinage, system of weights and measures,

army or law courts. There was a general air of contentment, prosperity and industry and determination not to change. A vigorous and varied intellectual life was evidenced by the work of Johann Jakob Bodmer, Johann Caspar Lavater, the Bernouilli family at Basle, Albrecht von Haller and Johann Heinrich Pestalozzi (*qq.v.*), as well as the philosopher Isaac Iselin (1728–82). The country was increasingly visited by foreigners: Edward Gibbon wrote much of the *History of the Decline and Fall of the Roman Empire* in Lausanne; Voltaire was to be found on the frontier at Ferney. Jean Jacques Rousseau was proud to describe himself as a citizen of Geneva, and his thought was profoundly influenced by Swiss conditions. The general complacency was disturbed by several manifestations of discontent. John Daniel Davel attempted to free Lausanne and part of the Vaud from the domination of Berne in 1723; he was quite unsuccessful and was executed, but not forgotten. There was trouble in Appenzell raised by Lorenz Zellweger in 1733. Geneva unwillingly acquiesced in a greater degree of democratic government in 1738. A serious conspiracy against Berne headed by Samuel Henzi was decisively dealt with in 1749. There were demonstrations against the authority of Uri in the Val Leventina in 1755 and armed opposition to the patricians of Fribourg, led by Nicolas Chenaux, in 1781; but neither these, nor somewhat similar explosions in Schwyz, Lucerne and Geneva, presented any real challenge to constituted authority. All the time a consciousness that something more than mere defense and self-interest held the Swiss states together was growing, and this found public expression in the formation of the Swiss society (*Helvetische Gesellschaft*) in 1761.

The French Revolution and Napoleon.—The ideas of "enlightenment," rationalism and general improvement which became widespread in 18th-century Europe were eagerly absorbed in Switzerland. The writings of Montesquieu, Voltaire, Denis Diderot, Jean Le Rond d'Alembert and the Encyclopédistes, as well as the almost home-bred solvent thought of Rousseau, powerfully influenced the intellectual circles; many talked of liberty and equality in societies in which there was little practical application of either. Some of the more advanced thinkers had found life more congenial in France than at home in 1789, and in 1790 a "club of Swiss patriots" was founded in Paris by Jean Castellaz and supported by a number of Vaudois refugees, by Henri Monod, by Jean Jacques Cart and, most notably, by Frédéric César La Harpe who had been employed by Catherine the Great in Russia to teach her grandson Alexander. In 1791 F. C. La Harpe was urging the French people to support the malcontents in the Vaud and the Valais while, as in Great Britain, the conservatives in Switzerland were in strong opposition to Jacobinism. Feeling was roused to violent heights by the massacre of the Swiss guards of Louis XVI in the Tuileries (Aug. 6, 1792); but neither this event nor the invasion of the lands of the bishop of Basle by a French army nor even the formation of the First Coalition led to war. In Paris Robespierre urged correctly that the interests of France called for a friendship with the Swiss people; and the war party in Switzerland, led by Niklaus von Steiger, was able to secure only an agreement that the allies might recruit Swiss mercenaries. There was, however, a good deal of anti-French activity in Switzerland, including the collection of war material for use against France and a spy service in the pay of William Pitt's representative, Sir William Wickham.

The successful invasion of Italy by Napoleon Bonaparte in 1796 and the peace of Campo Formio (1797) was soon followed by the annexation to the Cisalpine Republic of the three provinces ruled by the Grisons, the Valtellina, Chiavenna and Bormio, and the Swiss could do nothing but accept the accomplished fact. In Paris, La Harpe and Peter Ochs of Basle were urging a French invasion of Switzerland in the name of liberty, using the separatist movement in the Vaud as an excuse for intervention. There were inspired riots in the Liestal near Basle and elsewhere, culminating in the proclamation of a "Republique Lémanique" in Jan. 1798. The French Directory at once sent soldiers to the help of the insurgents: Berne resisted, but received no help from the diet of the confederation, which debated fruitlessly at Aarau. A French contingent was driven back at Neuenegg (March 5) but at the same time the main Bernese force capitulated at Grauholz and the city of Berne was occupied. Great quantities of supplies and bullion were carried off to France by Bonaparte's agent Guillaume Brune, while Peter Ochs drafted a new constitution for a unitary Helvetian republic. The common lordships and the associated districts were abolished; the number of cantons was enlarged from 13 to 23; a bicameral legislature (great council and senate), chosen indirectly by manhood suffrage, was to be responsible for law-making; and a directory of five members was constituted the executive. The rights of the individual citizen were written into the constitution, including freedom of worship, of meeting, of petition and of the press. A national militia was embodied, and local government was controlled by centrally appointed prefects.

The new constitution was not imposed without resistance. In Nidwalden a revolt was savagely put down by Gen. Balthasar de Schauenbourg, but discontent continued to manifest itself in the east, especially when the country was marched over by opposing armies. A compulsory alliance with France gave that country the right to use Swiss roads for military purposes, and the French guarantee of the Helvetian republic offered easy opportunities for intervention. The allies regarded the republic as a satellite of France, and in May 1799 Austrian and Russian forces under Suvorov met a French army under André Masséna near Zürich before making a classic retirement into the Vorarlberg. The campaign had devastated the countryside; the price of provisions rose alarmingly; and a bad harvest made the winter of 1800 one that was long to be remembered for misery and unemployment. The cost of the new centralized government was relatively high, although the burden was more equally distributed, direct taxation being introduced for the first time and feudal dues, corvées, tithes and ground rents abolished without compensation. Some money was spent on education, and an elaborate scheme of free or cheap public instruction (culminating in a national university as in France) was adumbrated, but little could be done in a short time. J. H. Pestalozzi, however, was given a free hand to proceed with his innovations, which attracted much notice, although his adventures in journalism, as editor of the *Helvetisches Volksblatt*, were less satisfactory. The first constitution barely outlived the Directory in France. Then, after violent struggles between the protagonists of greater centralization and those who stood for more cantonal authority, the Malmaison constitution was established in May 1801, and Aloys Reding was chosen as the first *Landammann* or head of the state of 15 cantons. He had to meet political and financial difficulties, culminating in a rebellion in the Vaud and a kind of counter-revolutionary movement in Aargau and Berne.

Napoleon promptly intervened to dictate the Act of Mediation from Saint-Cloud (Sept. 30, 1802; amplified on Feb. 19, 1803). The cantons were again defined with boundaries substantially as they have remained ever since. Berne lost most, Aargau and Vaud becoming separate entities at its expense; the Grisons became part of the confederation, with Ticino, St. Gallen and Thurgau. There were now 19 cantons: the new ones, where representative democratic institutions were accepted; the old *Landesgemeinde* cantons, where popular open-air voting continued but was limited to men of 20 years or more; and the city cantons Zürich, Berne, Fribourg, Solothurn, Basle and Schaffhausen, where the old aristocracy regained some of its ancient influence under new forms. With Lucerne substituted for Schaffhausen, these latter became the directing cantons, having seniority in turn, the chief magistrate for the year having custody of the seal of the republic and presiding over the assembly. The sovereign rights of the cantons, the issue of money, control over customs, education, monasteries and the posts, were restored, but freedom before the law, of settlement and of occupation was guaranteed to all citizens.

Napoleon was at first a relatively popular protector until the war with England obliged him to demand the 16,000 men promised him by the military capitulation. British recruiting of mercenaries was stopped and Switzerland forced to participate in the continental system with very great harm to its own commerce and industry, particularly in cotton. The Swiss frontiers were violated by armed forces. Thousands of Swiss took part in the Russian campaign, distinguishing themselves in the crossing of the Beresina

during the retreat but losing most of the effectives. The Valais, which had remained aloof from the Swiss republic was united with France as the *département* of the Simplon in 1810, nominally to put an end to anarchy; Ticino was occupied by French-commanded Italian troops in order to stop smuggling; and Neuchâtel was handed over to Marshal P. A. Berthier as a kind of feudal fief. When therefore it became apparent in 1813 that the Napoleonic empire was crumbling after the battle of Leipzig, the *Landammann* for the year, Hans Reinhard, called a special assembly at Zürich which voted for a policy of armed neutrality. Prince Metternich soon saw this to be on the whole to the advantage of France and encouraged certain discontented elements, who desired a restoration of prerevolutionary conditions, to apply for military help. A force marched through northern Switzerland on its way into France at the beginning of 1814, while the Napoleonic Act of Mediation was formally denounced.

The Restoration.—The congress of Vienna devoted comparatively little time to the Swiss question, but certain of its decisions were none the less of far-reaching importance. Swiss affairs were left largely to the competent advice of Baron Heinrich vom Stein, Baron Wilhelm von Humboldt, Count Capo d'Istria and Stratford Canning, who made as few boundary alterations as possible. The most serious loss was to Austria, which annexed from the Grisons the three districts of Chiavenna, Bormio and the Valtellina. On the other hand, partly as a result of the efforts of Charles Pictet de Rochemont, Geneva was at last united to the confederation with reasonable boundaries, as too was Valais. Neuchâtel, part of the dominions of the king of Prussia, also came in, and the independent existence of the Vaud as a separate canton was accepted. Berne received the city of Biel and the former prince-bishopric of Basle. The northern part of Savoy, on the southern shore of the lake of Geneva, was declared neutral, as was, permanently, the whole Swiss state. This declaration and a guarantee of Swiss integrity was reinforced by the second peace of Paris (Nov. 20, 1815). The return of Napoleon from Elba made no substantial difference; Swiss soldiers in the service of France did not join him, a Swiss contingent marched with the allies, who were allowed to cross Swiss territory, into Upper Burgundy. There was a small modification of the frontier of the Vaud and the creation of a free zone in Gex and its neighbourhood under the treaty of Turin (March 16, 1816). Mulhouse remained in French hands and the Swiss confederation now consisted of 22 contiguous cantons. Its constitution, after a conservative patrician restoration in Berne and some rioting elsewhere, had been settled at the "Long diet" of Zürich in 1814. Its keynote was the full restoration of the sovereignty of the cantons, almost the only federal institution being the army, for the defense of the frontiers, and for the upkeep of which a special fund was voted. Each canton was equally represented in the diet, Lucerne, Zürich and Berne acting as chief city for two years in turn. The possessions of the monasteries were placed under federal protection, but the earlier general freedom of worship, as of settlement and occupation, were not retained. Each canton continued to collect its own customs, coin its own money and manage its own affairs by the customary machinery. The franchise was everywhere limited so as to favour the old ruling families and the property owners, and any alteration of the federal *status quo* was made constitutionally impossible.

Military service with foreign powers again became possible, Louis XVIII gladly enlisting a number of men. Reserving its neutrality, the confederation declared its adhesion to the Holy alliance in 1817, thereby pleasing the tsar. Refugees in some numbers (including the future Napoleon III) obtained asylum within its borders, so that Metternich complained that the country was a focus of revolutionary plots and in a state of anarchy. The diet even agreed to place limitations on the freedom of the press and on the reception of aliens. Economically the country suffered from the rigid tariff restrictions of its neighbours, France and Austria in particular, from the decline in European purchasing power after the Napoleonic wars, from successful British competition in world textile markets and from its own constitutional inability to have any common policy on imports. Apart from some slight manifestations of embryonic nationalism and some rather more substantial signs of a religious revival, the Swiss states showed little activity in the 1820s.

News of the July revolution in Paris in 1830 caused a good deal of excitement among the politically minded young men of certain Swiss cities. Clubs, societies, even athletic associations began to demand larger measures of cantonal democracy, more popular education and some protection of women and children against industrial exploitation. A number of mass demonstrations led to the introduction of more liberal legislation in 11 of the larger cantons in 1831, implying the acceptance of the principle of popular sovereignty and the expansion of the franchise. More schools and training colleges for teachers were opened and universities were founded at Zürich and Berne. There were, however, exceptions and the surge forward was followed by a reaction. In Schwyz the opposition of reformers and conservatives was so violent that only the intervention of federal troops saved the state from civil war or self-partition. In Basle long-standing differences between the relatively wealthy city, with great external interests, and the predominantly agricultural countryside came to a head in 1831. The adoption of a democratic constitution for the state would give political preponderance to the country people and this the citizens were determined to resist. After violent demonstrations in 1831 the canton was divided in 1833 into two halves, Basel-Stadt and Basel-Land, which have remained permanent. Frederick William III of Prussia in 1831 most reluctantly abandoned a small part of his absolute rights in his principality of Neuchâtel (*e.g.*, that of nominating the whole of the cantonal council); but there were clashes between the republicans and the monarchists, neither of which was long satisfied with the compromise agreed to by the monarch. One result of these differences was the formation in 1832 of the Siebnerkonkordat (Zürich, Berne, Lucerne, Solothurn, St. Gallen, Aargau and Thurgau) opposed by the conservatives united in the Sarnenbund (Basel-Stadt, Uri, Unterwalden, Schwyz and Neuchâtel). None of these internal changes affected the traditional willingness of the country to shelter political refugees: Poles were welcomed in considerable numbers in the north, while the harbouring of Prince Louis Napoleon (particularly after his attempted coup at Strasbourg) and the notorious use of Swiss bases by Giuseppe Mazzini almost brought about war.

The Sonderbund War.—The 1830s were years of considerable literary activity and of much thought about the future of the confederation. Strictly constitutional revision was difficult, if not impossible, but the changing needs of the times and the general modification of opinion toward more liberal forms of government clearly suggested change. With a growth of national feeling went a growing conviction that there were certain minimum individual rights of the citizens that ought to be secured to all, and some were prepared to enforce this point of view; others were impressed by the expense and dislocation caused by each canton's having its own tariff and customs barriers. There were several local manifestations of discontent but they remained localized and ineffective. The bond of union was found in religion. How was the principle of religious freedom to be enforced? The Articles of Baden (1834), condemned by Pope Gregory XVI but upheld by the liberal cantons, called for a general diminution of ecclesiastical privileges and exclusive claims; the mass demonstration against the appointment of D. F. Strauss to a chair of theology at Zürich in 1839 indicated the depth of passion aroused. Matters came to a head in Aargau. There in 1835 the monks of Muri had objected to taking an oath of loyalty, and in 1841 the Catholic minority demonstrated in arms against a liberal revision of the constitution. The government then dissolved the Aargau monasteries, which were held to have fomented the revolt. The federal pact of 1815, however, had expressly guaranteed the property of the monasteries against secularization, and the Aargau Catholics appealed to their friends in the south. The chief Catholic canton was Lucerne, and there Joseph Leu had taken advantage of the situation to secure the recall of the Jesuits, invited by Eutych Kopp, to undertake the teaching of theology and the control of the clerical seminary. This action was lawfully done and lay within the proper province of the canton, but was highly provocative. A demonstration against it in Lucerne itself was severely punished, and a general popular de-

mand for the expulsion of the Jesuits from the confederation was ignored. The Radicals passed from argument to violence, Joseph Leu was found shot, and from most of the Protestant cantons bands of volunteers (*Freischärler*) marched on Lucerne under the command of Ulrich Ochsenbein, a Bernese staff officer. The expedition was mismanaged, and in a fight at Malters more than 100 men were killed and more than 1,800 made prisoner (April 1, 1845).

The battle was followed by the union of the Catholic cantons, Lucerne, Uri, Schwyz, Unterwalden, Fribourg and Valais into a separatist confederation, the Sonderbund. The primary purpose was to prevent any alteration of the weak federal act of 1815, even if this were the declared will of the majority of the people, and foreign alliances were welcomed to this end. Through 1846 opposition grew. Berne, Solothurn, Zürich, Vaud and finally Geneva (under James Fazy) elected radical governments, determined to declare the Sonderbund an unlawful pact. In May 1847 St. Gallen joined the liberal cantons, and 12 votes out of 22 were certain. The diet met in Berne in July 1847 under the presidency of Ochsenbein and by a majority declared the Sonderbund to be dissolved. A commission was appointed to draft a new federal pact, and the expulsion of the Jesuits from Lucerne, Fribourg, Schwyz and Valais was ordered, together with their exclusion from the whole confederation. In the name of religion and of state rights the minority determined to resist by force. Their leader, Constantin Siegwart-Müller, purchased arms, collected an army under the command of Johann Ulrich von Salis-Soglio and looked for support from Louis Philippe and Metternich. This, partly because Lord Palmerston openly sympathized with the opposite side, was slow in coming. The Sonderbund War was soon over. While at Lucerne there were divided counsels and uncertainty of purpose, the Radical cantons entrusted their men and fortunes unreservedly to Guillaume Henri Dufour of Geneva, a somewhat conservative professional soldier, simple, upright and unselfish. Dufour had more men than his opponents, and these better trained and equipped, with better guns and superior economic advantages. All these he used to decisive effect. Fribourg capitulated on Nov. 14, 1847, almost without fighting, and the ring closed relentlessly in on Lucerne. Zug surrendered on Nov. 21, and two days later the decisive battles were fought at Meierskappel and Gislikon. Lucerne was entered, officers, Jesuits and nuns fleeing by steamer to Fluelen and then over the St. Gotthard to exile. Valais was the last canton to submit, on Nov. 28. Somewhat more than 100 men on both sides had been killed. The costs of the war were charged to the losers, and Appenzell Inner Rhoden and Neuchâtel had to pay fines for their neutrality. A collective note from the powers, unsupported by Palmerston (who sent Stratford Canning with sympathetic instructions to Berne), could be and was ignored until the greater troubles of 1848 left Switzerland free to work out its own destiny.

The New Federal State, From 1848.—The revision commission had a new constitution ready for submission to the cantons in June 1848, and it was adopted with little change by 15½ cantons (1,897,887 votes) against 6½ (293,371 votes). The central authority of the confederation was strengthened, particularly in regard to defense, law and order and the promotion of the common welfare. There was to be a cabinet or executive (*Bundesrat*) of seven, a supreme federal court (*Bundesgericht*), a senate or council of states (*Ständerat*) consisting of two representatives from each canton and a national council (*Nationalrat*) representing the county as a whole. Foreign affairs became the concern of the federation only, although separate cantons might, with federal approval, make agreements not of a political nature with one another and with neighbouring countries. The posts, currency, weights and measures and customs duties became the province of the federation, which thus acquired an independent revenue, cantonal expenses being met by local levies, taxes on salt, an excise on wine and stamp duties. Universal military service in a federal force was accepted; very small cantonal armies were approved, and the cantons controlled infantry training but not the cavalry or artillery. Service with foreign armies, military capitulations and the acceptance of foreign pensions or decorations were prohibited. Freedom of the press, of worship, of association and of settlement and equality before the law were secured to all, but these were somewhat narrowly interpreted in some cantons—the Jews remained under special disabilities and the Jesuits were excluded. Berne became the seat of the government, Lausanne of the high court and Zürich of the federal institute of technology. It had been the hope of many that a great federal university at Zürich would unite the higher education of the country, the ordinary teaching of children being left to the cantons; but the existing academies at Geneva, Lausanne and Neuchâtel and the universities of Berne and Basle were not prepared to accept this measure of academic unification, and in the end only technology was thus centralized. Similarly it was only after considerable differences of opinion that the French franc and the metric system of weights and measures were fully adopted.

Foreign Affairs.—Neuchâtel, part of the dominions of Frederick William IV of Prussia, had in 1848 adopted a republican form of constitution, which had been accepted as that of a federal canton. This was partly the work of the industrial region of Le Locle and La Chaux-de-Fonds and was resisted by the older ruling families, who proclaimed their loyalty to their monarch. The last of several attempts at counterrevolution took place in Sept. 1856, when the loyalists under Comte Frédéric de Pourtalès-Steiger gained possession of the castle of Neuchâtel and had to be ejected by force. The king of Prussia threatened to intervene on behalf of his "subjects" and mobilized his men; the federal army was placed on a war footing and sent to the northern frontier. British good offices and diplomatic pressure on Prussia by Lord Palmerston were followed by the mediation of Napoleon III, and in 1857 the king gave way, renounced all sovereign rights and secured an amnesty for his supporters.

More serious was the question of refugees. Switzerland, like Great Britain, was a home for political exiles from many countries, and Giuseppe Garibaldi and Mazzini now found safety from the Austrian police there. Mazzini continued to plot the violent overthrow of the lawful rulers of Lombardy and Venetia and attempted to gain recruits for his secret associations until he left the country. In 1850 some measures were taken to prevent Switzerland from becoming too obvious a base for revolutionary propaganda but the law on this subject was never very strictly enforced. In the Ticino the sympathy of the population for Italian nationalism combined with provocative anticlerical actions led to Austrian reprisals in the form of the expulsion of Ticinese from Lombardy and of an economic boycott which caused much suffering. Perhaps only Austrian preoccupation elsewhere prevented matters from being pushed to extremities. During the war of 1859 federal troops prevented Swiss sympathizers from crossing the frontier to join the insurgents and secured the internment of belligerents who fled north. The war was followed in 1860 by the cession of Nice and Savoy to France and the reopening of the question of the neutral zone of Chablais, Faucigny and the Genevois. A federal councillor, Jacob Stämpfli, threatened to readjust matters by a Swiss occupation of this area, a threat impossible to carry into effect as the easy repulse of a Genevan force that attacked Thonon in March 1860 clearly showed. In the end the neutral zone was enlarged a little, arrangements made about the collection of customs and the issue shelved until 1919 (when full French sovereignty over the area was to be asserted and accepted). The war had further been responsible, indirectly, for the establishment of the International Red Cross organization, a widely read pamphlet by Henri Dunant having drawn attention to the unnecessary sufferings of the wounded at the battle of Solferino (1859). In 1864, after much local activity, the Convention of Geneva regulated the care of wounded in war and arranged for the neutralization of the medical and ambulance services, distinguished by the federal cross in reverse colour.

Economic Development.—The Swiss people did not at first welcome the advent of the railway: it was believed to be aesthetically and technically unsuited to mountainous country and it threatened the prosperity of the roadside hotels. The interests of Basle and Zürich conflicted and cantonal state-rights were a serious obstacle. It was therefore not until 1847 that an experimental line

was opened between Baden and Zürich. After a report from Robert Stephenson the federal council accepted the necessity for planned railway construction, and a conflict between Alfred Escher on the side of private enterprise and Jacob Stämpfli on that of state ownership and control resulted in the victory of the former. There was soon a mania for railway speculation, and lines were built with little or no co-ordination, sometimes in conscious rivalry. In 1853 the North Eastern railway linked Zürich with the Rnine and the lake of Constance, and in the same year the route Morges-Lausanne-Yverdon was opened; by 1859 the Central railway joined Basle with Olten and thus to Lucerne on the east and to Solothurn, Berne and Thun on the south. Finance, politics, personalities, cantonal rivalries and strategic considerations soon caused difficulties. The construction of a railway through the St. Gotthard tunnel was not completed until 1882, after much negotiating with Baden and Württemberg and with the Italian government. Escher was chairman of the company responsible, the confederation refusing to accept any financial obligations. The estimates proved inaccurate, and Escher was forced to resign, some part of the excess cost being borne by public funds. There were difficulties about gauge, locomotives and differential rates, and in 1883 a suggestion of unification by public ownership was rejected by a small majority. A similar suggestion was rejected by a referendum in 1891; but in 1898 nationalization of the main lines was accepted by a popular vote, and the principle was extended in 1903 and 1909.

The existence of ample water power and an industrious population gave Swiss industry a good start, but the absence of coal made further developments difficult until the progress of hydroelectric schemes supplied an alternative source of heat and energy. Swiss textile manufactures, including cotton goods, largely held their own in a predominantly free-trade world but declined in face of growing protection and large-scale competition. Embrodiery of good quality, however, was to maintain a wide market until about 1920, as did the Basle silk-ribbon industry. Dyeing led to a considerable development of the chemical industry; and the traditional localized watchmaking and clockmaking was supplemented by large-scale factory production, which met with considerable success and led to the making of a wide range of machines and locomotives. The home production of grain decreased in the 1880s, when it became much cheaper to import foreign wheat; the farmers turned to stock breeding and dairy farming. Cheese making, the export of milk products of all kinds and the chocolate industry became widespread. Better communications with the outside heightened the flow of the valued tourist traffic.

Constitutional Revision and Internal Politics, 1860–1914.—The German *Kulturkampf* had its repercussions in Switzerland. The issue of the *Syllabus errorum* by Pius IX in 1864 attracted a good deal of attention and helped to make the Radicals also to some degree anticlerical, and the definition of papal infallibility in 1870 and the emergence of the Old Catholics in Germany, with many sympathizers in Switzerland, created difficulties. The Catholics of the diocese of Basle, in particular, refused to follow their bishop, Eugène Lachat, in accepting papal infallibility and declared him deposed. In this they were upheld by the cantonal governments, particularly Berne, but a majority of the clergy stood by their bishop, refused to accept his removal and protested against the secularization of his property. Berne now required that parish priests should be chosen by their parishioners from among those who were approved by the government and had undergone a state examination. In Geneva the action of the pope in appointing Gaspard Mermillod to an apostolic vicariate there without any prior consultations led to Mermillod's being expelled from Switzerland (1873), to the recall of the papal nuncio and to the prohibition of the activities of religious associations in schools.

The feeling thus aroused helped forward the growing demand for a general revision of the constitution of 1848. The introduction of the "initiative" (*i.e.*, the right of the people to propose legislation) into the canton of Zürich in 1865 was a victory of the left-wing democrats over Escher and his followers. The freedom of the press was extended, the principle of payments to councillors was accepted, and the example of Zürich was largely copied by Berne, Lucerne and Solothurn. In 1866 the Jews, who had been denied freedom of settlement on commercial grounds, were admitted to full civic rights. In 1874, partly as a result of the Franco-German War, a revision of the conditions of military service was generally demanded. The division between those demanding greater centralization and increased federal authority and those upholding the rights of the cantons was focused on the rivalry of Emil Welti of Aargau and Louis Ruchonnet of the Vaud. The Radicals were only partially successful, but a revised federal constitution was accepted by popular vote in 1874. Direct popular control over the government was further extended by the principle of the referendum, by which a national verdict on an issue could be sought if properly demanded by 30,000 votes or eight cantons. In 1891 it was agreed that a demand by 50,000 votes (the initiative) could bring similar machinery directly into operation. The army was more directly centralized: discipline and military education, the provision of arms and the collection of exemption-payments were to be federal matters, the force being based on the cantons (which also promoted some of the officers). Freedom of trade and choice of occupation within any canton was secured to all, and each canton was obliged to make provision for full primary education. Teaching was to be secular, civil marriages were made compulsory and the foundation of new monasteries was forbidden. Certain other anticlerical regulations were made. The authority and appellate jurisdiction of the federal court at Lausanne was upheld and extended, and federal laws dealing with factories, bank notes and the railways were made more comprehensive. The money needed to meet the additional expenditure was secured by the extension and raising of duties on imports.

The opening of the St. Gotthard route attracted some attention to the Ticino; an increasing number of immigrants heightened party rivalries, Radicals and Conservatives being almost precisely equally balanced. Religious feeling made matters worse; the Conservatives were accused of manipulating the elections so that they would remain permanently in power; and rioting in 1890 ended in the formation of a provisional government. Armed federal intervention became necessary, a revised electoral law introduced proportional representation, and an increased electorate was followed by a Radical and peaceable administration. Growing industrialization and an increase in the size of the urban populations were accompanied by the spread of socialism. The Social Democratic party formed in 1870 avowedly existed to forward the claims of the manual workers and, under Otto Lang, began to demand social reforms and positive opposition to large-scale capitalist enterprise. A notable piece of practical socialism was the slow nationalization of the railways. Some action was necessary to prevent important sections of the railways from passing under foreign control, and in 1891 the federal council negotiated the purchase of the Central railway; but the proposal was negated by a popular referendum. Seven years of discussion followed, accompanied by an occasional strike. Then in 1898 agreement was secured for the public purchase of certain main lines. The principle was extended in 1903 and 1909 and was to make much easier the later electrification of the federal lines.

Political refugees, their numbers increased by German anti-socialist legislation, continued to be a source of difficulty. In 1889 a German police inspector, August Wohlgemuth, arrested as a spy, was expelled from the country only after an acrid exchange of notes between the Swiss government, represented by Numa Droz, and Bismarck. Anarchists were more difficult to control or eliminate. In 1898 the Austrian empress Elizabeth was assassinated in Geneva; and in 1902, after the murder of King Humbert of Italy, the Italian government demanded that action should be taken against Giulio Silvistrelli for provocative newspaper articles. A temporary breaking-off of diplomatic relations between Switzerland and Italy followed, but normal intercourse was soon restored. The principle of permanent neutrality had become firmly accepted by the people when World War I began in Aug. 1914.

World War I.—Attention in 1914 in Berne was soon transferred from the Swiss national exhibition to the needs of defense. The wisdom and the value of the policy of neutrality, imposed

alike by public instruments, by national interest and by tradition, was never in doubt. The citizen-army was rapidly mobilized and sent to guard the frontiers. There was a momentary controversy over the choice of a supreme commander, the parliamentary representatives voting for Theophil Sprecher von Bernegg, the federal council (supported by a decisive popular vote) choosing Ulrich Wille. Fortunately a neutral Switzerland had certain advantages both for France and for Germany, and no attack upon its frontiers was ever seriously considered. Universal military service, the rigours of campaign conditions without an enemy to fight and the use of soldiers for public works were less resented than the economic conditions imposed on a country which could neither entirely feed itself nor supply all its own raw materials. The tourist traffic, which the 20th-century enthusiasm for mountaineering and allied pursuits had rendered especially active, came to an end; a run on the banks was with difficulty averted; and the large number of resident foreigners added certain difficulties. But it was soon apparent that Swiss services could be of value alike to both belligerent groups and a certain amount of trade became possible. For certain purposes Cette became an open port for Switzerland. Heavy taxation and a good deal of borrowing were necessary; there was a violent controversy when two officers, Col. K. Egli and Col. M. von Wattenwyl, were discovered to have given military information to the Germans (Feb. 1916); sympathy with the Allied war aims was most prominently expressed by the French-speaking Swiss. The factory workers in the cities were discontented at the rapidly rising prices and at political and industrial conditions unfavourable to them; and the Social Democratic party became a vehicle for the teaching of Lenin, resident in Zürich until his transference to Russia by the Germans. The constitution, however, made political action slow and ineffective, and in Nov. 1918 a general strike was called. The workers demanded a 48-hr. week, old-age pensions, national health insurance, female suffrage, the election of a new national council by proportional representation, conscription of labour and a capital levy. Prompt action by the administration, the hurried expulsion of the Soviet legation, the arrest of strike leaders and the use of some show of military force ended the general strike quickly, after which a number of the demanded reforms were enacted. Concurrently with the general strike the serious influenza epidemic that affected so much of Europe wrought considerable havoc.

Swiss agencies, governmental and private, including the Red Cross, were much used by the belligerents, but the expression of Swiss opinion had little effect on the course of the war or on the peace negotiations in Paris. The collapse and partition of the Habsburg empire decisively altered conditions on the Swiss eastern frontier, where the inhabitants of the Vorarlberg wished to form themselves into a new canton of the confederation. The decision about this rested with the Allies, who declined to detach the territory in question from the new Austrian state and ignored the principle of self-determination, so that the treaty of Saint-Germain-en-Laye left the frontier there unchanged. Switzerland was affected in several ways by the treaty of Versailles: the international control of shipping on the Rhine thereby became very much a concern of France; the agreement with Germany about the regulation of the St. Gotthard line was revised; and the neutralized "free" zone of Gex and Upper Savoy became an undifferentiated part of the French republic.

The League of Nations.—The Covenant of the League of Nations, in spite of the flattering choice of Geneva as the headquarters of the organization, was not regarded with satisfaction in Switzerland. The guarantees for the maintenance of peace in Europe were less adequate than the Swiss project had suggested, and it was obviously difficult for a permanently neutral state to be associated with the enforcement of collective security and with active resistance to aggression. But Swiss idealism welcomed the general implications of the League, and outstanding difficulties were solved when, by the Declaration of London (Feb. 13, 1920), the council of the League recognized the special position of Switzerland as permanently neutral and agreed that no military assistance, direct or indirect, could be required from it in the event of a breach of the covenant, although "economic sanctions" would become applicable. The issue was long debated; the federal council advised entry into the League, which was accepted by the *Nationalrat* by 115 votes to 50, by the *Ständerat* by 30 to 6. The necessary referendum on May 16, 1920, revealed even greater caution: 11½ states were for, 10½ against, and the final figures revealed a favourable majority of 90,000 in a total vote of 700,000. On the social, economic, intellectual, industrial and medical committees of the League of Nations Swiss help was prominent. The country readily accepted the Kellogg pact abolishing war as an instrument of policy, and it advocated the early admission of Germany into the League. The passage of foreign armed forces across Switzerland, even on the most direct and manifest League missions, was strenuously and successfully resisted. Relations with the U.S.S.R., embittered by the murder of the Soviet representative V. V. Vorovsky at Lausanne in 1923, remained unsatisfactory, and Switzerland opposed the admission of that country into the League in 1934. In 1935 trade relations with Italy were not broken off when Italian forces invaded Abyssinia, although an embargo was placed on the export of arms to both sides. The Sino-Japanese War, the failure of the Disarmament conference, the war in Spain and the successful *Anschluss* between Germany and Austria caused a national reaction, and in May 1938 Switzerland publicly refused to participate in future sanctions.

World War II and After.—Switzerland had foreseen the outbreak of a general conflict and was militarily prepared for World War II. On Aug. 30, 1939, Henri Guisan was elected general (commander in chief) by a large majority. The army was mobilized, the frontiers guarded and conscription of labour enacted. The tourist traffic and with it the hotel industry, already affected by European conditions, suffered greatly, and both imports and exports were exposed to severe and immediate limitations. There are many expensive diplomatic and Red Cross activities, and with the fall of France in 1940 a large number of French and Polish troops crossed the frontier and were interned. Belligerent aeroplanes flew high over Swiss territory and were seldom shot down; certain towns, notably Schaffhausen, were accidentally bombed. Defense measures were deliberately concentrated upon the mountainous interior, and these were not put to the test. War materials were supplied to both sides and conveyed by rail between Germany and Italy. Home agriculture, corn-growing in particular, received all possible encouragement, and the country emerged from the war less impoverished than might have been expected. A careful censorship was exercised over the press; incitement was avoided, as dislike for German National Socialist activities increased and the Communist party was proscribed.

Diplomatic relations with the U.S.S.R. were reopened in 1945, and every effort was made to co-operate with international organizations that was consistent with the maintenance of the increasingly difficult principle of permanent neutrality.

Swiss currency remained remarkably stable in the 1950s but rising world prices had their effect: a number of trade agreements were negotiated and every effort made to extend exports in the face of increasing competition and tariff barriers. A country solidly opposed to Communism and to spending increased amounts on defense, it upheld its tradition of neutrality. Switzerland did not accept membership of the United Nations organization or make any direct contribution to western defense or join the Western European union.

POPULATION AND SOCIAL CONDITIONS

Switzerland has an area of 41,287 sq.km. or 15,941 sq.mi. of which 22.6% is "unproductive" (*i.e.*, bare mountains, plateau

slopes, lakes and rivers), 24.8% is occupied by forests, 24.3% consists of alpine pastures and only 28.3% is agricultural land.

Well-organized census returns were made at ten-year intervals from 1850 on, except that censuses were taken in 1888 and not in 1890, and in 1941 and not in 1940. The total population by the census of Dec. 1, 1960, was 5,429,061. This represented an increase of 714,069 or 15.1% over the figure for 1950 and was more than double that for 1850 (2,340,740). One-half of the increase since 1950 was due to natural causes and the remainder to immigration. The cantons registering the greatest gains were the industrial ones of Zürich, Zug, Basle and Geneva. (*See* Table I.) There was a steady increase in density of population from 150 per square mile in 1850 through 207 per square mile in 1900 and 255 per square mile in 1930 to 341 per square mile in 1960. The least densely populated cantons are the Alpine ones; *e.g.*, Grisons (53 per square mile) and Uri (77). The Jura cantons are much better populated: Vaud (346) and Neuchâtel (479). The densest are the cantons of Geneva (2,378), Basle Land–Basle-Stadt (2,089), and Zürich (1,428).

TABLE I.—*Area and Population of Switzerland by Cantons, 1941–60*

Cantons*	Area in sq. mi.	Population		Increase		Pop. per sq. mi. 1960
		1950	1960	Number	Per cent

*The cantons are given in the official order with the year of the entrance of each into the confederation. †Half canton.
Source: *Statistisches Jahrbuch der Schweiz 1956* (Basle, 1957).

The non-Swiss element of the population increased from 3% in 1850 to 11.6% in 1900, but fell to 8.8% in 1930; its total increased from 71,570 in 1850 to 355,522 in 1930. By 1941 there were only 223,554 aliens in the country (5.2%), the most numerous being Italians (96,018); next in order came Germans (68,622), French (24,396) and Austrians (9,652). In 1950 there were 283,367 foreigners. From 1800 to 1940 about 683,000 Swiss emigrated, mainly beyond the seas. The annual average of emigrants was 6,800 in the decade 1871–80, reached 11,500 in the years 1881–88, fell to 4,400 in the years 1889–1900, reached the peak of 11,800 in the years 1910–20 and was about 6,000 in the decade 1931–40. The number of Swiss-born residents in the United States rose steadily from 13,358 in 1850 to 124,834 in 1910; in 1940 the number was 88,293 and in 1950 71,515.

Language.—By the federal constitution of 1874, German, French and Italian are recognized as national languages for the purposes of debates in the federal parliament and for the public notification of federal laws and decrees. The recognition on July 8, 1937, of Romansh (*see* RAETO-ROMANCE DIALECTS) as a fourth national language did not affect the constitution. German predominates in 16 cantons, including even the Grisons (where, however, about one-third of the people speak Romansh in the form known as Ladin and about one-tenth Italian); French prevails in Vaud, Neuchâtel, Geneva, Fribourg and Valais; Ticino is Italian-speaking. Detailed census returns as to language had revealed a small amount of shifting. (*See* Table II.)

TABLE II.—*Distribution of Population by Language*

Year	German	French	Italian	Romansh	Others
1880	2,030,792 (71.3%)	608,007 (21.4%)	161,923 (5.7%)	38,705 (1.4%)	6,675 (0.2%)
1910	2,594,186 (69.1%)	793,264 (21.1%)	302,578 (8.1%)	40,234 (1.1%)	23,031 (0.6%)
1950	3,399,636 (72.1%)	956,889 (20.3%)	278,651 (5.9%)	48,862 (1.0%)	30,954 (0.7%)

Religion.—The constitution of 1874, while recognizing no established Swiss church, guarantees full religious liberty and freedom of worship, as well as exemption from any compulsory church rates. It repeats the constitution of 1848 in forbidding the settlement of Jesuits and their affiliated societies in Switzerland; the interdiction can be extended to any other religious orders that may endanger the safety of the state or interfere with the peace of other creeds. Protestants outnumber the Catholics in 12 cantons, of which 9 are German-speaking and 3 (Geneva, Vaud and Neuchâtel) French-speaking. The Catholics outnumber the Protestants in 10 cantons, including 7 German-speaking, 2 French-speaking (Fribourg and Valais) and the Italian-speaking Ticino.

The Roman Catholic priests are more numerous than Protestant clergy and comprise more than 6,000 priests under five diocesan bishops: viz., those of Basle and Lugano (resident at Solothurn), of Lausanne and Geneva (resident at Fribourg), of St. Gallen, of Sion (Sitten) and of Coire (Chur). (*See* Table III.)

TABLE III.—*Distribution of Population by Religion*

Year	Protestant	Catholic	Jewish	Others
1880	1,667,100 (58.6%)	1,160,782 (40.8%)	7,373 (0.2%)	10,838 (0.4%)
1910	2,107,814 (56.2%)	1,503,538 (42.4%)	15,462 (0.5%)	33,470 (0.9%)
1950	2,655,375 (56.3%)	1,959,046 (41.6%)	19,048 (0.4%)	81,523*(1.7%)

*Including 28,568 "Christian Catholics."

Cities.—In 1960, 13 towns had a population exceeding 30,000.

TABLE IV.—*Cities With Population of More Than 30,000 in 1960*

City	1850	1900	1960	City	1850	1900	1960
Zürich	41,585	168,021	440,170	Lucerne (Luzern)	10,068	29,255	67,433
Basle	27,844	109,161	206,746	Bienne (Biel)	5,609	29,557	59,216
Berne	29,670	67,550	163,172	La Chaux-de-Fonds	12,638	35,968	38,906
Geneva	37,724	97,359	176,183	Neuchâtel	7,901	21,195	33,430
Lausanne	17,108	46,732	126,328	Fribourg	9,065	15,794	32,583

Winterthur	13,651	40,961	80,352				

Education.—Under the 1848 constitution each canton or half-canton is sovereign in education. The constitution stipulates that elementary education is compulsory and free; that all public schools must be state directed; and that religious freedom be guaranteed. The confederation financially supports public elementary schools and vocational training. By regulating examinations for the professions, also influences the curriculum of the higher middle schools. The only institution of higher education maintained by the confederation is the Federal Institute of Technology at Zürich (*Eidgenössische Technische Hochschule*). The ministry of the interior in Berne is in charge of education; there is an educational department in every canton.

Children enter the primary school at the age of 6 or 7 and leave it at 14 or 15. Secondary and lower middle schools form a link between primary and higher or vocational schools. Pupils enter between the ages of 11 and 13, remaining for two to five years; they are grouped in language-history and mathematics-science branches. The technical or vocational schools serve pupils under-

going an apprenticeship between the ages of 15 and 19. The higher middle schools either take their pupils from the senior classes of a primary school or themselves provide the preparatory schooling; in the latter case the course lasts 12½ years. They prepare their pupils for the higher school certificate in three types of schools: classical (with compulsory Latin and Greek), modern language and science; there are boys', girls' and coeducational institutions.

In addition to the Federal Institute of Technology at Zürich (founded 1855), there are seven cantonal universities; viz., Basle (1460), Lausanne (1537), Geneva (1559), Zürich (1833), Berne (1834), Neuchâtel (1838) and Fribourg (1889). The commercial college of St. Gallen (1898) ranks also as an institution of higher education. At Lausanne, Geneva and Neuchâtel instruction is given only in French; at Basle, Zürich and St. Gallen only in German. Fribourg and Neuchâtel have no medical faculties. Swiss universities are lay (*laïques*), but all, except Fribourg, are in cantons of Protestant tradition. At Basle, Geneva, Lausanne, Neuchâtel and Zürich the theological faculties are Protestant; at Berne there are Protestant and Catholic faculties; at Fribourg only a Catholic one. Of the 16,501 students in 1950–51 nearly a quarter were foreigners; at Lausanne one in three students is a foreigner, at Geneva one in two. (*See* Table V.) (K. Sm.)

TABLE V.—*Education*

Type of school	Year	Pupils			Teaching staff
		Boys	Girls	Total	
Primary schools	1953–54	263,281	254,769	518,050	15,204

GOVERNMENT

The Cantons.—The political divisions are the communes (of which there are now about 3,000), districts (198), and cantons (22). Of the cantons, 19 are undivided. In 1831 the rural districts of Basle revolted against the undemocratic rule of the urban trade guild; the latter were twice defeated in the field before they agreed (in 1833) to the subdivision of the canton into Basle-Stadt and Basle Land. Unterwalden, from before 1291, was divided into Obwalden and Nidwalden, representing two distinct physical divisions in different river valleys. In 1291, Nidwalden accepted alliance with Uri and Schwyz; Obwalden did not join until later. The Reformation led to a division (1597) of Appenzell into the Inner Rhoden, mainly Roman Catholic and pastoral, and Ausser Rhoden, largely Protestant and industrial.

Each of the 22 cantons has its own legislature, executive and judiciary. The older cantons have in some instances (Unterwalden, Appenzell and Glarus) preserved their ancient democratic assemblies (*Landesgemeinden*), in which all male citizens of full age meet, usually annually during April or May, in the open air for the purpose of legislation and the selection of an annual administrative council. In the remaining cantons the legislature (*Grosser Rat* or *grand conseil*) is composed of representatives chosen by universal male suffrage and usually by proportional representation. These councils exercise all the functions of the *Landesgemeinden*. The executive also in most of the newer cantons is elected by a popular vote and not as hitherto by the cantonal legislature. All the cantons have the referendum and the popular initiative, the application of which varies in the different cantons.

The cantons are built up of two main types of communes, or *Gemeinden*. These are the real units. The burgher communes (*communes bourgeoises* or *Bürgergemeinden*) are now principally of historical interest, having for the most part been gradually absorbed by the second class of political communes. Initially burgher communes were groupings of the people to manage the "lands subject to common user" (mainly summer pastures and forests). Later, by purchase or otherwise, the burghers became possessors of manorial rights. But when the federal diet imposed the care of the poor on the several communes (1551) these naturally aided only their own burgher members. Thus, all nonburgher settlers were excluded from any share in the enjoyment of the common lands, or in their management, though they paid local rates. Increased communication facilities, together with a shifting industrial population, made such restrictions invidious and unfair, particularly after the introduction, under the Helvetic republic (1798–1801), of a federal citizenship superior to cantonal citizenship. Later, the increase of communal public duties meant financial obligations exceeding the sums produced by the common lands. To avoid some of these inconveniences, political communes (*municipalités* or *Einwohnergemeinden*) were set up. The duties of these communes were largely increased after the liberal movement of 1830; the care of the highways, the police, the schools, the administration of the poor law being successively handed over to them. Swiss citizens belonging to cantons other than those in which they resided were, by the federal constitution of 1848, given rights of voting there in cantonal and federal matters, but not in those relating exclusively to the commune itself, but the federal constitution of 1874 gave to permanent Swiss settlers communal voting rights, subject to three months' residence.

In most cantons a number of communes are grouped together to form a district (*Amtsbezirk*) under a prefect who represents the cantonal government. Minor communes are controlled by a small council. In the larger communes an executive council is chosen by a general assembly of all male Swiss citizens over 20 years of age, of good conduct and with three months' communal residence. A *maire* (*Gemeindepräsident*) is elected by the larger body to preside over the council which has the management of all local affairs, including the carrying out of cantonal and federal laws or decrees, save and except matters relating to the pastures and forests held in common.

The Confederation.—On the cessation of the federal pact in 1848 a new constitution was accepted by general consent. This is fundamentally the constitution in operation today, but sundry revisions were made in 1874 and 1931, and the amended constitution is the one now in force. Any subsequent revision can be made by normal federal legislation with a compulsory referendum on the demand of 50,000 franchised citizens, or by popular initiative. Changes require a favourable majority in total votes and total number of cantons.

Federal sovereignty is exercised by the legislative federal assembly (*Bundesversammlung*) and by the executive federal council (*Bundesrat*), both meeting at Berne. The assembly consists of two chambers: the national council (*Nationalrat*) and the council of the states (*Ständerat*).

Every whole canton is represented in the national council, on the basis (from 1950) of one member for every 24,000 people in the canton, with an additional deputy for any remainder exceeding 12,000. On the census returns of 1950 there were thus 196 representatives varying from 33 for Berne and 32 for Zürich to 1 for Uri. The deputies receive attendance pay and travelling expenses from federal funds; neither allowance is lavish. (*See* Table VI.)

TABLE VI.—*Elections to the National Council*

The council of the states consists of two members from each canton or one from each half-canton; *i.e.* 44 in all. The mode

of their election, term of membership and rate of pay are entirely cantonal matters and vary accordingly. Their average financial allowance is less than that for a deputy to the national council.

A general election of representatives to both chambers takes place every four years; voting is by proportional representation with universal male franchise for persons of 20 years of age or more, and any voter, other than a clergyman, may be elected a deputy. Laws passed by the federal assembly, though this represents both people and canton, can be vetoed as a result of a majority-supported referendum based on a popular initiative demand by 30,000 enfranchised citizens.

The seven members of the federal council or government are elected for four years by the federal assembly and are responsible for the following departments: foreign affairs; justice and pelice; interior; defense; finance and customs; public economy; and railways and post office. No canton may have more than one representative in the federal council; but according to custom it should always include a Bernese, a Zurichese and a Vaudois. Usually four members are German-speaking, two French-speaking and one Italian-speaking.

The president of the federal council and the vice-president of the federal council (who is one of its seven members) are elected for one year only (Jan. 1–Dec. 31) by the federal assembly and cannot be immediately re-elected. Federal councilors cannot hold a plurality of office, either federal or cantonal, and must not engage in any profession or trade. The federal government (assembly and council) is being increasingly entrusted with matters formerly considered to be purely cantonal.

Justice.—Each canton elects, controls and pays (often merely a nominal sum, even if the posts are not entirely honorary) its own magistracy for ordinary civil and criminal trials. There are cantonal variations in the penal code, *e.g.*, capital punishment exists only in nine cantons and one half-canton.

The federal supreme court (*Bundesgericht*) sits at Lausanne. There are 26–28 full members (plus 9 supplementary judges), elected by the federal assembly to hold office for six years with eligibility for re-election. The federal assembly also elects every two years the president and vice-president who, as such, cannot be re-elected. The original and final jurisdiction of the *Bundesgericht* extends to disputes between the confederation, the cantons, corporations, and private individuals, so far as these differences refer to federal matters and involve more than 4,000 Fr. in financial suits. It is a court of appeal against cantonal authorities in the application of federal laws and also against decisions of other federal departments. It is a court of trial for persons accused of treason, or other offenses against the confederation. The four courts of the *Bundesgericht* are: the court of accusation, the criminal court (with paid jurors elected by the people), the federal penal court and the court of cassation. (W. E. Wh.; X.)

DEFENSE

The Militia System.—Being composed of militia, the Swiss army contains no forces maintained permanently with the colours except a corps of 327 instructors: a system which is unique in Europe. The total number of men physically fit and trained for military duty was approximately 700,000 in 1952.

All male citizens are liable to military service from the beginning of the year in which their 20th birthday falls until the year of their 48th birthday. Service may be rendered either personally or by the payment of a military tax. Volunteering before the legal age is permitted. The military tax is payable up to the age of 48. Enlistment takes place in the year of the 19th birthday. Personal service includes attendance for training, active service at home or abroad in defense of the country, and maintenance of public order and security. Men passed fit for auxiliary service pay a tax in lieu of military training for the years in which it would otherwise be performed. After physical training for boys, provided by the cantons under the supervision of the federal government, the training is carried out under the military department.

The army consists of a first line (*Auszug* or *élite*) for ages from 20 to 32 inclusive, *Landwehr* for ages from 33 to 42 inclusive, and *Landsturm* for ages from 43 to 48 inclusive. After a recruit course varying from 62 to 118 days according to the arm of the service envisaged, members of the *élite* undergo seven 20-day annual trainings. Men in the *Landwehr* and the *Landsturm* are called up for a few repetition trainings (*Wiederholungskurse*) not exceeding 60 days in all. Officers are trained in cadet schools, courses lasting from 62 to 104 days, according to the arm of the service envisaged.

As the militia keep their rifles in their own houses, the whole army can be mobilized in 48 hr. In 1939 about 500,000 were mobilized, but after the collapse of France in 1940 the number under arms was reduced to 250,000.

Order of Battle.—The country is divided into nine divisional districts. There are also four independent mountain brigades and three armoured brigades. There is a staff organization for four army corps.

The 37 infantry regiments are armed with special infantry guns and mortars and anti-tank guns. The 17 artillery regiments are armed with 105-mm. guns and 105-mm. and 150-mm. howitzers. There is a small air force, which by 1953 had 170 jet fighter aircraft in the first line.

In 1950 Switzerland started an extraordinary rearmament program, the total cost of which amounted to about 1,400,000,000 Fr. In 1950 the total military expenditure amounted to 480,000,000 Fr., four times as much as in 1938. The military estimates for 1956 amounted to 673,000,000 Fr.

Higher Command.—In peacetime the Swiss army has no general, colonel being the highest rank. One of the seven federal councillors is head of the military department, the central authority in peacetime for national defense. If troops are mobilized on a large scale the federal assembly appoints a commander in chief, as it did in 1939 when Gen. Henri Guisan was appointed. There is a general staff under the military department and a national defense committee, with the head of the military department as chairman and the chief of the general staff and with four army corps commanders and the officer commanding infantry as members. The committee ceases to function when a commander in chief is appointed.

ECONOMIC CONDITIONS

According to the census of 1950, the economically active population was employed as follows: 46.6% in the manufacturing industry, handicrafts, building, mining and quarrying; 16.5% in agriculture and forestry; 11.8% in commerce, banking and insurance; 7.6% in public administration and the professions; 4.2% in the hotel industry; 4.5% in transport and communications; and the rest in domestic and other services. As these proportions clearly show, Switzerland is preponderantly an industrial country, depending for its existence and prosperity on the export of machinery, apparatus and instruments. This is all the more surprising as the country has practically no useful mineral resources except salt and is entirely landlocked, without direct access to overseas markets. Apparently condemned by nature to a meagre pastoral economy, the Swiss by hard work, inventiveness and perseverance have succeeded in developing other industries but their hold is always precarious. (*See* Table VII).

TABLE VII.—*Economically Active Population*

Category	1910	1930	1950
Agriculture, forestry, fishing	477,118	413,366	355,427
Mining and quarrying	6,009	7,531	6,263
Manufacturing, handicrafts, building	805,148	852,371	908,041
Commerce, banking, insurance	117,500	190,520	252,481
Hotels	78,159	94,321	90,791
Transport and communications	84,734	84,998	98,014
Public administration and professions	80,900	116,714	164,252
Domestic service	105,935	133,902	111,723
Day labourers	8,640	6,448	4,881
Institutions with resident staff	12,902	42,495	64,831
Unemployed			8,952
Total	1,783,195	1,942,626	2,155,056

Agriculture.—The mountainous character of the large part of Switzerland, the high average altitude, the excessive rainfall and the prevailing system of small holdings all combine to prevent the country from being preponderantly agricultural. From the middle of the 19th century the rural population has declined: in 1888 the proportion of the economically active population engaged in agriculture was 37% as compared with 20.8% in 1941. At the same time the country has become increasingly dependent on imports for its food supply, especially for its bread grain. By 1850 the grain production was sufficient to cover about two-thirds of domestic requirements; in 1934–48 this proportion was reduced to one-third. Switzerland is predestined rather to be a cattle-raising country. Milk production per cow is high and reaches about 2,900 kg. or 740 gal. annually; *cf.* an average of about 500 gal. in the United States. (*See* Tables VIII, IX and X.)

Industry.—Practically all raw materials, be they minerals or vegetable or animal fibres, are imported; and hydraulic power is the only source of energy to be found in the country. Having no appreciable home market and being not only stifled by the protectionist policies of all their customers abroad but also burdened with very

as complicated machinery, durable consumers' goods such as watches or hoots and shoes, and luxury products of the textile industry.

Switzerland is richly endowed by nature in hydroelectric potentialities. Its total installed capacity rose between 1929 and 1955 from 1,520.000 kw. to 3,720,000 kw. (incl. 3,520,000 kw. from hydroelectric power stations). The production of electric power rose between 1937 and 1956 from 6,842,000,000 kw.hr. to 14,892,000,000 kw.hr. Switzerland has the fifth highest output of electricity per capita in the world (after Norway, Canada, Sweden and the United States). The production of cement in 1956 was 2,379,000 metric tons (as compared with 995,000 tons in 1947).

Foreign Trade.—The importance of foreign trade for Switzerland is reflected in the annual value per head of the population of imports and exports together. In 1938 that figure, in Swiss francs, was 464; *cf.* 564 for Belgium, 523 for the Netherlands and, on the other hand, 430 for Great Britain. Imports, consisting of such necessities as raw

materials, fuel and food, surpass exports in value, but the resulting deficit is generally covered by the tourist trade. (*See* Table XI.)

Watches, clocks and parts were both before and after World War II the most important Swiss exports, amounting to 20% of the total in 1956; machinery represented in that year 21% and textiles 14%. Main imports in 1952 were: machinery and vehicles 12%; steel mill products 10%; coal and petroleum 10%; grain 6%; textile fibres 5%.

Whereas in 1938 Germany had been Switzerland's most important customer (16% of the total) with the United Kingdom in the second place (11%) and France in the third (9%), by 1954 the United States and Canada took most of the Swiss exports (14%), followed by Germany (12%) and then by France (7%). In 1938 Germany was also the main source of Swiss imports (23%), with France in the second place (14%) and the United States in the third (8%); by 1954 Germany recovered its first place (22%), with the United States and Canada second (16%) and France third (13%).

Transport and Communications.—In 1956 Switzerland had 49,000 km. of roads, 308,679 motor cars, 2,594 buses and 59,189 trucks. There were 2,976 km. (route length) of railways, of which 2,810 km. were electrified. (*See* also ALPS for principal passes and tunnels.) In 1956 the state railway goods traffic amounted to 3,264,000,000 ton-km. (as compared with 1,710,000,000 ton-km. in 1938). That of passenger traffic amounted in 1954 to 6,954,000,000 pass.-km. (as compared with 3,297,000,000 pass.-km. in 1938). The traffic on the national airlines (Swissair) in 1956 amounted to 603,600,000 pass.-km. (as compared with 13,575,000 pass.-km. in 1938) and for cargo, including mail, to 15,276,000 ton-km. (as compared with 268,000 ton-km. in 1938). In 1956 there were 1,293,743 telephones, 1,267,824 licensed radio sets and 19,971 television sets.

Federal Finances.—The principal expenditure of the confederation is under the heads of defense, social insurance, contributions toward the promotion of economy and administration. Until World War I the main revenue of the confederation was from indirect taxes (customs duties and stamp duty), while direct taxes were levied only by cantons and communes. In 1915 federal taxes on property and income were introduced. (*See* Table XII.)

TABLE XII.—*Federal Finance*
(In millions of francs)

	1913	1938	1952	1953	1954	1955	1956
Revenue	101	731	1,949.9	1,974.8	2,320.4	2,245.3	2,610.6
Expenditure	106	772	2,161.5	1,884.1	1,959.2	1,948.7	1,963.6

The unit of currency is the franc of 100 Rappen or centimes. The exchange rate of the franc on Dec. 31, 1955, was 4.284 Fr. per U.S. dollar (as compared with 4.338 Fr. on Dec. 31, 1938). The Swiss National bank, founded in 1907, is the central bank of issue. On Dec. 31, 1956, it had gold reserves of U.S. $1,676,000,000 and foreign exchange to the amount of U.S. $238,000,000, compared with a note issue of 6,240,000,000 Fr. and deposit money of 8,360,000,000 Fr.

SWOLD, BATTLE OF: *see* OLAF I TRYGGVESSÖN.

SWORD, a hand weapon with a sharp metal blade that is longer than that of a dagger, though the distinction is somewhat arbitrary. "Sword" is a general term that includes many special types of weapons, such as sabres, rapiers, scimitars, etc.

Early History.—It is possible that the earliest swords derived from the flint dagger of the Neolithic period, which may have been the model for the first hand weapons made of copper. Daggers with copper blades found in Mycenae have hilts attached to the blades by rivets. An important step in the construction of both sword and dagger was taken when the blade was continued in an extension, or tang, which became the core of the handle. The blade and hilt could thus not easily be broken apart by a blow. Most swords of the Bronze Age had leaf-shaped blades and small hilts. They have been excavated in large numbers throughout Europe. Swords of this kind (*ziphos; akinakes*) were used in the Homeric period, and are shown in paintings on Greek vases of the Hellenic period. Alternatively to the straight-edged, leaf-shaped sword was the so-called Bronze Age rapier, a sword with a long narrow blade for thrusting only. Its opposite was the *machaera* or *kopis*, whose blade had a double curve and a single cutting edge.

During the Hallstatt period when iron was used in addition to bronze, for the first time iron blades were fitted with hilts of bronze or other material.

In classical times the sword as a weapon was subsidiary to the spear. The Roman soldier's sword (*gladius*) was generally short, straight and broad, though a longer type of sword, known as the spatha, was also used. The word ensis was generally applied to swords of tribes outside the empire.

The Franks of the late Iron Age continued to use the long spatha, but as it was made of soft iron, the blade was easily bent. Some protection for the hands was given in early swords by the form of the hilt, but it was not until the early middle ages that the crossbar, or *quillons*, became fully developed for protective purposes.

The swords of the 5th century, found in the bog at Nydam, Schleswig, show waisted grips. By the 6th century Viking swords began to take the form which lasted for a thousand years. The sword had then acquired its four principal parts: (1) the pommel, a knob at the anterior end, which acted as a counterpoise to the blade; (2) the grip, covering the tang and grasped by the hands; (3) the crossbar or *quillons*, which protected the user's hand, and (4) the blade. (*See* figure.)

The Middle Ages.—It was the Vikings from Scandinavia who introduced the sword with the blade of carbonized iron. There has always been a mystery about the making of sword blades, hence the legends of Weyland the Smith, Siegfried's sword "Nothung" and King Arthur's "Excalibur." Modern science

TECHNICAL NAMES OF THE PARTS OF A SWORD

has discovered that some of these blades, which have patterns or "watering" inherent in them, were produced by what is called strip welding. Bundles of iron strips were bent over, hammered together, cut and bent again repeatedly, and the carbonization of metal, probably discovered accidentally, improved their strength and temper.

The Viking sword, and its successor, the medieval knightly sword, usually had a straight blade, double-edged and pointed, with a shallow hollow down the centre, giving lightness with rigidity. The medieval sword was purely an offensive weapon; the user relied for bodily protection on his shield and defensive armour. The user's hand was protected by rigid *quillons,* either straight or with the ends curved toward the blade. The pommel was usually rounded, either as a sphere or a disk (so-called wheel pommel) and later fig-shaped.

In the course of years certain European centres of the craft were established, notably at Passau on the Danube, and later at Solingen in western Germany, where the craft was still active in the mid-20th century. Blades were exported from Solingen to all parts of Europe, often bearing the mark of a running wolf. Swords bearing distinctive names, denoting a common origin, were widely distributed in Europe, such as those inscribed Ulfbehrt and Ingelred. Other centres of the sword cutler's craft were places where the making of arms and armour in general had been established, notably in Milan in north Italy, and in the south German towns of Nürnberg and Augsburg. In Spain great skill was shown by the swordsmiths of Toledo. The names of many master craftsmen are known and are found engraved upon the blades themselves, which also carry the marks of the maker and often the city guild where they were proved.

In the late middle ages the knightly sword was sometimes lengthened, both in blade and hilt, and the latter so shaped that it could be grasped by both hands if necessary. In the 15th century the blades of straight-bladed swords were more usually double-edged and flat, sometimes stiffened by a sharp ridge down the centre. This was particularly the case in Italy. A purely thrusting sword, with a rigid blade, was known as an *estoc.* At the turn of the century the big two-handed sword had a short vogue, but the space required for wielding it limited its advantages.

In order to have better control of the weapon, a custom developed of passing the right forefinger over the *quillons.* To protect it, a metal hook or ring was placed in front of the *quillons.* The next step was to place a corresponding half ring on the other side of the blade for the sake of symmetry. This development, nicknamed the *pas d'âne* from its resemblance to a cloven hoof mark, apparently developed first in Spain and then passed to Italy before the end of the 15th century. It is important as foreshadowing the development of the hilt whereby the hand was protected by a cagelike series of rings and bars forming part of the sword, instead of by a steel glove.

The Later Sword.—The sword underwent rapid changes in Europe during the first half of the 16th century, and proliferated in a variety of forms. These changes correspond with the period when defensive armour was beginning to fall into disuse, and special corps of soldiery were becoming components of national armies. The protection of the hand was carried a step farther by the provision of a knuckle bow; *i.e.,* a semicircular bar extending from the *quillons* toward the pommel. The next move was to add additional rings to guard the whole hand, both in the vertical and the horizontal planes. The old arming sword, which was wielded with a gauntleted hand, had been strictly cruciform. The 16th century saw the arrival of the rapier, with a long, narrow blade, and with the hand protected by a series of guards and counterguards.

The habit of carrying a sword with civilian dress had not been universal in the middle ages but it later became the custom for every gentleman to carry a rapier in civil life, and in consequence dueling increased. Previously, dueling had taken the form of judicial combats, conducted with strict formality. Dueling with a rapier rapidly encouraged the art of fencing. Schools conducted by masters of fence were set up in which gentlemen learned their skill at arms. The earliest known fencing book is a treatise, *Flos Duellatorum* or *Il Fior di Battaglia,* by Maestro Fiore dei Liberi (compiled in Italy in 1410). It demonstrated in a series of drawings combats with swords, sword and buckler, wrestling, etc. It was followed in the 15th century by a picture book by H. Talhofer, of which several manuscript versions exist. In the 16th century, books on fencing came from the printing presses, generally written by one of the masters of the schools of fencing, such as A. Marozzo and C. Agrippa in Italy, H. de St. Didier in France and George Silver, who was a stout defender of the rough-and-ready English fashion against his rival, "Signior" Rocco, an Italian who had set up his own school in London. The weapons used in dueling could be rapier and dagger, the latter held in the left hand and used for parrying, rapier and cloak, or two rapiers, but eventually fencing with the rapier or smallsword alone prevailed. At first both edge and point were used, but with the increase of manual dexterity it was found that the point, which allowed a long reach, was more effective by itself. The swordsman was liable to lay himself open when he used striking blows, so thrusting, parrying and feinting within a narrow compass became a practised art. (*See* also FENCING.)

The hilts of rapiers took many forms, often being richly decorated with gold and silver, damascening, enameling and even incrustation with jewels. Fine specimens are to be seen in the national armouries of Vienna, Madrid and Paris. Notable swordmakers were A. Piccinino of Milan, L. Palumbo of Naples, the Wundes family and Clemens Horn, among many, at Solingen, and Juan Martinez, Tomas de Ayala and Sebastian Hernandez at Toledo. The blades of most rapiers bear the signature of the maker, his town, and the stamp of the city guild, which is usually placed upon the *ricasso* (the base of the blade), which usually has a rectangular section. Many of these long, narrow, thrusting blades made in Germany were stamped with imitations of the ♀ stamp of Toledo. Blades of all kinds were made in Germany, inscribed with the names of swordsmiths who may be regarded as having specialized in blades of a certain kind, such as A. Sahagun and Andrea Ferrara. The last name is quite commonly found on the blades of broadswords of the 17th century and is no indication of the actual maker. The blade is classified in two parts, the forte which is the anterior part, and the foible which is the forward part farthest from the hilt. In Spain a particularly elegant form of rapier hilt was developed in which the principal protection of the hand was a steel cup, often beautifully pierced with decorations. This developed at Toledo, but soon spread throughout much of western Europe. Generally speaking, those made in the south had deep cups while those produced in the Low Countries and England had shallower "dish" guards.

In the third quarter of the 17th century the rapier was reduced in size and simplified to what became known as the smallsword. This too was principally a civilian weapon, and the subject of much delicate and elaborate ornamentation, following the trends of fashion through the 18th century. The blade of the smallsword was purely for thrusting, and usually given a hollow, triangular section. In other cases the blades were hexagonal, diamond-shaped or even elliptical in section.

New weapons produced their own writers on swordsmanship, notably the Scotsman, Sir William Hope, who wrote a number of manuals in the late 17th and early 18th centuries. H. Angelo's school of fencing in London is well known from his books illustrated by George Rowlandson.

Swords for specialized use and local types are legion, such as the straight broadsword with S-shaped *quillons* used by the German *Landsknechte* (professional infantry) in Germany and Switzerland in the 16th century. In the highlands of Scotland the two-handed sword lasted to the end of the 17th century in the form of the big *claidheammor* (great sword; whence "claymore") with drooping *quillons* ending in quatrefoils, and Scotland produced a characteristic variety of the basket-hilted broadsword.

The medieval arming sword had been replaced for war by the sword rapier, a heavier version of the civilian sword. Its successor was the cavalry broadsword, a simple and handy weapon on which the knuckles were protected by a single or basketlike guard, and the blade was flat and broad, sometimes double-edged and sometimes single, when it was called a backsword. Many broadswords of this type have come down from the time of the Civil War in England. Sometimes the solid guards of the hilts are chased with the heads of Charles I and his queen, and these are popularly called "mortuary" swords, referring to the execution of the king.

The military form of the smallsword during the 18th century was more heavily built, and was furnished with a single knuckle bow and a pair of oval-shaped plaques in front of the *pas d'ane*. The creation of standing armies with regiments uniformly equipped resulted in swords of regulation patterns.

The Curved Sword and the East.—The sabre is essentially a cutting weapon, with the blade sharpened on the convex edge only. It cuts well because only a small part of the arc first reaches the objective, and then bites into it.

Whereas the straight sword was the favourite in the west, the curved sword predominated in eastern Europe and Asia, although curved swords were not unknown in the west. In the middle ages there was the falchion, a sword with a cleaverlike blade, broadening toward the point and with a single curved cutting edge. That it was regarded as an oriental weapon is shown by the fact that in medieval manuscripts the sleeping guards at the Sepulchre are shown with falchions. The common people of England practised on foot as a sport with sword and buckler, when those more wealthy jousted with lances on horseback. In the 17th century light, curved riding swords or hangers were much used in Europe, and from this followed the cutlass. Hunting swords with appropriate decoration, used for deer and boar, form a class by themselves.

The Turkish invasion of Europe in the 16th century brought the west into close contact with the curved weapons of the east. The scimitar, which has a keen arc-shaped edge, derived from the Persian shamsheer. It was brought into Hungary and Poland, and western cavalry regiments in the late 18th and 19th centuries were armed with the curved sabre which derived directly from the east. Turkish and Persian scimitars were often made with finely watered blades. These blades are often described as damascened, but Damascus was never a centre of the craft, only an entrepôt. Fine swords were made at Ispahan in Persia, at Constantinople, at Cairo under the Mamelukes and at Fez in north Africa. The north and middle European scimitar generally has a pistol-shape grip, which continues the curve of the blade in the opposite direction.

In India the scimitar has always had a permanent place, and is called a tulwar. Among other Indian swords are the Maratha khanda and the gauntlet sword known as a pata, and in Burma the *dha*. The Ghurka kukri has a doubly curved blade, and in skillful hands can be used to decapitate an ox at one blow.

In Japan the sword has long been taken seriously. As early as the 13th–14th centuries great masters of the craft were making blades of remarkable quality, such as Yoshimitsu and Masamune. The possession of a sword is closely connected with the cult of ancestor worship, and swords were handed from one generation to another as objects of veneration. The Japanese sword has a long, slightly curved, single-edged blade and a grip in which the curve is extended in the same direction as that of the blade, with ample room for being gripped by two hands. The guards (tsubas), which are small and solid, are objects of special decoration; an owner might have as many as sixty different sword guards with which to furnish his sword, ringing the changes as he felt appropriate. Among the various kinds of Japanese swords are the *daisho*, a pair of swords, the larger being called a *katana* and the smaller a *wakizashi*. Japanese swordsmanship was possibly an even greater cult in that country than it was in the west, and expressed itself in formal and elaborate dueling. The sword which the Japanese commander in chief, Count Juichi Terauchi, tendered to Admiral Lord Mountbatten when he surrendered in 1945 is now at Windsor castle.

In north Africa one finds a liking for the straight two-edged blade of western type. This type of sword is known as a *kaskara*. It is often said that these swords derived from the crusades, but a glance will show that in construction they have one important difference. The heavy pommel of the European medieval sword is missing from the *kaskara*, which has only a light disk.

The Modern Sword.—Since the middle of the 18th century the sabre has been predominant. Indeed, if one accepts the definition of a sabre as a sword with a single edge designed primarily for cutting, regardless of whether the blade is curved or straight, it becomes apparent that more than 80% of all European and American swords of the period fall within this category. The civilian small sword had virtually disappeared by 1800. Diplomats and some staff officers continued to wear small swords of one type or another, but their numbers were few. Among the military sabres, those used by the cavalry were most important as weapons. The first sabres to be used by horsemen were usually straight or very slightly curved. Early in the 19th century the curve increased. Then, with the discovery that the point was used more often than the edge, the straight blade returned to favour in almost every European nation and in America. Another form of sabre, the naval cutlass, achieved its distinction during this era. It was a short weapon with a straight or slightly curved blade and a heavy guard suitable for fighting in close quarters and easily carried while climbing. It maintained its basic design without change until the long-range naval actions of the twentieth century rendered it obsolete.

Officers and ranking noncommissioned officers of almost all arms and branches of service carried swords at some time during the 19th century. Indeed, the sword was used to designate the rank and branch of service of the wearer as well as to provide for his defense. For this reason the swords of the last two hundred years are found in a greater variety of styles and forms than for any other comparable period.

As long as firearms were single-shot weapons and firepower was relatively low, the sword remained a vital weapon. During the American Revolution, cavalry leaders considered the sword the only true weapon of a trooper and scorned the use of firearms except for skirmish or picket duty. Infantry officers participated in charges with sword in hand or stood by with that weapon to help repel an enemy attack.

The adoption of repeating arms ended the sword's importance. As late as the U.S. Civil War cavalry still charged with sabre in hand, but the concept of the trooper as a mounted infantryman was developing. His revolver and his repeating carbine carried more weight than his sword. The last traditional cavalry charge by U.S. troops occurred on Luzon in 1906. There were some isolated actions by European cavalrymen during World War I and again on the eastern front in World War II, but these were anachronisms. The era of the sabre as a weapon had ended. As

a symbol of rank and of arm of service, however, it is still in use, and it has been found to serve an important function from the standpoint of morale and the sense of tradition.

Presentation and State Swords.—A special category of swords comprises those used in state ceremonies and those presented to individuals as a mark of esteem or honour. The ceremonial or state swords have been used for many centuries at coronations, inaugurations and other solemn public occasions. Among them are the sword of justice, the sword of mercy and the sword of mourning. Usually they are huge two-handed swords richly mounted in precious metals, often set with gems, and frequently bearing the arms of the country, state or city to which they belong. Such swords have figured in the regalia of almost every European monarchy, and some are still in use. Special presentation swords or swords of honour have a much shorter history. The practice of giving a sword as a mark of esteem or as recognition for a heroic deed is as old as the sword itself. The manufacture of special swords for this purpose, however, did not achieve widespread popularity until the 18th century. From then until the third quarter of the 19th century huge quantities of them were made and presented by nations, states, cities, organizations and individuals. Some were even awarded by "vote" in lotteries during the U.S. Civil War. After 1875 the practice rapidly declined in popularity, although it has not yet died out completely. A few were presented to leading generals at the close of World War II. Usually these presentation swords were patterned after the principal swords of the day but distinguished from them by the richness of their mountings. In the 18th century they were primarily small swords; in the 19th century they were sabres. Most recently, however, there has been a tendency to revert to the medieval arming sword. Most of those presented at the close of World War II, in fact, were of this traditional form.

The Headsman's Sword.—One last class of sword may also be mentioned—the "heading" sword or executioner's sword. In many countries, both in Europe and Asia, it was often the practice to decapitate condemned criminals with the sword instead of the ax. Queen Anne Boleyn was beheaded with a sword at the Tower of London in 1536, for instance, and even in the United States at least one such execution is recorded in Massachusetts in 1644. In Asia the practice continued and was still being used as late as the end of World War II. The European "heading" sword traditionally had a long straight blade with a square "point." The balance was forward; the hilt was cruciform with grips long enough to permit the use of both hands. Asian swords, while also normally possessing the two-handed grips, tended to have slightly curved blades.

SWORDFISH (*Xiphias gladius*), a large fish, widely distributed in warm seas, dark purplish in colour, and with the snout prolonged to form a long, flat "sword." As in the mackerels, to which it is related, the caudal peduncle is slender and the caudal fin is widely forked. It reaches a weight of about 1,000 lb. It swims swiftly at the surface and feeds on other fishes, especially mackerel, and is said to dash into a school, killing a number with slashes of its long sword. The flesh of the swordfish is valued as food; fisheries exist in the Mediterranean and off the Atlantic coast of America, the usual method being harpooning. The record swordfish taken with rod and reel was 13 ft. 9 in. long and weighed 860 lb.

Related to the swordfish are the spearfishes (*Tetrapturus*), marlins (*Makaira*) and sailfishes (*Istiophorus*): in these the rostrum is not flattened, but is spearlike, rounded in transverse section. Each genus has two or three species, all large fishes of warm seas. *Istiophorus americanus* of the Atlantic is a beautiful fish, silvery and blue-backed, with the very large saillike dorsal fin deep blue, with numerous round black spots. The members of this group are said to attack whales, and whereas this is doubtful, it is certain that they frequently strike ships, possibly mistaking them for whales. The sword or spear may be driven into a wooden ship with such force that the fish, in order to get free, has to break it off short. In the Natural History museum in London is a piece of timber, less than a foot square, containing the broken ends of three spears.

SWYNFORD, CATHERINE (*c.* 1350–1403), wife of John of Gaunt, duke of Lancaster, was a daughter of Sir Paon Roet (Sir Payne Roelt), a knight who came to England from Hainault in the train of Edward III's queen, Philippa. About 1367 she married Sir Hugh Swynford (1340–1372), a Lincolnshire man, by whom she had a son, Thomas (*c.* 1368–1433), who was a friend and companion of Henry IV.

Soon after her husband's death in 1372 Catherine became the mistress of John of Gaunt, and in 1396 she was married to him at Lincoln. She died at Lincoln on May 10, 1403. By John of Gaunt Catherine had four children, all of whom were born before their marriage. They were declared legitimate in 1397 and took the name of Beaufort from one of their father's castles in Anjou. *See* BEAUFORT.

SYAGRIUS (d. 487), the last of the independent Roman administrators of Gaul, was the son of Aegidius, who had seized Gaul while Ricimer was master of Italy. Defeated in 486 by Clovis, king of the Salian Franks, at the battle of Soissons, Syagrius fled, leaving his land at the mercy of the Franks. He sought refuge with Alaric II, king of the Visigoths, at Toulouse, but Alaric imprisoned him instead of granting him refuge, and delivered him up to Clovis. He was executed in 487, secretly and by the sword, according to Gregory of Tours.

SYBARIS, a city of Magna Graecia, on the Gulf of Tarentum, between the rivers Crathis (Crati) and Sybaris (Coscile), which meet 3 mi. from the sea, but in ancient times had independent mouths, was the oldest Greek colony in this region. It was an Achaean colony founded by Isus of Helice (about 720 B.C.), but had among its settlers many Troezenians, who were ultimately expelled. Placed in a very fertile, though unhealthful, region, and following a liberal policy in the admission of citizens from all quarters, the city became great and opulent, with a vast subject territory and daughter colonies even on the Tyrrhenian sea (Posidonia, Laus, Scidrus). For magnificence and luxury the Sybarites were pro-

verbial throughout Greece, and in the 6th century no Hellenic city could compare with its wealth and splendour. At length contests between the democrats and oligarchs in which many of the latter were expelled and took refuge at Crotona, led to a war with that city, and the Crotoniats, with inferior forces, were victorious. They razed Sybaris to the ground and turned the waters of the Crathis over its ruins (510 B.C.). Explorations have so far failed to lead to a precise knowledge of the site. The only discoveries have been (1) that of an extensive necropolis, about 8 mi. to the west of the confluence of the two rivers, of the end of the first Iron Age, known as that of Torre Mordillo, the contents of which are preserved at Potenza; (2) that of a necropolis of about 400 B.C.—the period of the greatest prosperity of Thurii (*q.v.*)—consisting of tombs covered by tumuli, in some of which were found fine gold plates with mystic inscriptions in Greek characters.

SYBEL, HEINRICH VON (1817–1895), German historian, was born on Dec. 2, 1817, at Düsseldorf. Sybel was educated at the gymnasium of his native town, and then at the University of Berlin, where he came under the influence of Savigny and of Ranke, whose most distinguished pupil he was to become. In 1841 he settled at Bonn as *Privatdozent* in history. He was already known by his *Geschichte des ersten Kreuzzuges* (Düsseldorf, 1841; new ed., Leipzig, 1881; Eng. trans. by Lady Duff-Gordon, 1861). This was followed by a study on the growth of German kingship (*Die Entstehung des deutschen Königtums*, Frankfurt, 1844, and again 1881), after which he was appointed professor. In the same year (1844) Sybel came forward as an opponent of the Ultramontane party. In 1846 he was appointed professor at Marburg, while a seat in the Hessian *landtag* gave him his first experience of political affairs. In 1848 he was present at Frankfurt, but did not sit in the national assembly. His opposition to the revolutionary party made him unpopular with the mob, who broke his windows, as his liberalism made him suspected at court. He sat in the Erfurt parliament of 1850, and was attached to the Gotha party, which hoped for the regeneration of Germany through the ascendancy of Prussia. During the years of reaction that followed all political activity was impossible, but he was fully occupied with his great work, *Geschichte der Revolutionzeit 1789–1800*, for which he had made prolonged studies in the archives at Paris and elsewhere. The later editions of the earlier volumes are much enlarged and altered, and a new edition was published at Stuttgart in 1882. The first three volumes have been translated into English by W. C. Perry (1867–69). In this work he for the first time showed the connection between the internal and external history of France.

In 1856 Sybel accepted the post of professor at Munich. There he founded the *Historische Zeitschrift*, the original and model of numerous technical historical publications. In 1861 he accepted a professorship at Bonn, which he held till 1875. He was at once elected a member of the Prussian lower house, and during the next three years was an active member, opposing the policy of Bismarck, not only on financial but also on the Polish and Danish affairs. In 1864 he did not stand for re-election. He had a seat in the constituent assembly of 1867, and while he joined the National Liberals he distinguished himself by his opposition to the introduction of universal suffrage, the effects of which he, as did many other Liberals, much distrusted. In 1874 he again accepted a seat in the Prussian parliament. In 1880 he retired.

In 1875 he had been appointed by Bismarck director of the Prussian archives. Under his superintendence was begun the great series of publications, besides that of the correspondence of Frederick the Great, in the editing of which he himself took part. His last years were occupied on his great work, *Die Begründung des deutschen Reiches durch Wilhelm I* (7 vol., Munich, 1889–94; Eng. trans., 1890–91). He died at Marburg Aug. 1, 1895.

SYCAMORE, the name applied to American species of plane trees of the genus *Platanus*, which also embraces the European and Asiatic planes and in Europe to a species of maple (*q.v.*). The distinctive eastern sycamore (*Platanus occidentalis*), also known in certain localities as buttonwood or American plane, is probably the largest hardwood species in the eastern United States. Best development is attained on rich alluvial bottomlands, where it often reaches a height of 150 ft. and a diameter of 8 to 12 ft. It is occasionally found in pure groves, but is much more common as an occasional tree in association with other bottomland hardwood species such as river birch, red and silver maples, American elm, cottonwood and willows. Sycamore features large, simple, shallowly three- to seven-palmately-lobed leaves, each with a long petiole or leafstalk swollen at the base and enclosing next year's bud. A pair of large leafy outgrowths or stipules at each node is another conspicuous feature.

The flowers are unisexual. Both sexes are borne in separate, solitary heads that appear in advance of the leaves. The fruit is a multiple head of obovoid achenes, each furnished at the base with a fringe of brown silken hairs.

Winter characters are also distinctive. The stout, brown, conspicuously zigzag twigs feature alternately disposed conical buds that are capped with a single scale and nearly surrounded by a leaf scar. Above each leaf scar is a prominent stipule scar which encircles the twig. The bark on small branches is creamy white; that on larger limbs and the trunk (except near the base of large trees) is characterized by the annual exfoliation of the brown outer

SYCAMORE (PLATANUS OCCIDENTALIS) SHOWING THE BROWN, OUTER LAYERS OF BARK WITH THE WHITE LAYERS BENEATH THEM (TOP), A LEAF (BOTTOM LEFT) AND STAMINATE FLOWERS (BOTTOM RIGHT)

layers to expose the lighter yellowish to white layers immediately below.

The Arizona sycamore (*P. wrightii*) is one of the most abundant hardwoods of southwestern United States. The tree features deeply five- to seven-lobed leaves and the multiple heads of achenes are borne in racemose clusters of from two to four. The California sycamore, *P. racemosa*, a medium-sized tree of the coast

ranges and lower Sierra Nevada mountains of California, features three- to five-lobed leaves, and fruit in racemose clusters of two to seven.

SYDENHAM, THOMAS (1624–1689), one of the greatest English physicians of the 17th century, was born on Sept. 10, 1624, in Wynford Eagle, Dorset. His medical studies at Oxford were interrupted by the Civil War, in which he served for four years in Oliver Cromwell's army. After graduation from Oxford, he studied at Montpellier, Fr., and then set up practice in London. His greatest contributions to contemporary medicine were his careful observations and records of diseases and his revival of the Hippocratic outlook at a time when superstition and mysticism had crept into medicine. His simple and classic descriptions of disease are contained in various publications such as *Medical Observations* in 1676 and *A Treatise on Gout* in 1683. He insisted that in treatment, observations should have precedent over theory. He treated fevers by cooling, introduced "Sydenham's laudanum," a tincture of opium, and popularized the use of Peruvian (cinchona) bark in treating malaria. He died in London on Dec. 29, 1689.

See C. E. A. Winslow, *The Conquest of Epidemic Disease* (Princeton, N.J., 1943).

SYDENHAM, a residential area almost wholly in Lewisham (*q.v.*), but also extending into Camberwell (*q.v.*), London, Eng. Its development dates from the re-erection there (1854) of the Crystal palace (burned down 1936). Sydenham Wells park contains the site of medicinal springs popular in the 17th and 18th centuries. Former residents included the actress Sarah Siddons, the poet Thomas Campbell and the colour printer George Baxter.

SYDNEY, a city situated in the Sydney basin (County Cumberland) is the capital of New South Wales, Austr., and lies (lat. 33° 52′ S., long. 151° 12′ E.) mainly on the south shore of Port Jackson somewhat south of the central east of the state. The oval-shaped area which extends from about Broken Bay (Hawkesbury river estuary) on the north to a little beyond Port Hacking on the south, and from the coast east of Sydney about 40 mi. inland (near Glenbrook) forms the lower part of a geological and tectonic basin which is disposed fairly symmetrically about the line Botany bay-Penrith.

The Sydney basin is enclosed on three sides by flattish highlands which are deeply dissected and seamed with gorges by streams which now, for the most part, form part of the Hawkesbury system but which formerly had different (westward and northwestward) courses and were dislocated by the late (Tertiary?) uplift which raised the plateaus. On the seaward side, also, recent earth movements have resulted in the drowning of river valleys and created spacious inlets—Port Hacking, Botany bay, Port Jackson, Broken bay—but there also the basin-edge structure is apparent in the upstanding cliffs which form an outer rampart along the coast and give rise, at the entrance of Port Jackson, to the famous Sydney Heads, great sandstone cliffs which admit between them a deep (80 ft. low water) sea passage of a minimum breadth of $\frac{3}{4}$ mi.

The Sydney basin is one of the largest coastal lowlands of the state, but its lack of easy land communications makes the presence and growth of Sydney seem somewhat surprising. The reasons are partly physical but more historical: the superiority of the deep and sheltered harbour, defensible yet easily accessible from the sea, gave it an advantage over the shallower and more open Botany bay and the semisilted Port Hacking, and when Gov. Arthur Phillip, in 1788, moved the early settlement from Botany bay, he chose the small deep-water cove at the head of which stands Circular Quay, but where was then a fresh-running stream (Tank stream) later obliterated.

Port Jackson, sheltered from the southerly gales, covers an area of 21 sq.mi. and has a highly embayed coastline—a succession of romantic low bluffs and coves, still often densely wooded, giving a total shore line of 152 mi. It opens a way into the heart of the lowlands and upon its southern and lower shores (elevation 100 ft.) the original settlement grew. For some time it was, from the point of view of its founders, not only "the state," but "all Australia," and from it emanated, and upon it centred, much of the energy and initiative which built up the growing colony. Hence its triumph over physical obstacles, for the roads and the railways have had to cross the highlands at one of their most difficult sections, and, outside the basin, and apart from a few special areas (mining centres, and the tourist resorts at Katoomba) attracted by elevation and scenery—the barren and rugged highlands at a distance of 50 mi. are still almost unoccupied. The city expanded rapidly (pop. 1861, 95,789; 1901, 481,830; 1933, 1,235,267) until in 1961 the total metropolitan area contained 2,183,388 inhabitants. The metropolitan area includes the city proper (172,202 persons in 1961) and a group of suburbs organized into a total of 31 additional municipalities and parts of 4 others. In 1961, it covered an area of 344.7 sq.mi. and had a density of 6,334.2 persons per square mile. But this concentration of a large portion of the citizens of a vast state into what is virtually the Sydney basin is characteristic. The remarkable growth of large industrial cities, which in so many countries drained the countryside during the last half century, has characterized Australian growth from almost the beginning and without the typical agrarian preliminary stage.

However, as the city grew and industrial and commercial occupation advanced, residential areas were pushed farther out. Thus areas adjacent to but outside the existing boundaries of the metropolitan area have shown a considerable increase in population—from 124,000 persons in 1933 to 320,000 persons in 1952. The main industrial and commercial areas are situated in or in close proximity to the city of Sydney proper and in the western and southern suburbs. The northern and eastern suburbs are mainly residential, but there is also a considerable residential population in the southern and western suburbs. The climate is generally healthful and invigorating, cool and bracing with westerly winds in winter (May to September inclusive), hot and sometimes unpleasantly humid in summer. The prevailing winds from October through April are from the northeast. Mean temperatures range from 71.3° F. in summer to 55.2° F. in winter, with extremes 113.6° F. and 35.7° F. Sydney is a city of sunshine with 2,465 hr. per annum average. Rainfall is distributed throughout the year but shows an autumn and winter maximum (February-July) and averages 45 in. Sydney, besides its splendid site, has had the advantage of fine and easily procured building stone, the sandstones of Pyrmont and other local quarries. The old town had winding, narrow and relatively enclosed streets. In spite of much rebuilding, some of these persist and give the city an old-world flavour. The public buildings are, in many cases, notably fine, the two cathedrals (Anglican and Roman Catholic), the university, post office, several of the government offices, and some of the public galleries, being worthy of note. The main streets also offer excellent specimens of modern layout and substantial architecture, while many other buildings including government house, have historical interest. The city is well endowed with parks, recreation grounds and pleasure resorts generally. The 699 ac. of parks within the city boundaries include Moore park, the fine Botanic gardens, the Domain, Hyde park which commands many splendid views; in addition the Sydney Cricket ground and the Royal Agricultural society's ground where is held annually the most famous agricultural show in the state. There are 14,000 ac. of similar reserves in the municipalities, and two large national reserves: National park (34,400 ac.) 16 mi. south of Sydney around Port Hacking, and the Ku-ring-gai Chase (38,300 ac.) 15 mi. north on Broken bay —both with magnificent scenery.

The harbour of Sydney, with its coves, creeks and bays, is a favourite pleasure resort, as are also such beaches as Manly for surf bathing and water sports. Sydney has an excellent and assured water supply. In 1952 the storage reservoirs had a capacity of 124,892,000,000 gal., and the catchment area for these reservoirs covered 3,759 sq.mi. Electric trams, motor omnibuses, electric and steam railways serve the city and suburbs, and ferries ply in the harbour. The great steel-arch Sydney bridge, completed in 1932, which spans the harbour from Dawes Point (south) to Milson's Point (north), has a total length of 3,770 ft. (main arch span, 1,650 ft.; clearance for vessels passing underneath, 170 ft.), and carries a roadway 57 ft. wide, two footways, and four lines of railway. It is one of the largest steel-arch bridges in the world. The

city is, in respect of its social, educational and artistic life a leading city of the southern hemisphere. There are about 12,000 factories in the Sydney basin area (County Cumberland), most of which are in the metropolitan area. Clothing, metal, machinery (including railway engineering) industries are the most important, with food and drink preparation second. Sydney is also the chief commercial, banking, warehousing and shipping centre of the state. Upon it are centralized the lines, not only from its own basin, but from a very large part of the state. Wheat, meat, butter, fruit and many other primary products are brought to the city, from inland or by coasting steamers, for consumption or for export, but most important and most characteristic is wool. Sydney is by far the largest wool-selling centre in Australia and its sales, which begin in September and last for eight to nine months are world famous. Port Jackson offers unrivalled opportunities for harbour development.

The Maritime Services board has pursued a vigorous policy of development and improvement and has largely transformed the earlier unsatisfactory state of much of the water front. The principal wharves lie four to five miles from the Heads and close to the business centre of the city. The board controls about 60,000 ft. of commercial wharfage, about half of which is leased to shipping companies. The principal wharves are located at Woolloomooloo bay, Sydney Cove, Glebe Island, Walsh bay and Pyrmont, where the main oversea passenger terminal is situated. Glebe Island is the wheat-exporting harbour with modern appliances including an elevator of 7,500,000 bu. capacity. There are also wool, timber, coal, and other special cargo wharves and warehouses. All these are on the southern shores and do not include ferry wharves or private jetties. The islands (9) in Port Jackson are either pleasure resorts or used for special purposes, such as naval and fire-stations. There are five large graving docks in Sydney harbour, one of which is capable of accommodating the largest vessels afloat.

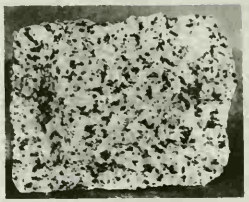
Ussher, *The Cities of Australia* (London, Toronto, 1928); *Official Year Book of N.S.W.* (Sydney, 1950–51, *et seq.*).

SYDNEY, a city of Nova Scotia, Can., is the commercial and industrial centre of Cape Breton county. Founded by Joseph Frederic DesBarres in 1783 as a haven for United Empire Loyalists, and named after the colonial secretary, it was the capital of Cape Breton Island until 1820 when the island was united with Nova Scotia. The population was increased during the early 19th century by the immigration of Scottish highlanders. Sydney is a divisional terminus of the Canadian National railways and on the south arm of the harbour are excellent facilities for ocean-going vessels. The Dominion Steel and Coal corporation is the city's chief industry. It is the centre of a large coal-mining district with an urban population exceeding 100,000. Glace Bay (*q.v.*), 14 mi. E., New Waterford, 14 mi. N.E., and Sydney Mines on the north side of the harbour are the major mining centres. North Sydney, on the northwest arm of the harbour, is the terminus of the ferry service to Port aux Basques, Nfd. Xavier Junior college (1952), an affiliate of St. Francis Xavier university, Antigonish, is located in Sydney. Across the south arm of the harbour is the Point Edward naval base. Pop. (1961) 33,617. (C. W. RD.)

SYENITE, in petrology, the group name for a class of plutonic rocks composed essentially of an alkali-feldspar and a ferromagnesian mineral. A special group of alkali-syenites is characterized by the presence of a feldspathoid mineral (nephelite, or nepheline, leucite, analcime or sodalite).

The name was first used by Pliny for the rock occurring at Syene (Assuan) on the Nile river in upper Egypt. This rock, extensively worked in ancient times for monumental structures, is a hornblende-granite with abundant quartz. A. G. Werner subsequently adopted the name for the class of rocks defined above, of which the type example is the hornblende-syenite of the Plauen'scher Grund, near Dresden, Ger. As essential constituents there occur soda orthoclase and green hornblende with subordinate amounts of oligoclase feldspar.

The texture of syenites is like that of the granites, hypidiomorphic-granular. Mineralogically these rocks differ from granites only by the absence or scarcity of quartz. The alkali-feldspars include orthoclase, perthite or albite, more rarely microcline, while the ferromagnesian mineral may be biotite, hornblende or pyroxene. In the alkali-syenites, the amphiboles or pyroxenes are frequently soda-bearing varieties. The more normal syenites are divisible into augite-, hornblende- and biotite-syenites according to their prevalent dark-coloured mineral, but syenites are also divisible, as in the case of granites, into potash and soda syenites, according to the type of alkali-feldspar. The accessory constituents include sphene, apatite, zircon, magnetite and pyrites. Syenites are by no means common and are not of equal importance with granites and diorites from a geological standpoint.



B. M. SHAUB

HORNBLENDE-SYENITE FROM CUTTINGSVILLE, VT. THE BLACK GRAINS ARE HORNBLENDE, LIGHT ONES ARE FELDSPAR

Among the potash syenites are classed the original hornblende-syenite (Plauen) and the hornblende-syenite of Biella, Piedmont, Italy, of which analyses are given below.

The rocks known as nordmarkite and pulaskite are classed among the soda syenites. Nordmarkite originally described from the Oslo region (Norway) is built up of pink microperthite and subordinate aegirine and arfvedsonite together with some quartz, while the pulaskite syenites, first described from the Fourche mountains, Ark., consist of soda-orthoclase and alkali-hornblende together with some biotite. Rocks transitional between syenites and diorites are known as monzonites (*q.v.*).

The following analyses show the chemical composition of a few of the principal types of syenite. They are characterized by a moderate amount of silica, relatively high alkalis and alumina, while lime and magnesia are more variable, but never in great amount.

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	Na_2O	K_2O
1	60.52	16.65	2.97	2.15	2.32	4.73	4.43	4.39
2	59.37	17.92	6.77	2.02	1.83	4.16	1.24	6.68
3	59.88	17.87	2.67	1.50	1.04	2.01	7.96	5.69
4	58.97	16.33	2.72	4.14	2.72	4.29	4.10	4.54

1. Hornblende-syenite, Plauen'scher Grund, Dresden, Ger.
2. Hornblende-syenite, Biella, Piedmont, Italy.
3. Nordmarkite, Oslo, Nor.
4. Syenite (mean of 12 analyses). (C. E. T.)

SYKES, SIR MARK, 6TH BARONET (1879–1919), English traveller and politician, was born on March 16, 1879, in London, the only son of Sir Tatton Sykes, 5th baronet. He was educated at Beaumont college, Windsor, at Monaco, at Brussels and at Jesus college, Cambridge. He served with the Yorkshire militia in the South African War (1902). On his return he travelled for some time in Syria, Mesopotamia and southern Kurdistan, and, after a short period (1904–05) as secretary to George Wyndham in Ireland, was appointed honorary attaché to the British embassy in Constantinople.

At the outbreak of World War I he raised a battalion of the Yorkshire regiment, but did not accompany it to France. He was sent by the government on important special missions to Bulgaria, Serbia, Russia, Mesopotamia and Syria. His special knowledge and qualifications led, in 1915, to his participation in the Anglo-French conversations in London on the Syrian question. He was an enthusiastic advocate of Arab independence. The settlement arrived at is known as the Sykes-Picot agreement. Sykes then became attached to the foreign office and was on several occasions sent on missions to Egypt. He was on friendly terms with the Arabs and designed the flag under which they marched to Damascus. In 1918, hoping to reconcile the aims of the French and the Arabs, he established himself at Aleppo, and

his diplomacy in a difficult position rendered valuable service to the government. His efforts, however, told on his health and he died in Paris of influenza on Feb. 16, 1919.

His publications include: *Through Five Turkish Provinces* (1900); *Dar-ul-Islam* (1904); *Five Mansions of the House of Othman* (1909); *The Caliph's Last Heritage* (1915).

SYLHET, a municipality and district in the Chittagong division of East Pakistan. The town is on the right bank of the Surma river, on rising ground, embowered in groves. It is on a branch of the metre gauge section of the Eastern Bengal railway, 123 mi. N.E. of Dacca. Pop. (1961) 37,740.

SYLHET DISTRICT has an area of 4,785 sq.mi. The present district comprises five-sixths of the former British Indian district of the same name, which was part of Assam until 1947. It consists of the lower valley of the Surma (Barak) river, and for the most part is a uniform plain, broken only by scattered clusters of sandy hillocks called *tilas,* and intersected by a network of rivers and drainage channels. It is a broad and densely cultivated plain. The rainfall is heavy, reaching an annual average of 159 in., of which more than 100 in. fall between June and October.

In 1961 the population was 3,489,589. The normal cultivated area is 2,400,000 ac., giving an average of nearly an acre a head but much of the district is low lying and subject to floods. Tea cultivation is a flourishing industry in the southern hills. Lime is extensively quarried; under the Mogul government Sylhet lime was a monopoly of the nawabs of Bengal. Other industries are boatbuilding and the manufacture of fine reed mats, buttons from fresh-water shells, ironwork inlaid with brass, and perfume. The perfume is exported to Turkey, Arabia and China. There are undergraduate colleges connected with Dacca university at Sylhet, Habiganj and Sunamganj.

SYLLOGISM, a two-premiss argument of any of several rather simple types distinguished by Aristotle or by those who followed in his tradition. Syllogisms are usually classified as categorical, hypothetical or disjunctive, depending upon the nature of their premisses. A categorical syllogism consists of three categorical statements (*i.e.*, statements of the forms "All *S* is *P*," "No *S* is *P*," "Some *S* is *P*," or "Some *S* is not *P*") which contain a total of at most three terms among them, each term occurring in at least two of the statements. A typical example would be:

No matadors are pirates.
Some Spaniards are matadors.
Therefore, some Spaniards are not pirates.

which is of the form (or mood) called *Ferio*:

No *M* is *P*.
Some *S* is *M*.
Therefore, some *S* is not *P*.

In the hypothetical syllogism one or both of the premisses are hypothetical in form (*i.e.*, have the form "If *p* then *q*"). Thus

If *p* then *q*.
If *q* then *r*.
Therefore, if *p* then *r*.

is one of the valid moods of the hypothetical syllogism. Similarly, a syllogism is disjunctive if one of its premisses is a disjunction. For example, every argument of the form:

Either *p* or *q*.
Not *p*.
Therefore, *q*.

is a valid disjunctive syllogism.

The term *syllogismos* ("syllogism") was used by Plato and occasionally by Aristotle simply with the sense of "argument." To this effect the latter gave his famous definition: "A syllogism is a discourse in which, certain things being posited, something else follows from them by necessity." In most cases, however, Aristotle used the term technically for the categorical syllogism. Later the meaning was extended by the Peripatetics to include hypothetical and disjunctive syllogisms. In Stoic usage the adjective *syllogisticos* ("syllogistic") was applied to any arguments of their five basic types.

See LOGIC and LOGIC, HISTORY OF. (B. MS.)

SYLT, the largest German island in the North sea, being about 36 sq.mi. in area and nearly 23 mi. long. It is, however, very narrow, being generally about half a mile in width, except in the middle, where it extends as a peninsula to the east 7 mi. across. It lies from 7 to 12 mi. from the Schleswig coast. The chief places are Keitum, Tinnum, Morsum, Rantum and Westerland. The latter is a favourite pleasure resort. During the Danish War of 1864 the island was in the hands of the Danes but was occupied by the Prussians later in that year. *See* FRISIAN ISLANDS.

SYLVESTER, JAMES JOSEPH (1814–1897), English mathematician who with his contemporary, Arthur Cayley (*q.v.*), founded the theory of algebraic invariants, was born in London on Sept. 3, 1814. In 1831 he entered St. John's college, Cambridge, where he gained high honours. In 1838 he was appointed professor of natural philosophy at University college, London. In 1841 he accepted the professorship of mathematics at the University of Virginia, but resigned after several months. Sylvester returned to London in 1845 where he obtained employment in actuarial work and took private pupils, one of whom was Florence Nightingale. In 1846 he entered the Inner Temple and in 1850 was called to the bar. About this time Sylvester and Cayley began an enthusiastic and profitable mathematical partnership. From 1855 to 1870 he was professor of mathematics at the Royal Military academy, Woolwich. It was not until 1876 that Sylvester got the first opportunity of his life commensurate with his talents, when he was appointed professor of mathematics at Johns Hopkins university, Baltimore, Md. In 1883 he returned to England to succeed Henry J. S. Smith as professor of geometry at Oxford. He died in London, March 15, 1897.

Sylvester was primarily an algebraist. With Cayley, he created the theory of algebraic forms. In the theory of numbers he did brilliant work, particularly in partitions and diophantine analysis. He worked by inspiration, and frequently it is difficult to detect a proof in what he confidently asserted. All his work is characterized by powerful imagination and inventiveness. While at Johns Hopkins, Sylvester founded (1878) the *American Journal of Mathematics,* thus contributing to the development of mathematical research in the U.S.

See Eric T. Bell, *Men of Mathematics* (1937). (E. T. B.; X.)

SYLVESTER, JOSUAH (1563–1618), English poet-translator, best known as a translator of a popular biblical epic, was born in Kent and died on Sept. 28, 1618, at Middleburg in the Low Countries, where as secretary to the Merchant Adventurers he wound up a varied career. His chief production, the *Divine Weeks and Works,* translated from the French Protestant poet Guillaume du Bartas (1544–90), appeared in sections in 1592 and complete in 1608. This epic on the Creation, the fall of man and other early parts of Genesis had high prestige in Europe generally and, in Sylvester's translation, was extremely popular in England in the first half of the 17th century. Its appeal was in its biblical matter, its reassuringly orthodox treatment of religion, nature as God's handiwork, science and cosmology, and in the grandiose, picturesque vigour of the writing—a quality only heightened in Sylvester's frequent extravagance of phrase, which Dryden, a youthful admirer, came to regard as "abominable fustian." Sylvester had some small influence on Milton and also had a share in the early development of the heroic couplet and the "poetic diction" which the Augustans were to refine.

The *Complete Works of Josuah Sylvester* were edited by A. B. Grosart in 2 vol. (1880).

SYLVIIDAE: *see* WARBLER.

SYLVITE, a mineral consisting of potassium chloride and the chief commercial source of potassium compounds, was first observed in 1823 as an incrustation on Vesuvius lava. Well-formed crystals were subsequently found in the salt deposits of Stassfurt, Ger., and Kaluszyn, Pol. It also occurs in the southern

Harz region of Germany, in the nitrate deposits of Chile and Peru and in the Permian salt basin of southeastern New Mexico and adjoining parts of Texas. Sylvite crystallizes in the cubic system with the form of cubes and cubo-octahedra and possesses perfect cleavages parallel to the faces of the cube. The composition is KCl and the crystal structure is similar to that of rock salt, NaCl. Crystals are colourless (sometimes bright blue) and transparent; the hardness is 2; specific gravity 1.99. Like salt, it is highly transparent to heat waves. The name sylvite is from the old pharmaceutical name, *sal digestivus sylvii*. (Cl. F.; X.)

SYLVIUS, FRANCISCUS (Franz de le Boë, or du Bois) (1614–1672), German physician and anatomist, called the true founder of the iatrochemical school (*see* Iatrochemistry) was born in Hanau on March 15, 1614. He studied at various universities, acquired a degree from Basel and became professor at the University of Leyden (1658), where his enthusiasm and original ideas attracted numerous students. An instance of pedagogical novelty, although not originality, was Sylvius' introduction of ward instruction in medical education.

Sylvius based his medical system upon such then recent developments in anatomy and physiology as the circulation of the blood and the recognition of the lymphatics, although still within the general framework of Galen's humoural physiology. At the same time, like his predecessor, J. B. van Helmont (*q.v.*), but omitting the mystical element so strong in the latter, he emphasized the chemical aspects of physiology. His study of salts led him to the belief that they were the result of the interaction of acids and bases, and he recognized their existence in living matter in his *Praxeos medicae idea nova* (1671–74).

According to Sylvius, digestion is a process of fermentation in which the saliva and pancreatic juice play the chief roles, the former determining digestion in the stomach and the latter directing the course of the digested food into blood or feces. The most important processes of normal and pathological life take place in the blood, and diseases are explained and treated chemically, the indications for treatment being based upon the presumed relationship between disease and drug.

In other aspects of medicine Sylvius distinguished between conglomerate and conglobate glands, and it is his name that is associated with the Sylvian aqueduct and Sylvian fissure, described in his *De spirituum animalium in cerebro cerebelloque confectione* (1660), although these structures appear to have been noted earlier by others. He also made some contribution to pediatrics through his posthumous *De morbis infantium* (1674), which, translated into English in 1682, gained favour perhaps more through its author's academic stature than through any singular importance of the contents.

Sylvius died in Leiden, Holland, Nov. 15, 1672.

(C. D. O'M.)

SYMBIOSIS is the general term for the partnerships of dissimilar organisms; it denotes simply the living together of different kinds of organisms. In this discussion three major types of symbiosis are recognized: (1) commensalism, in which food or space may be shared without evident benefit or harm to either organism or in which the benefit relation is one-sided, but without harm to the host; (2) mutualism, in which both host and guest (or the two partners) are obviously or apparently benefited and (3) parasitism, in which the host is subject to varying degrees of injury while the parasite benefits. The term symbiosis has been widely used in the restricted sense of mutualism. The broader definition corresponds both to the original definition of symbiosis by Heinrich de Bary (1879) and to modern usage. Because of the great importance of parasitism to human life and economy, this subject is dealt with separately (*see* Parasitology).

Commensalism.—Pierre van Beneden (1876) referred to a commensal as an organism that "requires from his neighbour a simple place on board his vessel, and does not partake of his provisions. The messmate does not live at the expense of his host; all he desires is a home or his friend's superfluities." The arrangement represents a level of relationship a degree removed from that in aggregations of animals about a common food supply.

The commensal relation is often between individual larger host and individual smaller guest; the host organism is unmodified, whereas the commensal guest may show great structural adaptation consonant with its habits, as in the remoras (*q.v.*) that ride attached to sharks and other fishes, or no modification other than the habit of dependence on its host. The main types of dependence shown in commensalism are for shelter, support, locomotion (*i.e.*, distribution and spread) and food supply. These may be single or variously combined. Some of the more familiar household insects associated with man illustrate several of these relations—the house cricket, the common cockroach, etc. Only when the host-guest relation is recognizably specific, a particular guest species being regularly commensal with a particular host species, is commensalism sharply defined. The shelter relation is seen in the inhabitants of the tubes of marine worms or in the insect inhabitants of field mouse nests. The support relation may involve plants sessile upon animals, as algae on turtle shell, or animals on plants, as bryozoans and hydroids on floating sargassum weed (*see* Sargasso Sea). Locomotion and food supply are combined in the remoras. Food supply is the main factor in the host of bacteria and protozoa that inhabit the gut of larger animals without apparent contribution to the digestive process of the host.

Mutualism.—Relationships in which benefits to both partners may be discerned and in which both may be radically modified in adjustment to the mutualistic relation are widespread and present diverse aspects. Mutualism may exist between plant and plant, between plant and animal and between animal and animal. The adjustments are both operational and evolutionary, and the mutualistic relation is one of the major types of co-operation in nature.

Plant and Plant.—In apparently mutualistic relations between plant and plant the degree of benefit to one or the other partner may be obscure. One of the best known of such partnerships is that between fungi and algae to form lichens (*q.v.*), the discovery of which led to the coining of the term symbiosis. The support and protection supplied by the fungus, combined with the carbohydrate synthesis of the alga, makes possible the invasion of inhospitable rock surfaces and other adverse environments by lichens.

The relation of certain fungi with the roots of higher plants (mycorhiza; *q.v.*) is extremely widespread and not, indeed, confined to the higher plants. Fungus mycelium (of various species) may form an enclosing feltlike mat around the roots of trees and other woody plants. In this case the benefit to the higher plant appears to lie in improved absorption of the food-bearing solution at the root surface. Even more intimate relations appear in the mycorhiza of orchids, in which the fungus mycelium may be essential to normal germination and development. The fungus mat may be entirely external, or the fungus may send filaments throughout the host plant. In the latter case the filaments of mycelium on the roots replace the normal root hairs.

The combination of nitrogen-fixing bacteria with leguminous plants recalls the mycorhizal relation in the obscurity of benefit to the bacteria, though in the legumes gall-like root nodules harbour the bacteria. The existence of the fixed association is the presumptive evidence of mutual benefit.

Plant and Animal.—The combination of green algae with various simple animals is made conspicuous by the resultant colouring of the animals. Various single-celled green algae, zoochlorellae, together with superficially similar yellow or brown flagellates, zooxanthellae, are regularly associated with protozoa, sponges, coelenterates, flatworms and certain other types. Zoochlorellae and zooxanthellae are regularly present in the polyps of reef corals thus, in vast total numbers and mass. In its life cycle the free-living marine flatworm *Convoluta roscoffensis* begins existence entirely free from zoochlorellae, acquires a dense intracellular population of the algae as it develops, whereupon it ceases active feeding, and finally loses the algae during senescence. In the similar association of algae with the fresh-water *Chlorohydra*

viridissimus the supply of oxygen and carbohydrate food to the host animal and of carbon dioxide and nitrogenous food to the plant was experimentally examined and largely substantiated. In *Chlorohydra*, the transmission of the zoochlorellae to the egg cell takes place directly, without an alga-free juvenile stage.

The habit of growing various fungi for food developed independently among beetles, termites and ants. The fungi grown by various species of beetles of the families Ipidae and Platypodidae in burrows in tree trunks appear to be species-specific. The leaf-cutting ants commonly extend their destructive activities to horticultural plants and have thus been the focus of much study. The fungus-growing termites of the old world quite obviously developed this habit independently of both ants and beetles. For all these insect gardeners some means of transmitting the fungus to a new nest is essential, and remarkable special apparatus exists in both beetles and ants for this purpose. The means of transmission remains to be discovered in the fungus-growing termites (*see* Social Insects).

An important mutualistic relation exists between larger animals (*i.e.*, many ruminants such as cows, goats, sheep, camels, etc.) and a series of bacteria that inhabit their alimentary tracts, for the bacteria aid in the digestion of cellulose or other refractory food materials and synthesize certain vitamins. Enormous numbers of such bacteria may be harboured in special structures such as caeca or elaborate divisions of the stomach.

Among the most interesting of the mutualistic plant-animal symbioses are those between insects and certain bacteria and fungi. In some instances the microorganisms (or symbiotes) live freely in the lumen of the alimentary tracts or in the associated caeca of their insect hosts. In other instances the symbiotes live within the tissue cells of the insect. In both instances the microorganisms appear to be highly specific and are transmitted from generation to generation by rather complicated mechanisms, usually via the eggs of the insect. In most instances the beneficial role played by the symbiotes is unknown, or only assumed; however, in many cases it has been shown that the insect cannot survive without the symbiotes and that the latter may produce certain essential vitamins or hormonelike substances. In aphids, for example, the symbiotes are believed by some to fix atmospheric nitrogen. The insect-symbiote relationship is an intimate one since usually every individual of an insect species harbours the microorganism. The intracellular symbiotes live in cells called mycetocytes which are frequently grouped into an organ or structure known as a mycetome. Some of the extracellular symbiotes occurring in the alimentary tracts of insects are known to take an active part in the digestive processes of the host (such as the bacteria found in the "fermentation pouches" of larvae of lamellicorn beetles). Certain bacteria are found in large numbers in the "gastric caeca" of higher Hemiptera. The arthropod hosts of the intracellular symbiotes occur in most of the principal orders of insects and numerous families of ticks and mites. Insects of both medical and agricultural importance are concerned, including such groups as cockroaches, lice, bedbugs, reduviid bugs, aphids, scale insects, beetles, ants and many others.

A vast series of plant-animal mutual benefit associations is supplied by the phenomenon of insect fertilization of flowers. These range from the most casual visitation of an open type of flower by a wide variety of insects, in which there may be little or no modification for the accomplishment of pollination, to the most strict relation of a single species of flower with a single species of insect, in which both are modified for their mutual relations. Elaborate and complex flower mechanisms, in which exactness of fit of flower parts to a specific insect, and correspondingly elaborate insect structures that function solely in cross-fertilization of the appropriate plant, have been demonstrated (*see* Pollination).

Animal and Animal.—The mutualistic relations between animal and animal may begin at the simple level of the association of birds with large herbivorous mammals, as of the North American cowbird with domestic cattle, the various tickbirds of other parts of the world and the little white cattle heron (*Bubulcus*), which associates itself with elephants and rhinoceroses as well as with domestic cattle throughout its range from North Africa to the East Indies.

A more intimate level of such mutualism between diverse types of animals is found among marine animals. Hermit crabs of various species may beset their snail-shell house with hydroids (*e.g.*, *Eupagurus constans* with *Hydractinia sodalis*) or with sea anemones (*Eupagurus prideauxi* with *Adamsia* species). Other crabs may regularly bear small sea anemones in their claws. Still others regularly have their shells grown over with various species of sponges. The advantage to the sessile animals is evidently that of supplying locomotion, the advantage to the crustacean lies in protection or camouflage. That the relation is fully mutualistic is shown especially by the hydroid *Hydractinia sodalis*, in which the basal layer that bears the polyps grows forward from the mouth of the snail shell inhabited by the hermit crab, thus making it necessary for the crab to undergo the hazard of changing its snail-shell house as it grows. The foot of the sea anemone *Adamsia* performs the same function for its host.

The cellulose-digesting mutualism of vertebrates and insects with bacteria is paralleled at the animal-animal level by a series of protozoa that accompany the bacteria in the alimentary tracts of various animals, ranging from harmless commensals to effective agents for cellulose digestion and to parasitism. The most sharply defined relation of this kind is represented by the association of primitive termites with characteristic and highly modified protozoans. It has been shown that the faunules of protozoans are characteristic of the species of termite inhabited. It is illuminating that the higher termites have accomplished the physiological step in their evolution that enables them to digest cellulose without the aid of the protozoans.

The fungus gardens of the ants are matched by the relation between ants and aphids, and certain other insects. The ants give elaborate care to the aphids from which they obtain the secreted honeydew, protecting the aphids from adverse weather and moving them from one pasture plant to another. Ants also protect aphids from certain of their natural enemies.

The series of nest inhabitants found regularly in the nests of both termites and ants exhibit the range from commensalism to a pseudomutualism of an elaborate and special form. Various families of insects, especially beetles, are associated with greatly modified ant and termite guests not found elsewhere. These forms produce special secretions, so much valued by the hosts that they treat them as normal and even favoured nest inhabitants.

The interrelations of commensalism, mutualism and parasitism are extremely complex. It is evident that parasitism may evolve from either external or internal commensalism and that mutualism may commonly develop from the various types of commensalism. In the opposite direction, it is quite possible that mutualism may arise by complete adjustment of host and guest in an originally parasitic relation. Thus symbiosis in its manifold physiological and social relations, appears as a biological phenomenon of fundamental importance.

SYMBOL, the term given to a visible object representing to the mind the semblance of something which is not shown but realized by association with it. One of the first symbols of the Saviour, the fish, was derived from an acrostic of the Greek word ἰχθύς, the component letters of which were the initials of the five words Ἰησοῦς Χριστός, Θεοῦ Υἱός, Σωτήρ, Jesus Christ, Son of God, Saviour. The ship, another early symbol, represented the Church, in which the faithful are carried over the sea of life. Other symbols are those which were represented by animals, real or fabulous, and were derived from Scripture: thus the lamb typified Christ from St. John's Gospel (i. 29 and 36), and the lion from the Book of Revelation, where (v. 5) Christ is called the "Lion of the tribe of Juda." The peacock stood for immortality;

the phoenix for the Resurrection; the dragon or the serpent for Satan; the stag for the soul thirsting for baptism. The sacred monogram Chi Rho, ☧ supposed to have been the celestial sign seen by the emperor Constantine on the eve of the defeat of Maxentius, represents the two first letters of the Greek word Χριστός which Constantine figured on his labarum, or standard, and is found on early Christian coins bearing also the favourite decoration of the Byzantine sarcophagi.

SYMBOLISTS, THE, the name given to a large but loosely connected group of French poets (many of them of foreign extraction) writing in the 1880's. The term *décadent* was often used as an alternative, especially of the extreme manifestations of the movement. In 1888 the critic Brunetière suggested that the history of French poetry from the 17th century could be plotted in three phases, the architectural, the pictorial and the musical. Bearing this programme in mind and taking as examples from his own literature Dryden's *Ode to Mistress Anne Killigrew,* Keats's *Ode on a Grecian Urn* and Tennyson's *Claribel,* the English reader will best understand the scope and extension of the Symbolist movement. In its origin the movement was a revolt against Naturalism as being too concrete, and against Parnassianism as being too clear-cut, to satisfy young minds who had caught from E. A. Poe and Baudelaire, from Wagner, and to some extent from the Pre-Raphaelites, the "sense of the ineffable" and were seeking a medium for its expression. Their object was not to declaim, not to depict, and least of all to transcribe, but to suggest: to communicate in their lost subtlety the most intimate and evanescent tones of experience. Baudelaire himself, Banville, Gérard de Nerval and Villiers de l'Isle Adam had already been engaged in the same quest. The common stock of poetic symbolism has been accumulated to serve common uses: a private symbolism, unless it is forced into currency by a great poet, is bound to be largely unintelligible and will often be suspected at least to be nonsense. It is not surprising therefore that the French public was at first half inclined to regard the new poetry as a hoax, and on the other hand to take seriously a volume of parodies *Les Déliquescences d'Adoré Floupette* (1885) which first made it popularly familiar. But in the meantime Verlaine had entered the circle; he gave it a watchword: "Pas de couleur, rien que la nuance," and in his book *Trois Poètes Maudits* introduced the young decadents to their true masters, Rimbaud, Corbière, Mallarmé. The year 1885 may be taken as the centre of the movement; besides the three already mentioned, Rodenbach, Verhaeren and Jean Moréas had then already appeared: Laforgue, H. de Régnier and Vielé Griffin published their first volumes in 1885, and they were followed by Rémy de Gourmont in 1886, Maeterlinck in 1889, Claudel in 1890, Robert de Montesquieu in 1893. With Samain's first volume in this last year the movement may be said to rejoin the main stream. Its principal representative, in prose, had been J. K. Huysmans: as poets, Rimbaud, Verlaine and Mallarmé, still after 40 years dominant influences in French literature. It was Mallarmé who provided the symbolists with their aesthetic theory and the most accomplished models of metric style, and in the whole course of the movement his weekly conversations were probably the most effective influence at work—an influence not unfelt in England, where it coincided with the aesthetic movement and the Celtic renascence.

SYMEON, "the Great," Bulgarian tsar (? –927) succeeded his father Boris (*q.v.*) in 893, after the short intervening reign of his dissolute elder brother, Vladimir. Educated in Constantinople, Symeon was probably destined by his father for the archbishopric of Bulgaria, and at one time took monastic orders.

His dominant ambition, himself to ascend the imperial throne of Byzantium—an aspiration afterwards shared by many Bulgarian tsars—led Symeon to embark on many wars with the empire (894, 896, 913, 917, 923). He never took Constantinople, although it was more than once at his mercy; but he took for himself the title of "Tsar of all the Bulgarians" (918) and raised the archbishop of Bulgaria to the rank of a patriarch. In the Balkans he extended the power of Bulgaria over south Macedonia, south Albania and Serbia, which became his vassal; but Bulgaria's shadowy dominion north of the Danube was probably lost during his reign. Symeon was twice married, and left four sons, of whom the second, Peter, succeeded him.

SYMEON METAPHRASTES, the most renowned of the Byzantine hagiographers. The menology of Metaphrastes, who is thought to have lived in the second half of the 10th century, is a collection of lives of saints for the twelve months of the year, consisting of about 150 distinct pieces, some of which are taken bodily from older collections, while others have been subjected to a new recension (μετάφρασις). Among other works attributed (though with some uncertainty) to Symeon are a *Chronicle,* a canonical collection, some letters and poems, and other writings of less importance. The Greeks honour him as a saint on Nov. 28, and an office has been composed in his honour.

See A. Ehrhard, *Die Legendensammlung des Symeon Metaphrastes* (Rome, 1897).

SYMMACHUS, pope from 498 to 514, a native of Sardinia and apparently a convert from paganism, was in deacon's orders when he was elected as successor to Anastasius II and promptly consecrated, in the Lateran, on Nov. 22, 498. The election, however, was not unanimous: another candidate, Laurentius, having the support of a strong Byzantine party, was also consecrated, in Sta. Maria Maggiore, on the same day. A decision was obtained in favour of Symmachus from the Gothic king Theodoric; but peace was not established until 505 or 506, when Theodoric ordered the Laurentian party to surrender the churches of which they had taken possession. An important incident in the protracted controversy was the decision of the "Palmary synod" of 502, in favour of Symmachus. The dispute gave rise to a body of literature which was drawn on by later exponents of the doctrine *quod prima sedes non judicatur a quoquam* (*i.e.,* that no-one can pass judgment on the pope). Symmachus died on July 19, 514.

SYMMACHUS, QUINTUS AURELIUS (*c.* 345–410), was a brilliant representative of 4th-century paganism in Rome. He was educated in Gaul, and in 373 was pro-consul of Africa (for his official career see *C.I.L.* vi. 1699). His public dignities, which included that of pontifex maximus, his great wealth and high character, added to his reputation for eloquence, marked him out as the champion of the pagan senate against the Christian emperors. In 382 he was banished from Rome by Gratian for his protest against the removal of the statue and altar of Victory from the senate-house, and in 384, when he was prefect of the city, he addressed to Valentinian II. a letter praying for the restoration of these symbols. After this Symmachus was involved in the rebellion of Maximus, but obtained his pardon from Theodosius, and appears to have continued in public life up to his death. In 391 he was Consul ordinarius. His honesty, both in public and in private affairs, and his amiability made him very popular. As his letters do not extend beyond the year 402, he probably died soon after that date.

Of his writings we possess: (1) *Panegyrics,* written in his youth, two on Valentinian I and one on the youthful Gratian; (2) nine books of Epistles; (3) parts of *Complimentary Orations,* five from a palimpsest (also containing the *Panegyrics*), of which part is at Milan and part in the Vatican, discovered by Mai, who published the Milan fragments in 1815, the Roman in his *Scriptorum veterum nova collectio,* vol. i (1825), and the whole in 1846; (4) the *Relationes,* which contain an interesting account of public life in Rome, composed for the emperor. All earlier editions are now superseded by that of O. Seeck in *Monumenta Germaniae historica. Auctores antiquissimi* (1883), vi, 1, with introductions of his life, works and chronology.

SYMMETRIC FUNCTIONS. A symmetric function is a rational function of $x_1, x_2, \ldots, x_n$, which is unchanged when any of the $x_1, x_2, \ldots, x_n$ are interchanged. If $x_1, x_2, \ldots, x_n$ are roots of an equation $x^n+a_1 x^{n-1}+\ldots+a_n=0$, then the coefficients a_1 represent certain symmetric functions of the roots, for example, $x_1+x_2+\ldots+x_n=-a_1$, $(-1)^n x_1 x_2 \ldots x_n=a_n$. This type of function occurs in algebra (*see* EQUATIONS, THEORY OF), group theory and statistics. (R. G. SR.)

SYMONDS, JOHN ADDINGTON (1840–1893), British

essayist and historian of the Italian Renaissance, was born at Bristol on Oct. 5, 1840. He was educated at Harrow and at Balliol college, Oxford, and was elected a fellow of Magdalen college. He died in Rome on April 19, 1893.

Of acute sensibility, he developed early symptoms of pulmonary disease and, after many journeys in search of health, finally (1877) settled at Davos Platz in the Swiss highlands, where most of his work was done, though with frequent journeys to Italy. Symonds found in literary work and in the society of his Swiss friends and neighbours relief from torturing metaphysical doubts, and his output was very large. His chief work, *The Renaissance in Italy* (7 vol., 1875–86), is rather a series of extended essays than a systematic history but has passages of both insight and eloquence. He also translated the *Sonnets* of Michelangelo and Campanella (1878), the *Autobiography* of Benvenuto Cellini (1887), and the *Memoirs* of Carlo Gozzi (1890). His *Life of Michelangelo Buonarrotti* (1892) is a work of great industry and research, but shows signs of failing powers.

Earlier he had published two series of *Studies of the Greek Poets* (1873–76), several volumes of travel sketches, and monographs on Shelley (1878), Sir Philip Sidney (1878) and Ben Jonson (1886), and on the day of his death appeared his study of Walt Whitman, with whom he had corresponded and of whom he was one of the first European admirers. His verse is of less account.

Stevenson, *Memories and Portraits* (1887), in which Symonds figures as Opalstein in "Talks and Talkers"; P. L. Babington, *Bibliography of the Writings of J. A. S.* (1925). (J. Ps.)

SYMOND'S YAT, one of the most famous view points on the River Wye, England. It stands on the River Wye 9 mi. above Monmouth and 12 mi. below Ross, on a deeply incised meander nearly 5 mi. long and 600 yd. across the neck. The peninsula forms Huntsham hill, in which there are caverns.

SYMONS, ARTHUR (1865–1945), English poet and critic, was born in Wales of Cornish parents, on Feb. 28, 1865. He was educated privately, spending much of his time in France and Italy. He was a contributor to the *Yellow Book* and in 1896 became with Aubrey Beardsley editor of the *Savoy.* Symons was an admirer of Stéphane Mallarmé, Charles Baudelaire and Paul Verlaine, and he did much to spread the ideas of the French symbolists in England. He was an acute critic and covered a wide field. His poetry belongs mainly to the *fin de siècle* in feeling. His works include: verse—*Silhouettes* (1892), *London Nights* (1895), *Amoris Victima* (1897), *Images of Good and Evil* (1900), *The Fool of the World* (1906); prose—*The Symbolist Movement in Literature* (1899), *Studies in Prose and Verse* (1904), *Spiritual Adventures* (1905), *Studies in Seven Arts* (1906), *Studies in Elizabethan Drama* (1920), *Charles Baudelaire* (1920), *Confessions,* an autobiography (1930). He also contributed a number of articles to the *Encyclopædia Britannica.*

SYMPHONIC POEM (TONE POEM, SYMPHONISCHE DICHTUNG, TONDICHTUNG, POÈME SYMPHONIQUE). A type of composition for orchestra of 19th-century origin, it is generally in one movement in contrast to the several movements of a symphony; it is a kind of program music (*q.v.*) based on a literary, pictorial or any extramusical idea which may affect both its content and form. The term program symphony denotes a symphony based on extramusical ideas—Beethoven's *Pastoral* symphony (No. 6) for example. Whether the listener should be acquainted with the composer's program or simply listen to the music as music is a debatable question; opinion generally favours a knowledge of the program by the listener.

The symphonic poem proper began with Franz Liszt. (However, some overtures of Beethoven, the "Leonore No. 2" for example, are near ancestors.) Liszt first applied the term to a series of 12 compositions, the first of which was called "Ce qu'on entend sur la montagne" ("Heard on the Mountain") (1848–49), based on a poem by Victor Hugo. Also from this series are the popular "Les Préludes" (1850) and "Hamlet" (1858). Liszt was influential in the development of new forms. A contribution to composition technique was his system of theme metamorphosis by which a single theme, through altering the rhythm, changing the tempo, etc., was made to serve the several sections of an entire composition, thus providing musical unity where the program determined the form. "Les Préludes" illustrates the technique. Liszt emphasized the poetic qualities of the theme although at times he inclined toward bombast.

The spirit of nationalism found expression in such works as Friedrich Smetana's set of six compositions, *My Country* (1874–79), of which "The Moldau" is the best known; Jean Sibelius' *Finlandia* (1899); Nicolas Rimsky-Korsakov's *Scheherazade* (1888), its four movements linked by the recurring themes associated with Scheherazade and the sultan. Descriptive ability and character delineation are illustrated in Peter Ilich Tschaikovsky's *Romeo and Juliet* (1869); poetic treatment of subject matter is found in César Franck's *Psyché* (1886–88). Camille Saint-Saëns' *Danse macabre* (1874) is descriptive but not musically involved. Richard Strauss's masterful technique of orchestration and his descriptive and narrative ability are demonstrated in such works as *Don Juan* (1888) and *Till Eulenspiegel* (1895). Extreme realism is often encountered in the Strauss works.

The first quarter of the 20th century witnessed such imaginative, expressive and varied compositions as Claude Debussy's *La Mer* (1903–05); Frederick Delius' *In a Summer Garden* (1908); Arnold Schönberg's *Pelléas and Mélisande* (1902); Charles Griffes' *The Pleasure Dome of Kubla Khan* (1919); and many more. During the second quarter of the 20th century composers generally turned their attention to more specifically musical matters.

See R. W. S. Mendl, "The Art of the Symphonic Poem," *Musical Quarterly* (July 1932); H. Ulrich, *Symphonic Music* (New York, 1952). (P. A. P.)

SYMPHONY, in music. (1) The term *συμφωνία* was used by the Greeks, first, to denote concord, in general, whether in successive or simultaneous sounds; second, in the special sense of concordant pairs of successive sounds (*i.e.*, the "perfect" interval of modern music; the 4th, 5th and octave); and third, as dealing with *ἀντιφωνον,* the concord of the octave, thus meaning the art of singing in octaves, or *magadizing,* as opposed to *ὁμοφωνία,* or singing and playing in unison. In Roman times the word appears in the general sense, which still survives in poetry, viz., as a harmonious concourse of voices and instruments. It also appears to mean a concert. In St. Luke xv, 25, it is distinguished from *χόροι* and translated as signifying "music and dancing." Polybius and others seem to use it as the name of a musical instrument.

(2) In the 17th century the term is used, like "concerto," for certain vocal compositions accompanied by instruments, *e.g.*, the *Symphoniae sacrae* of Heinrich Schütz. The modern use of the word symphony for the instrumental ritornello of a song is also found in Schütz's *Kleine geistliche Concerte.*

(3) The principal modern meaning of the word is a sonata for orchestra (*see* SONATA FORMS). The orchestral symphony originated in the operatic overture (*q.v.*), which in the middle of the 18th century began to assimilate the essentials of the sonata style. Mozart's overture to his early opera, *La Finta Giardiniera,* marks the breaking point between three-movement symphony and operatic overture, since it contains the usual first movement and slow movement, and the curtain rises with what sounds like the beginning of its third movement.

Though the sonata style is dramatic, the stiffness of its early forms did not help C. W. Gluck toward his ideal of an overture that should prepare the listener for the drama. Hence the overtures of Gluck are based on the contrast of loosely knit passages of various textures in vague forms which he learned from San Martini. These are no less evident in the symphonies of Philipp Emanuel Bach.

The differentiation between symphony and overture raised the dignity of the symphony; but the style was more essential than the form; and in Mozart's and Haydn's mature works we find the

sonata form as firmly established in the overture as in the symphony, while the styles are quite distinct. Mozart's most elaborate overture, that of *Die Zauberflöte*, could not possibly be the first movement of one of his later symphonies; nor could the finale of his *Jupiter* symphony be taken for a prelude to an opera.

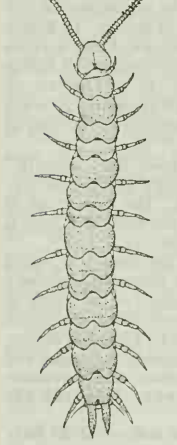
See also MUSIC; SONATA FORMS; ORCHESTRATION; OVERTURE; SCHERZO; VARIATIONS. (D. F. T.)

SYMPHORICARPOS, a genus of the honeysuckle family comprising about 15 species of deciduous shrubs, native to North America except for a single species found in China. The leaves are opposite, simple, usually entire, and without stipules. The flowers are borne on short stalks either clustered or solitary and relatively inconspicuous. The fruit is a berrylike drupe with two seeds, and constitutes the chief decorative value of the plants. Perhaps the best known species are snowberry or waxberry (*S. albus*); wolfberry, also called buckbrush (*S. occidentalis*); and Indian currant or coralberry (*S. orbiculatus*). These, as well as a few other species, are excellent ornamental shrubs for either partly shaded or open places. (J. M. BL.)

SYMPHOSIUS (SYMPOSIUS), Latin writer of riddles, who provided a model for this type of literature in the middle ages, probably lived in north Africa in the 4th or 5th century A.D. Most of his 100 riddles, which consist of three hexameters each, are about animals or objects of everyday life. The prologue states that they were composed for the Saturnalia.

There is an edition by E. Baehrens in the Teubner series, *Poetae Latini minores*, 4:364–385 (1882).

SYMPHYLA, a class of small, many-legged tracheate arthropods (myriapods), the largest representatives being slightly less than one centimetre in length. The skin of these animals is thin, soft and colourless. They live under logs, leaves and stones, where their white bodies contrast sharply with the darker soil. Although symphylids usually subsist upon decaying vegetable matter and delicate rootlets and tissues of living plants. One species in particular, *Scutigerella immaculata*, is known to do extensive damage to such crops as celery, lettuce, asparagus and beets. This form is often spoken of as the "garden centipede," although the absence of poison jaws and other basic differences widely separate it from true centipedes (*q.v.*).



FROM MICHELBACHER IN "HILGARDIA" (UNIVERSITY OF CALIFORNIA)

FIG. 1.—ADULT SYMPHYLID (SCUTIGERELLA IMMACULATA)

As in other myriapods, so-called, the head is distinct. The body is composed of 14 segments, bearing 15, or rarely 22 tergites. Twelve pairs of usually five-jointed legs are present, one pair to each of the first twelve segments. The head, which bears a Y-shaped dorsal suture like that of insects, lacks eyes and bears a pair of long, many-segmented antennae. The mouthparts include a pair of mandibles, a pair of maxillulae (paragnatha) and two pairs of maxillae of which the second pair combine to form a labium as in insects and centipedes. Only one pair of respiratory spiracles are present; these open on the head near the bases of the antennae. The paired reproductive organs open by a single pore lying between the third and fourth pairs of legs, a characteristic placing them with millipedes and pauropods in the now widely recognized group Progoneata. The females lay their eggs in clusters in the ground. As with the millipedes, the young hatch out with three pairs of legs, the rest being developed later.

The symphalids have a world-wide distribution. Because of neglect by most collectors only about 100 species have so far been recognized. Formerly, they were placed in three families, two of which have been placed with the centipedes, the family Scutigerellidae remaining. The name Symphyla refers to the intermediate position of these animals, all of which show obviously connecting characters with other groups of tracheate arthropods, especially insects.

SYNAGOGUE, a Jewish house of worship. In Hellenistic Greek, *synagoge* was the term for assembly and later for the place where the assembly gathered, corresponding to the Hebrew *Keneset* and *Bet ha-keneset*. The phrase "meeting places of God" in Ps. lxxiv, 8 is generally assumed to be a reference to synagogues (and was so translated in the Authorized Version). Talmudic literature also uses the terms "house of the people" (based on Jer. xxxix, 8) and "small sanctuary" (based on Ezekiel xi, 16) while Greek sources speak of "house of prayer" (*proseuche* or *proseukterion*) and occasionally "sabbath house." In modern times "temple" and *shul* (Yiddish, from the German *schule*) are common. United States usage often distinguishes between a temple, meaning a Reform Jewish synagogue, and a *shul*, an Orthodox Jewish house of worship.

The beginnings of the synagogue are obscure. It most probably originated during the Babylonian Exile as an institution for public worship and instruction soon after the destruction of the Temple in 586 B.C. After the return from the Babylonian Captivity, especially under Ezra and his successors, the synagogue developed side by side with the cult of the Temple in Jerusalem. Some scholars trace the origin of regular worship in the synagogue to the institution of Maamadoth, which formed part of the Temple worship; along with each of the 24 priestly divisions, certain towns would arrange for a two-week assembly of prayer and worship. The oldest dated evidence of a synagogue is the dedication of a house of worship to Ptolemy III (3rd century B.C.) inscribed on a marble slab discovered near Alexandria, Egy. Approximately 50 ancient synagogues were excavated in Palestine and the surrounding area during the 19th and 20th centuries, but they are all from the 2nd to the 6th centuries A.D. Philo and Josephus, as well as the New Testament and the early rabbinic sources,

FOTO REISEWITZ, NEUSTADT AN DER WEINSTRASSE, FRIEDRICHSTRASSE 25, GERMANY

INTERIOR OF RASHI CHAPEL, AT WORMS. THE CHAPEL, ATTACHED TO THE WORMS SYNAGOGUE, WAS RESTORED AFTER ITS DESTRUCTION IN 1938

speak of the synagogue as an institution that had been in existence from early antiquity. The literature of the 1st century also refers to numerous synagogues not only in Palestine but in Rome and Greece as well as in various cities in Egypt and Babylonia and throughout Asia Minor. Toward the end of the second commonwealth (middle of 1st century A.D.) there were synagogues wherever there was a Jewish settlement of sufficient size to support organized congregational activity. The destruction of the Temple by Titus (*c.* A.D. 70) had no adverse effect on the synagogue, which had long been a well-established and independent institution. During the centuries following the fall of Jerusalem the synagogue gained in importance, becoming the centre of the corporate life of the Jewish community.

The character of the synagogue, often termed "the child of the dispersion," represented from its inception a radical departure from that of earlier places of worship. It was not restricted to any geographic locale that presumably possessed inherent sanctity; it had no sacrificial or sacramental ritual; it did not require the intermediacy of a special priesthood. Any group of Jews, regardless of place, may establish a synagogue and share the responsibility for the conduct of its affairs. Essentially democratic, the synagogue represents a fellowship of worshipers seeking God through prayer and study.

WERNER BRAUN

PULPIT AND WOMEN'S GALLERY OF CONEGLIANO VENETO SYNAGOGUE, 1701, MOVED FROM VENICE TO JERUSALEM IN 1940

Certainly from the 1st century A.D., and probably much earlier, morning, afternoon and evening services were conducted in the synagogue daily and on the Sabbaths and festivals. These worship services consisted of the recitation of Psalms and of set prayers of praise, petition, thanksgiving and confession as well as readings from the Pentateuch, the Prophets and selections from rabbinic literature. On special occasions, particularly on the Sabbath, the service included a sermonic exposition of the scriptural lesson as well as public lectures on various aspects of the law. The facilities of the synagogue, particularly the rooms adjoining the main prayer hall, were often employed for a variety of other purposes throughout the ages. They served as the meeting place for the leaders of the community and for popular assemblies, for publication of legal notices and decrees of the secular government (during the medieval period), for funerals of its leading members and rabbis, for weddings, circumcisions and, at times, even for lodging of travelers. Above all, the facilities of the synagogue were used for the education of children. The modern synagogue provides regular public worship, a program of education for children, youth and adults and a variety of social, cultural and philanthropic activities.

There is no typical synagogue architecture; the houses of worship were and are built in the prevailing architectural style. Numerous synagogues built after World War II are among the finest examples of advanced architectural design. The only prescriptions found in the Talmud are that the synagogue be built on the heights of a city and that it have windows ("light dwells with Him," Dan. ii, 22; and of Daniel praying, "he had windows in his upper chamber open," Dan. vi, 10), but even these few requirements are only theoretical. The modern synagogue usually contains an ark where the Scrolls of the Law are kept; a light above the ark called the eternal light or perpetual lamp; two candelabra; pews for the worshipers; and a raised platform, *bimah*, from which the scriptural lesson is read and, often, services conducted. In the medieval synagogue, the *bimah* was usually located in the centre of the auditorium and a gallery was built in the back or on the sides of the auditorium for women worshipers. Also, a *mikvah*, a ritual bath, occasionally was included in the synagogue premises. Many Orthodox synagogues today retain all or several of these features.

BIBLIOGRAPHY.—For synagogue in general, *see* various articles under "Synagogue," "Liturgy," etc., in *Jewish Encyclopedia, Universal Jewish Encyclopedia,* Hastings' *Encyclopaedia of Religion and Ethics. G. Tachau, "The Architecture of the Synagogue," *American Jewish Year Book,* vol. xxviii, pp. 155–234 (1926); R. Wischnitzer, *Synagogue Architecture in the United States* (1955). (E. MI.)

SYNAGOGUE ORGANIZATIONS. Each Jewish congregation is an independent entity, governed in most cases by an elected board of directors. Nearly all describe themselves as Reform, Conservative or Orthodox (*see* JUDAISM). No precise figures on the relative strength of the three are available, but it is believed that in the United States their numbers are approximately equal.

United States.—In the past, Orthodoxy was strongest in New York city and in the Middle Atlantic and New England areas. In smaller cities of the midwest, the south and far west the Reform temple was frequently the most prominent Jewish religious institution. Conservatism centred in some of the largest Jewish communities, though it was not especially prominent in New York city. The evolution of American Jewry, however, changed this picture considerably. Thus, the movement of the Jews of New York city to the suburbs added strength to Reform and Conservatism; the growth of Los Angeles as a centre of Jewish population meant the strengthening of Conservatism and Orthodoxy in that area.

In regard to the constituency of each group, the most notable trend is the general decline in social-class differences. Many present-day Reform congregations, in contrast to those of an earlier period, include few if any persons who are members of the upper class. The constituency of Reform is now also overwhelmingly composed of persons descended from immigrants who originated in eastern Europe rather than Germany. While the Orthodox group is extremely variegated in composition, it still possesses the strongest links with the immigrant past. However, Orthodoxy increasingly utilizes American methods of organization, and in many Orthodox congregations English has replaced Yiddish as the language of common discourse.

National synagogue federations exist in the United States for each of the three groups: (1) the Union of American Hebrew Congregations for the Reform group; (2) the United Synagogue of America for the Conservative group; and (3) the Union of Orthodox Jewish Congregations of America for the Orthodox group. The Reform federation, founded in 1873, is the oldest and the best organized of the three. The Conservative federation, founded in 1913, was relatively inactive until the 1940s, becoming after that period, however, an important agency. The Union of Orthodox Jewish Congregations, although founded in 1898, has remained a loosely organized group. Most Orthodox congregations

are small in size and do not have ties with any national body. The synagogues affiliated with the Young Israel movement, however, have achieved a measure of co-ordination, and the Yeshiva University Synagogue council also has become a force in the Orthodox group.

During the 19th century some thought that all synagogues might affiliate with a single federation—hence names such as "Union of American Hebrew Congregations," or the "United Synagogue." Today, however, even those who foresee a single "American Judaism" conceive of this as a far-off development. The Synagogue Council of America, an over-all agency, is composed of both rabbinical and lay representatives from each of the three groups. It has confined its efforts to representing the common interests of Reform, Conservatism and Orthodoxy before interreligious and governmental bodies.

American Jewish congregations have typically been organized by local residents who join together, hold services, start a religious school and raise funds for a synagogue building. Initially at least it is the members themselves who shape the exact religious complexion of the congregation. They decide whether the group should affiliate with one of the national synagogue federations. However, after World War II the federations themselves became somewhat active in promoting the establishment of congregations. Substantial variations exist in each movement, and they tend to overlap. The national bodies have been generally hesitant to promulgate detailed codes of doctrine, though they publish textbooks, magazines and diverse pronouncements for the guidance of their member congregations.

In many cases the synagogue has added an extensive list of activities to its traditional function of providing a place of worship and a centre for study by male adults of the sacred Jewish texts. Congregations increasingly become "synagogue centres" and sponsor club programs, athletic activities and public lectures. They make their facilities available for a variety of Jewish and general communal purposes. Many congregations possess affiliated organizations such as sisterhoods, men's clubs and youth groups, which provide a varied program, generally with an emphasis on social activities. Sisterhoods, men's clubs and youth groups are affiliated with federations sponsored by the national bodies.

The task of providing elementary Jewish education also has become a congregational rather than a communal responsibility. An important motivation for congregational affiliation is the desire to enroll children in the religious school of the institution.

The religious life of Canadian Jewry is essentially the same as that of the United States. Canadian synagogues belong to any one of the three U.S. congregational bodies.

Great Britain.—In Great Britain, greater centralization is provided for. The largest religious body is the United Synagogue, founded in 1870 and operating in greater London (no connection with the United Synagogue of America). In contrast to U.S. practice, the property of affiliated congregations belongs to the United Synagogue. Another distinguishing feature is the office of the chief rabbi, who functions as the religious head both of the United Synagogue and of the other Ashkenazic congregations outside the United Synagogue in London and the provinces.

Since the United Synagogue and the chief rabbinate have stood for Orthodoxy, Reform and Conservative tendencies could not be accommodated within this particular framework. Non-Orthodox congregations have formed themselves into two groups, the Reform Synagogues in Great Britain and the Union of Liberal and Progressive Synagogues. Both these are congregational unions in the American sense: their constituent bodies constitute independent entities.

The provincial congregations are independent, and the non-Orthodox groups in all parts of the country are outside the traditional ecclesiastical framework; in addition, there are Orthodox congregations in the London area that do not belong to the United Synagogue. Two congregational unions serve such bodies, many of which are ultra-Orthodox congregations, or have a more recognizable link with the immigrant past than the average United Synagogue congregation. Furthermore, as in the United States, a few Sephardic congregations exist, and these stand outside the United Synagogue and the other groups, all of which follow the Ashkenazic tradition. Reform and Conservative movements have much less strength in Great Britain than they do in the United States, and English congregations carry on a much more restricted program of activity than do American congregations.

(M. Sk.)

SYNAPSE, the functional conjunction between two neurons, making conduction of nervous impulses continuous from one to the other. Synapses occur between the axon terminations of one neuron and the cell body of an adjacent cell. This type of synapse is called axosomatic. Synapses also occur between axon terminations of one neuron and the dendrites of the next, and are then termed axodendritic. Adjacent neurons may be connected by both types of synapse. The term synaptic junction is used to describe this functional and anatomical relation. (*See* Axon; Nerve; Nerve Conduction; Nervous System.) The term is also used in embryology to denote the pairing and union of the homologous chromosomes of the male and female pronuclei. This process is also named syndesis. (W. M. M.; X.)

SYNCRETISM, the act or system of blending, combining or reconciling inharmonious elements. The term is used technically in politics, as by Plutarch, of those who agree to forget dissensions and to unite in the face of common danger, as the Cretans were said to have done; in philosophy, of the efforts of Cardinal Bessarion and others in the 16th century to reconcile the philosophies of Plato and Aristotle; and in theology, of a plan to harmonize the hostile factions of the church in the 17th century, advocated by Georg Calixtus, a Lutheran professor of theology at Helmstedt. Its most frequent use, however, is in connection with the religious development of antiquity, when it denotes the tendency, especially prominent from the 2nd to the 4th centuries of the Christian era, to simplify and unify the various pagan religons. During this period, as a result of the intimate knowledge of the world's religions made possible by the gathering of every known cult of importance into the religious system of the Roman empire, belief in the identity of many deities which resembled each other, and indeed in the essential identity of all, received a special impulse. Not only were various forms of the same deity, such as, for example, Jupiter Capitolinus and Jupiter Latiaris, recognized as being really the same under different aspects, but even the gods of different nations were seen to be manifestations of a single great being. Roman Jupiter, Greek Zeus, Persian Mithras and Phrygian Attis were one. The Great Mother, Isis, Ceres, Demeter, Ops, Rhea, Tellus, were the same great mother deity under different masks (*see* Great Mother of the Gods). Venus and Cupid, Aphrodite and Adonis, the Great Mother and Attis, Astarte and Baal, Demeter and Dionysus, Isis and Serapis, were essentially the same pair. Syncretism even went so far as to blend the deities of paganism and Christianity. Christ was compared with Attis and Mithras, Isis with the Virgin Mary, etc. Isis, perhaps more than any other deity, came to be regarded as the great maternal goddess of the universe whose essence was worshiped under many different names.

Naturally, the influence of Greek philosophy was very pronounced in the growth of syncretism. Plutarch and Maximus of Tyre affirmed that the gods of the different nations were only different aspects of the same deity, a supreme intelligence and providence which ruled the world. The Neoplatonists, however, were the first school to formulate the underlying philosophy of syncretism: "There is only one real God, the divine, and the subordinate deities are nothing else than abstractions personified, or celestial bodies with spirits; the traditional gods are only demons, that is, beings intermediate between God and man. . . . All, like every other created being, are emanations from the absolute God" (Jean Réville, *La Religion à Rome sous les Sévères,* Paris, 1886). Care must be taken, however, not to place too much emphasis upon syncretism as a conscious system. The movement which it represented was not new in the 2nd century A.D. The identification of Latin with Etruscan gods in the earliest days of Rome, and then of Greek with Italian, and finally of Oriental with the Graeco-Roman, were all alike syncretistic movements, though not all con-

scious and reasoned. The ideal of the common people, who were unreflecting, as well as of philosophers who reflected, was "to grasp the religious verity, one and constant, under the multiplex forms with which legend and tradition had enveloped it" (Réville). The advent of Greek philosophy only hastened the movement by conscious and systematic effort.

(*See* PHILOSOPHY, HISTORY OF.)

Syncretism, being a movement toward monotheism, was the converse of the tendency, so prominent in the early history of Rome, to increase the number of deities by worshiping the same god under special aspects according to special activities. In the hands of the Neoplatonists it was instrumental in retarding somewhat the fall of paganism for the time, but in the end contributed to the success of Christianity by familiarizing men with the belief in one supreme deity.

See also GNOSTICISM.

See J. Réville, *La Religion à Rome sous les Sévères* (1886), especially pages 104–127, 159–174, 284–295. (G. S.)

SYNDICALISM is an anticapitalist doctrine stressing the autonomy of working groups and advocating direct industrial action to overthrow the capitalist order. Syndicalists thus differ from socialists, who advocate capturing the political state, whether by parliamentary or by revolutionary means, as a crucial step in enacting their programs. The syndicalists, like the anarchists, by whom they were influenced, conceive the state as inherently oppressive. For its control, they would substitute that of organized workers based on production units. The structure and administration of this proposed syndicalist community remain vague and utopian.

The syndicalist doctrine was first worked out by certain leaders of the French trade-union movement toward the end of the 19th century. The word *syndicalisme* means simply trade-unionism; what is known in English as syndicalism the French call *syndicalisme révolutionnaire*. The movement flourished in France chiefly between 1900 and 1914 and had a considerable influence on other countries, especially Italy, Spain and Central and South American nations.

It had also certain close resemblances to the direct action advocated in the United States at about the same time by the Industrial Workers of the World (*q.v.*). Like the French syndicalists, the I.W.W. repudiated parliamentary action; but the I.W.W. differed in favouring strong trade-union centralization rather than emphasizing the typically small working units of the French syndicalists. There was also an analogous movement in Great Britain in the early decades of the 20th century, but this movement, called guild socialism (*q.v.*), was greatly modified both by the traditional parliamentarism of the British working class and by the nonrevolutionary character of the movement's intellectual proponents. Nevertheless certain British trade-unions were permeated by syndicalist ideas between 1906 and 1914.

After World War I, syndicalism largely ceased to be a dynamic force, even in France. Its followers tended to be attracted either by revolutionary communism, especially as represented by the U.S.S.R., or by the increasing possibilities in western democracies for socioeconomic improvement through ordinary trade-union activity as well as parliamentary action. However, syndicalism remained an important residual force, at least during the interwar years, in many European countries. Left-wing trade-union agitations, usually called Trotskyite by the Communists, often resulted from old syndicalist influence. In Spain, in particular, an anarchist opposition to Communist party discipline existed in the 1930s. During this same period, the Italian fascist dictatorship of Mussolini sought to use syndicalist sentiment, in perverted form, in recruiting support for his corporate state (*q.v.*). Syndicalist overtones were also discerned in some of the support, but not in the leadership, of the British general strike of 1926. The failure of this strike, which incidentally was hardly revolutionary in its conduct, did much, especially in Britain, to turn working-class efforts toward parliamentary action instead of direct industrial action to achieve political ends.

Syndicalists often claimed that theirs was the most proletarian of all radical social theories and owed the least to middle-class theorists. This was true of its origin but hardly of its later development by Georges Sorel, whose exposition *Reflections on Violence* (1908) is the best-known syndicalist work. Sorel introduced into syndicalism the notion of social myths by which the workers could be irrationally stirred to revolutionary action. The general strike, advocacy of which the syndicalists had taken over from the anarchists, became in Sorel's hands a myth of this kind.

The syndicalist started from the assumptions common to most schools of socialist thought. He affirmed the inherent injustice of the wage system and the fundamental immorality of capitalist society, based, in his belief, on the exploitation of labour. He accepted and pushed to its logical conclusion the Marxian dogma of the class war; he therefore affirmed that solidarity of interests does not, and cannot, exist between capitalists and wage earners. From these premises he drew the usual socialist conclusion: that individual ownership of the instruments of production must be abolished and communal ownership and control substituted for it. But at this point syndicalism and socialism parted company. Whereas the socialist demanded ownership by the state and its dependent organs such as the municipalities, the syndicalist demand was typically for direct ownership and control by the workers, acting through the organizations of their own creation—the trade-unions and federations of unions.

State organization and control of industry are, in the syndicalist view, incompatible with true working-class emancipation. The state is, and must be, an instrument of class domination; it is, indeed, "the executive committee of the capitalist class." It exists to defend the interests of that class and is consequently as much the enemy of labour as capital itself. To extend its powers would be to twine the bonds of wage slavery ever more firmly about the workers' limbs.

The state is, moreover, hopelessly wedded to an uncreative bureaucracy, incapable of initiative and ignorant of industrial technique. Its control, even if it were benevolent (which the syndicalist denies it could be), would necessarily be despotic and inefficient; the spirit of routine would combine with inexperience to crush out the possibility of economic progress. Here the syndicalist endorsed the ordinary individualistic criticism of state socialism. Workers' control, exercised through the *syndicats*, would combine freedom with efficiency.

The form of social organization in which this ideal could be realized was ordinarily conceived somewhat as follows: The unit of organization would be the local *syndicat*. This would be brought into touch with other groups by means of the local *bourse du travail* ("labour exchange"), the established function of which was to act at once as an employment agency and a general centre for trade-union activities. When all the producers were thus linked together by the *bourse*, the administration of the latter would be able to estimate the economic capacities and necessities of the region, could co-ordinate production and, being in touch through other *bourses* with the industrial system as a whole, could arrange for the necessary transfer of materials and commodities, inward and outward. A species of economic federation would thus replace the structure of capitalist industry, along with which the political and administrative machinery of the state would necessarily disappear.

Two features of this utopia need to be emphasized: consumers as such were excluded from any share in industrial control, and a localized system of industry was envisaged. This latter feature was a direct reflection of economic circumstances in France; both industry and trade-unionism were much more local in range than in other and more highly developed countries. But the movement toward large-scale organization which so profoundly affected every aspect of modern economic life produced a corresponding modification in later syndicalist ideals.

Syndicalist theory starts from the idea of a class war which must be waged relentlessly till a complete social transformation has been accomplished. The essential weapon in this struggle is the power of the organized workers. As the cause of the conflict is economic it must necessarily be fought out in the economic sphere. Syndicalist congresses thus persistently repudiated political action and pinned their faith to a general strike as the grand instrument

of social revolution. This reliance upon industrial or direct methods of action flows necessarily from the fundamental notions of syndicalism as to the nature of the state, and also from strictly practical considerations.

Outside the mine or factory, working men hold divergent religious or political opinions which make effective mass action difficult, if not impossible. Inside, the nature of their employment gives them a sense of solidarity which overrides other differences and bands them together in the *syndicat* for common defense. To persuade them to pass from the defensive to the offensive is the syndicalist's task, and in the accomplishment of this, political labels and controversies would be a hindrance. The strike, therefore, is the characteristic syndicalist weapon. However limited in its scope and object, it is an educative experience. Successful, it inspires the workers with a sense of power; unsuccessful, it impresses upon them the servility of their lot and the necessity for better organization and wider aims. Thus, every strike is a preparation for the revolutionary day when the workers, or a fighting minority of them (for syndicalism repudiates as bourgeois the dogma of the sacredness of majority rule), shall seize the instruments of production by an expropriatory general strike. In the meantime, they are working out from day to day, in the ordinary course of their employment, the ethics and the jurisprudence of the new social order.

The syndicalist idea, as understood in France, may be said to have developed out of the strong anarchist and antiparliamentary traditions of the French working class, and to have been much influenced by the teachings of P. J. Proudhon and, on another side, by Louis Auguste Blanqui. A French delegate to the congress of the International Working Men's association (known as the first international) held at Basel in 1869, for instance, prophesied that "the grouping of different trades in the city will form the commune of the future" when "government will be replaced by federated councils of *syndicats* and by a committee of their respective delegates regulating the relations of labour—this taking the place of politics."

These tendencies manifested themselves with increasing strength during the 1890s in the two main labour organizations of the period—the Confédération Générale du Travail (or C.G.T.) and the Fédération des Bourses du Travail. The secretary of this latter organization, Fernand Pelloutier, did more perhaps than any other individual in his day to work out the characteristic doctrines of syndicalism and to spread them among his fellow workers. When these two bodies joined forces in 1902, trade-unionism in general and syndicalism in particular received an immense accession of strength; and the syndicalist doctrine subsequently remained —in spite of the efforts of political socialists to capture the *syndicats* for their own purposes—the characteristic expression of French revolutionary idealism, at least until 1914. *See* also Anarchism; Communism; General Strike; Guild Socialism; Industrial Workers of the World, The; Sabotage; and Socialism.

SYNECDOCHE (Gr. *synekdoche*, "a receiving together"), a figure of speech in which a part stands for the whole, or the reverse. Examples: "bench," law court; "hand," a worker, as in "hired hand"; "ABC's," alphabet. *See* Figures of Speech: *Figures of Relationship.* (G. W. A.)

SYNESIUS (*c.* 370 or earlier–*c.* 414), bishop of Ptolemais in the Libyan Pentapolis, was born at Cyrene of wealthy parents who claimed descent from Spartan kings.

His extant works, written in Greek, are: (1) a speech before Arcadius, *De regno;* (2) *Dio, sive de suo ipsius instituto;* (3) *Encomium calvitii*, a comic defense of baldness; (4) *De providentia;* (5) *De insomniis* (on dreams); (6) *157 Epistolae;* (7) *12 Hymni;* and several homilies and occasional speeches.

Fitz-Gerald, *The Essays and Hymns of Synesius of Cyrene*, 2 vol. (London, 1930), and *The Letters of Synesius of Cyrene* (1926). *See* also C. Lacombrade, *Synésios de Cyrène* (Paris, 1951).

SYNGE, JOHN MILLINGTON (1871–1909), Irish dramatist, was born at Rathfarnham near Dublin, April 16, 1871. Educated at Trinity college, Dublin, he traveled for some years on the continent, spending much of his time in Paris. He returned in 1898 to the Aran Isles. There he wrote a number of sketches dealing with the life of the islanders, which were later collected in *The Aran Islands* (1907). In these and other sketches of the same period he had not quite shaken off the obsession of stylism, and still had a wish "to do for the west of Ireland what Pierre Loti had done for the Bretons." Gradually, however, Ireland took hold of him, and turning to the dramatization of incidents in the life he now knew intimately, he began to elaborate, partly from his notebooks and partly from the writings of Lady Gregory and Douglas Hyde, that richly imaginative Anglo-Irish dialect which he used with such complete success. When, in 1904, he became a director of the newly opened Abbey theatre, Dublin, he had already produced two one-act plays, *The Shadow of the Glen* (1903) and *Riders to the Sea* (1904), published in one volume (1905). *The Well of the Saints,* a beautiful three-act play produced in 1905, was regarded by some as an affront to Irish morals, and when *The Playboy of the Western World* appeared in Jan. 1907, it was interrupted every night for a week by an organized disturbance. When the real merits of the play became known, it contributed largely to the fame of the Abbey theatre. Time has shown how deeply Synge penetrated into the soul of the Irish peasant. The richness of the dialogue and the suggestion which it conveys of a permanent human enigma combine to make it a masterpiece. Synge's latest volumes were a collection of his poetical works entitled *Poems and Translations* (1909), and another play, *Deirdre of the Sorrows* (1910) which he all but completed before his death. Synge's greatest work is probably *The Playboy*, though some critics give pride of place to *Deirdre.* Synge died in Dublin March 24, 1909.

Masefield, *John M. Synge: A Few Personal Recollections, with Biographical Notes* (1915); J. Thorning, *J. M. Synge* (1921).

SYNGE, RICHARD LAURENCE MILLINGTON (1914–), British biochemist, was awarded the 1952 Nobel prize for chemistry jointly with Archer John Porter Martin (*q.v.*) for their method of identifying and separating chemical elements by chromatography. He was born on Oct. 28, 1914, at Liverpool and educated at Winchester college and Trinity college, Cambridge. At Cambridge and in the Wool Industries Research association's laboratories at Leeds he collaborated in chemical research with Martin. In 1943 he was appointed to the Lister Institute of Preventive Medicine, London, and from 1948 he worked at the Rowett Research institute, Bucksburn, Aberdeenshire. He was elected fellow of the Royal society in 1950. Partition chromatography, devised by Martin and Synge, effected the partition of a substance between two liquids by very simple means instead of by a series of intricate chemical operations, and it became so widely used in chemical, biological and medical research as to constitute almost a new scientific tool. In 1951 Synge, with four other scientists, formed a "science for peace" committee, and supported the "People's Congress for Peace" (Vienna, 1952). (D. McK.)

SYNOPTIC GOSPELS: *see* Gospels.

SYNOPTIC WEATHER CHART, a term used peculiarly in meteorology for maps of any large or small portion of the globe, on which are plotted weather observations taken at various points over the area represented and at approximately the same time. In addition the data on the map are usually analyzed by means of conventional symbols, isolines and shadings (*see* Weather Forecasting). The expression weather map or weather chart is essentially synonymous with synoptic chart. The adjective synoptic implies a brief or condensed means of presenting a combined or general view of something; but in meteorological parlance the word came to have the connotation of synchronous because of the

fact that according to most schools of meteorology only synchronous weather observations lend themselves to rational analysis of maps that are to be used for the purpose of preparing forecasts. The notable exception is in the U.S.S.R. where the official weather maps are not based on entirely synchronous observations but on observations made at the same local sun time.

Synoptic charts are constructed in various forms according to their purpose and the kind of data plotted on them. The basic chart for the use of forecasters is that which shows the synchronous observations at sea level or surface stations over a more or less extended area, generally at least a large part of a continent and often a whole hemisphere. For each weather station whose observations are taken at internationally standardized synoptic hours—one to four times a day—and received by radio or telegraph at the forecast offices, there are plotted in a model grouping around the circle representing the station on the map the values of or symbolic indications of a number of weather elements. For all stations at least the barometric pressure (usually reduced to sea level), the air temperature, the present weather, the wind direction and speed or force, and the sky cover will be reported. In some countries many stations also give visibility, dew point or relative humidity, forms, amounts and movements of clouds at different levels, net amount of pressure change during the last three hours, the characteristics or the tendency in the pressure during the last three hours, and the amount of precipitation after the last observation. In case of ship reports the water temperature, state of sea, position and motion of ship are also reported.

An innumerable variety of charts could be constructed from such reports, but in practice only a few are made in addition to the standard charts containing the plotting and analysis of the complete surface reports; *e.g.*, charts to show the change in pressure and the change in temperature since the previous chart or in the last 12 hr. or 24 hr. are often made. The analysis of the basic surface chart consists usually of isobars (*q.v.*), fronts (*q.v.*), and air mass (*q.v.*) designations, and shadings or symbols to show where precipitation and fog are present.

Such maps are two-dimensional. To obtain a three-dimensional synchronous view of the atmosphere, it is customary, in regions where upper-air soundings are regularly made, to construct synoptic charts for several levels in the free atmosphere. Plotted on them, at the appropriate points where soundings are reported, are the values of the elements given by the soundings at that level, usually only pressure, temperature, humidity and wind. The levels selected for upper-air charts may be surfaces of constant height, constant pressure or constant entropy. Constant-height surfaces of 5,000 ft., 10,000 ft. and 20,000 ft. mean sea level have been much used, but during the 1930s and the World War II years, after some experimentation with isentropic charts (*q.v.*), nearly all weather services gradually came to prefer constant-pressure charts; by 1945 they became practically internationally standard.

The World Meteorological organization recommended that data for the following surfaces be evaluated from the soundings and broadcast: 1,000, 850, 700, 500, 300 and 200 millibars; and that analysis of the 700- and 500-millibar surfaces be made as a minimum. After World War II transmittal of sea-level and upper-air synoptic charts by means of facsimile (both telegraphic and radio) was developed, in the United States particularly.

With the advent of jet aircraft, analysis of much higher levels in the atmosphere was required. In this connection some forecasters draw lines of equal wind speed (isotachs, isokinetics) on the constant-pressure charts for 500-, 300-, 200-millibar and even higher surfaces, and charts showing the topography of the tropopause are prepared.

For tropical regions isobaric and constant-pressure charts have not proved very helpful for forecasting, and experiments indicated that streamline charts would be more successful, though the technique is difficult and weather reporting stations were still too sparse over most of the tropics in the 1950s.

In addition to the various types of charts already mentioned, which might be called the basic ones, it is customary in the larger forecast centres to prepare many auxiliary charts such as those showing the changes in height of a pressure surface with time, and those for the thickness and temperature of the layers between a lower and a higher constant-pressure surface. Some of the systems of analysis and forecasting under trial in the 1950s involved the preparation of many charts of an intermediate character representing the step-by-step computation of derived rather than observed factors; *e.g.*, in vorticity analysis and in some methods of numerical prediction.

Finally, there are the prognostic charts which represent the forecast patterns of pressure, height of pressure surfaces, or other elements (temperature, wind, etc.), for some future time.

Thus the total number of charts constructed in a large forecast central may amount to hundreds per day, and consume the services of a large staff working in shifts around the clock.

In connection with forecasting for longer periods of time than one or two days, it is desirable or necessary to construct mean synoptic charts which show averages of the elements over five days, a week, a month or more.

Over much of the northern hemisphere synoptic observations collected immediately by wire and radio permit maps to be made one, two, three or four times a day as desired; in some countries maps can even be made for every hour. The maps can be plotted and analyzed within two to six hours after the observations are made. Upper-air data are available only once or twice a day, however. Large areas of the oceans, and particularly of the polar regions and southern hemisphere, have few observing stations or ships and hence cannot be synoptically charted in the detail required by weather forecasters. Methods of extrapolation of soundings or map patterns to heights above those reached by many of the soundings have been found expedient under certain conditions.

Synoptic charts are published daily by the leading national weather services. A remarkable series of historical weather maps for the northern hemisphere, one a day from Jan. 1, 1899, to June 30, 1939, compiled and analyzed by a uniform technique, were published by the U.S. government (weather bureau) during World War II and were resumed in 1946. The earliest weather charts were made well before 1835 by collecting synchronous weather reports by mail. The first telegraphic collection of synoptic reports and mapping thereof for forecasting was accomplished by Urbain J. J. Leverrier following the Crimean War. From about 1870 the leading nations have published charts each day along with the official forecasts. Simplified sea-level weather charts are published daily in many newspapers, posted in public places and discussed on television programs.

For the principles of analysis and use of synoptic charts in forecasting *see* AIR MASS; FRONTS; ISALLOBAR; ISENTROPIC CHART; ISOBAR; WEATHER FORECASTING.

SYRA (SYROS), a Greek island in Cyclades *nomos* (department). Pop. (1961) 19,570; area 34 sq.mi. Its prehistoric importance is attested by Aegean antiquities. Once remarkably fertile, the destruction of its forests left it a brown, barren rock, with scanty aromatic scrub, pastured by sheep and goats. In the 19th century Syra became the commercial centre of the archipelago.

Hermopolis (Hermoupolis), the chief town (pop. [1961] 14,402), on the east coast, is the residence of the nomarch of the Cyclades and the seat of the central law courts. Old Syra, on a hill behind the port town, was built by the Capuchins, who in the middle ages chose Syra as a mission headquarters. On the outbreak of the War of Greek Independence about 40,000 refugees from Chios (Khios) rallied at Syra under the protection of the French until Greek freedom was achieved.

SYRACUSE, a city of Sicily (Gr. Συράκουσαι; Lat. *Syracusae,* Ital. *Siracusa*), the capital of a province of the same name, is a port on the Ionian sea. The city is situated on the east coast of the island, 54 mi. by rail S.E. of Catania, and about 32 mi. direct.

The estimated population (1957) was 78,488 (commune).

Syracuse was the chief Greek city of ancient Sicily, and one

of the earliest Greek settlements in the island. It was founded from Corinth, and Thucydides, who gives the date as the year after the foundation of Naxos (*i.e.*, 734 B.C.), mentions that the leader Archias expelled the Sicel inhabitants from Ortygia. (*See* under SICILY.) Their presence there was definitely proved by the discovery of traces of huts and of a rock-cut tomb of the beginning of the second Sicel period on Ortygia, while similar tombs may be seen both on the north and south edges of the terrace of Epipolae, and on the peninsula of Plemmyrium. (For this and other prehistoric sites in the neighbourhood of Syracuse *see* SICILY, *Archaeology*.)

Till the beginning of the 5th century B.C. our notices of Syracuse history are fragmentary, and we do not even know when the mole connecting the island with the mainland was constructed. In its external development Syracuse differed somewhat from other Sicilian cities. Although it lagged in early times behind both Gela and Acragas (Agrigentum), it very soon began to aim at a combination of land and sea power. In 663 it founded the settlement of Acrae, in 643 Casmenae, and in 598 Camarina, of which the first was unusually far inland. The three together secured for Syracuse a continuous dominion to the south-east coast. They were not strictly colonies but outposts; Camarina indeed was destroyed after a revolt against the ruling city.

Gelon and Hieron.—Hippocrates, tyrant of Gela (492–485), threatened the independence of Syracuse as well as of other cities, and it was saved only by the joint intervention of Corinth and Corcyra and by the cession of the vacant territory of Camarina. In 485 the *Gamoroi*, or landowners (*i.e.*, the descendants of the original settlers, who formed an aristocratic body), who had been expelled by the Demos and the Sicel serfs and had taken refuge at Casmenae, craved help of Gelon, the successor of Hippocrates, who took possession of Syracuse, without opposition, and made it the seat of his power. He gave citizenship both to mercenaries and to settlers from Greece and added to the population the inhabitants of other cities conquered by him, so that Syracuse became a city of mixed population in which the new citizens had the advantage. He then extended the city by including within the fortifications the low ground (or at any rate the western portion of the low ground) between Upper Achradina and the island and making the agora there; at the same time (probably) he was able to shift the position of the crossing to the island by making a new isthmus in the position of the present one, the old mole being broken through so as to afford an outlet from the Little Harbour on the east. The island thus became the inner city, the stronghold of the ruler. Gelon's general rule was mild, and he won fame as the champion of Hellas by his great victory over the Carthaginians at Himera. He is said to have been greeted as king; but he does not seem to have taken the title in any formal way.

Gelon's brother and successor, Hieron (478–467), kept up the power of the city and won himself a name by his encouragement of poets, especially Aeschylus and Simonides, and philosophers, while his Pythian and Olympian victories made him the special subject of the songs of Pindar and Bacchylides. But in his internal government he was suspicious, greedy and cruel. After family disputes the power passed to his brother Thrasybulus, who was driven out next year by a general rising. Syracuse thus became a democratic commonwealth. Renewed freedom was celebrated by a colossal statue of Zeus Eleutherius and by a yearly feast in his honour. But when the mercenaries and other new settlers were shut out from office new struggles arose. The mercenaries, as in the last rising, held Ortygia and Achradina. The people now walled in the suburb of Tyche to the west of Achradina. The mercenaries were at last got rid of in 461. Although we hear of attempts to seize the tyranny and of an institution called *petalism*, like the Athenian ostracism, designed to guard against such dangers, popular government was not seriously threatened for more than 50 years. The part of Syracuse in general Sicilian affairs has been traced in the article SICILY (*q.v.*). We hear of a naval expedition to the Etruscan coast and Corsica about 453 B.C. and of the great military and naval preparations of Syracuse in 439.

The Athenian Siege.—The Athenian siege (415–413) is of the deepest importance for the topography of Syracuse. (The chief authorities for the siege are Thucydides [bks. vi. and vii.], Diodorus [bk. xiii.] and Plutarch, *Nicias*.) Through the whole siege there was a treasonable party within the city, which kept up a correspondence with the besiegers. When the Athenian fleet under Nicias, Alcibiades and Lamachus was at Rhegium in Italy, Athens had the prize within her grasp, and she lost it wholly through the persistent dilatoriness and blundering of Nicias. It was at his advice that the summer and autumn of 415 were frittered away and the siege not begun till the spring of 414. By that time the Syracusans had built a wall from north to south across Epipolae, taking in Tyche and Temenites, so as to screen them from attack on the side of Epipolae on the north-west. They did not, however, occupy Euryelus, at the western extremity of the high ground of Epipolae, and this omission allowed the Athenians to obtain possession of the whole plateau and to begin the investment of the city. The Syracusans then carried a counterwork up the slope of Epipolae, which, if completed, would cut in two the Athenian lines and frustrate the blockade. At this point Nicias showed considerable military skill. The Syracusans' work was destroyed by a prompt and well-executed attack; and a second counterwork carried across marshy ground some distance to the south of Epipolae and near to the Great Harbour was also demolished after a sharp action, in which Lamachus fell, an irretrievable loss. However, the blockade on the land side was now almost complete, and the Athenian fleet had at the same time entered the Great Harbour. The citizens began to think of surrender, and Nicias was so confident that he neglected to push his advantages. He left a gap to the north of the circular fort which formed the centre of the Athenian lines, the point where Epipolae slopes down to the sea, and he omitted to occupy Euryelus. He made a final and irretrievable blunder in letting the Spartan Gylippus first land in Sicily and then march at the head of a small army, across the island, and enter Syracuse by way of Epipolae, past Euryelus. Just before his arrival a few ships from Corinth had made their way into the harbour with the news that a great fleet was already on its way to the relief of the city. The tables were now completely turned. The military skill of Gylippus enabled the Syracusan militia to meet the Athenian troops on equal terms, to wrest from them their fortified position on Plemmyrium, which Nicias had occupied as a naval station shortly after Gylippus's arrival, and thus to drive them to keep their ships on the low beach between their double walls, to take Labdalum, an Athenian fort on the northern edge of Epipolae, and make a third counterwork right along Epipolae in a westerly direction, to the north of the circular fort. The Athenians were thus reduced to such a plight that, as Nicias said in his despatch towards the close of 414, they were themselves besieged rather than besieging. The naval preparations of the Syracusans, under the advice of Hermocrates, had led them, too, to confidence in their powers of giving battle to the Athenian fleet. In the first sea-fight, which took place simultaneously with the capture of Plemmyrium, they had been unsuccessful; but in the spring of 413 they actually won a victory over the Athenians in their own element.

On the very next day, however, a second Athenian fleet arrived under Demosthenes and Eurymedon, with 73 ships of war and a large force of heavy infantry and light troops. Demosthenes decided at once to make a grand attack on Epipolae, with a view to recovering the Athenian blockading lines and driving the Syracusans back within the city walls. The assault was made by night by way of Euryelus under the uncertain light of the moon, and this circumstance turned what was very nearly a successful surprise into a ruinous defeat. The army was now thoroughly out of heart and Demosthenes was for at once breaking up the camp, embarking the troops, and sailing back to Athens. But Nicias could not bring himself to face the Athenian people at home, nor could he be prevailed on to retire promptly to some position on the coast, such as Catania or Thapsus. He dallied till the end of August, many weeks after the defeat, when the coming of Syracusan reinforcements decided him to depart; but

on Aug. 27 was an eclipse of the moon, on the strength of which he insisted on a delay of almost another month. The Syracusans now blocked the mouth of the Great Harbour, and the Athenian fleet, after a frantic effort to break out and a desperate conflict, was utterly defeated and half destroyed. The broken and demoralized army, its ranks thinned by fever and sickness, at last began its hopeless retreat, attempting to reach Catania by a circuitous route; but, harassed by the numerous Syracusan cavalry and darters, after a few days of dreadful suffering it was forced to lay down its arms. The Syracusans sullied the glory of their triumph by putting Nicias and Demosthenes to death.

Dionysius I.—Her great deliverance and victory naturally stirred up the energies of Syracuse at home and abroad. Syracusan and Selinuntine ships under Hermocrates now play a distinguished part in the warfare between Sparta and Athens on the coast of Asia. Under the influence of Diocles the constitution became a still more confirmed democracy, some at least of the magistracies being filled by lot. Diocles appears also as the author of a code of laws of great strictness. Under these influences Hermocrates was banished in 409. In 407 he was slain in an attempt to enter the city, and with him was wounded Dionysius, son of another Hermocrates and an adherent of the aristocratic party, but soon afterwards a demagogue, though supported by some men of rank, among them the historian Philistus. By accusing the generals engaged at Acragas in the war against Carthage, by obtaining the restoration of exiles, by high-handed proceedings at Gela, he secured his own election as sole general with special powers. He next procured from a military assembly at Leontini a vote of a bodyguard; he hired mercenaries and in 406–405 came back to Syracuse as tyrant of the city. Dionysius kept his power till his death 38 years later (367). But it was well-nigh overthrown before he had fully grasped it. After his defeat before Gela (*see* SICILY) his enemies in the army reached Syracuse before him, plundered his house, and horribly maltreated his wife. He came and took his vengeance, slaying and driving out his enemies, who established themselves at Aetna. In 397 Syracuse had to stand a siege from the Carthaginians under Himilco, who took up his quarters at the Olympieum, but his troops in the marshes below suffered from pestilence, and a masterly combined attack by land and sea by Dionysius ended in his utter defeat. Dionysius, however, allowed him to depart without further pressing his advantage. This revolution and the peace with the Carthaginians confirmed Dionysius in the possession of Syracuse, and left it the one great Hellenic city of Sicily, which, however enslaved at home, was at least independent of the barbarian. Dionysius was able, like Gelon, though with less success and less honour, to take up the rôle of the champion of Hellas.

During the long tyranny of Dionysius the city grew greatly in size, population and grandeur. Syracuse absorbed the population of Gela, Camarina and Acragas, and received large accessions from some of the Greek cities of southern Italy, from Hipponium on its west and Caulonia on its east coast, both of which Dionysius captured in 389 B.C. There had also been an influx of free citizens from Rhegium. Dionysius largely extended the fortifications of Syracuse. The island (Ortygia) had been provided with its own defences, converted, in fact, into a separate stronghold. Dionysius, to make himself perfectly safe, drove out a number of the old inhabitants and turned the place into a barracks, he himself living in the citadel. Profiting by the experience gained during the Athenian siege, he included in his new lines the whole plateau of Epipolae, with a strong fortress at Euryelus, its apex on the west; the length of the outer lines (excluding the fortifications of the island) is about 12m. Syracuse was now the most splendid and the best fortified of all Greek cities. Its naval power, too, was vastly increased; the docks were enlarged, and 200 new warships were built. The fleet of Dionysius was the most powerful in the Mediterranean. It was doubtless fear and hatred of Carthage, from which city the Greeks of Sicily had suffered so much, that urged the Syracusans to acquiesce in the enormous expenditure which they must have incurred under the rule of Dionysius. Much, too, was done for the beauty of the city as well as for its strength and defence. Several new temples were built, and gymnasia erected outside the walls.

Dionysius' Successors.—Under his son, the younger Dionysius—an easy, good-natured, unpractical man—a reaction set in amongst the restless citizens of Syracuse. His uncle, Dion, was for a time the trusted political adviser of his nephew Dionysius II. Dion's idea seems to have been to make Dionysius something like a constitutional sovereign, and with this view he brought him into contact with Plato. But Dionysius had Philistus and others about him, who were opposed to any kind of liberal reform, and the result was the banishment of Dion from Syracuse as a dangerous innovator. Ten years afterwards, in 357, the exile entered Achradina a victor. A siege and blockade followed, till Dion made himself finally master of the mainland city. Ortygia, provisions failing, was also soon surrendered. Dion's rule lasted only three years, for he perished in 354 by the hand of an assassin.

Of what took place in Syracuse during the next ten years we know but little. The younger Dionysius came back and from his island fortress again oppressed the citizens. Sicily, too, was again menaced by Carthage. Syracuse, in its extremity, asked help from the mother-city, Corinth; and Timoleon (*q.v.*) delivered Syracuse from the younger Dionysius and from Hicetas, who held the rest of Syracuse, and won a decisive triumph over Carthage and the safe possession of Sicily west of the river Halycus, the largest portion of the island. From 343 to 337 he was supreme at Syracuse, with the hearty good will of the citizens. Syracuse, with an influx of a multitude of new colonists from Greece and from towns of Sicily and Italy, once more became a prosperous city. Timoleon, having accomplished his work, accepted the position of a private citizen. After his death (337) a splendid monument, with porticoes and gymnasia surrounding it, known as the Timoleonteum, was raised to his honour.

In the interval of 20 years between the death of Timoleon and the rise of Agathocles (*q.v.*) to power another revolution at Syracuse transferred the government to an oligarchy of 600 leading citizens. It was shortly after this revolution, in 317, that Agathocles, with a body of mercenaries from Campania and a host of exiles from the Greek cities, backed up by the Carthaginian Hamilcar, became tyrant of the city, and the senate and the heads of the oligarchical party were massacred wholesale, while a unanimous vote of the people gave him absolute control over the fortunes of Syracuse. His wars in Sicily and Africa left him time to do something for the relief of the poorer citizens at the expense of the rich, as well as to erect new fortifications and public buildings; and under his strong government Syracuse seems to have been at least quiet and orderly. After his death in 289 comes another period of revolution and despotism; and but for the brief intervention of Pyrrhus in 278 Syracuse, and indeed all Sicily, would have fallen a prey to the Carthaginians.

A better time began under Hieron II., who had fought under Pyrrhus and who rose from the rank of general of the Syracusan army to be tyrant—king, as he came to be soon styled—about 270. During his reign of more than 50 years Syracuse enjoyed tranquillity and seems to have grown greatly in wealth and population. Hieron's rule was kindly and enlightened, combining good order with a fair share of liberty and self-government. His financial legislation was careful and considerate; his laws as to the customs and the corn tithes were accepted and maintained under the Roman government, and one of the many bad acts of Verres was to set them aside. It was a time, too, for great public works—works for defence at the entrance of the Lesser Harbour between the island and Achradina, and temples and gymnasia. Hieron through his long reign was the stanch friend and ally of Rome in her struggles with Carthage.

Capture by the Romans.—Hieronymus, the grandson of Hieron, thought fit to ally himself with Carthage, but he soon fell in a conspiracy. There was a fierce popular outbreak and more bloodshed; the conspirators were put to death and Hieron's family was murdered; whilst the Carthaginian faction, under the pretence of delivering the city from its tyrants, got the upper hand and drew the citizens into open defiance of Rome. M. Claudius Marcellus was then in command of the Roman army in Sicily, and he threatened the Syracusans with attack unless

they would get rid of Epicydes and Hippocrates, the heads of the anti-Roman faction. Marcellus struck his first blow at Leontini, which was quickly stormed; and its sack roused the feeling of the Syracusans against any negotiations with the Roman general, and, putting themselves under Epicydes and Hippocrates, they closed their gates on him. Marcellus, after an unsuccessful attempt to negotiate, began the siege in regular form (214 B.C.) by both land and sea, establishing a camp on Polichne, where stood the old temple of Olympian Zeus; but he made his chief assault on the northern side and on the defences of Tyche. The city was defended by a numerous soldiery and by the ingenious contrivances of Archimedes, whose engines dealt havoc among the Roman ships and frustrated the attack on the fortifications on the northern slopes of Epipolae. Marcellus had recourse to a blockade, and at last, in 212, information was given him that the Syracusans were celebrating a great festival to Artemis. Making use of this opportunity, he forced the *Hexapylon* entrance by night and established himself in Tyche and on the heights of Epipolae. The strong fortress of Euryelus held out for a time, but, being now isolated, it soon had to surrender. The "outer" and the "inner" city of Thucydides still held out, whilst a Carthaginian fleet was moored off Achradina and Carthaginian troops were encamped on the spot. But a pestilence broke out in the autumn of 212, which swept them clean away and thinned the Roman ranks. The ships sailed away to Carthage; on their way back to Syracuse with supplies they could not get beyond Cape Pachynus owing to adverse winds, and they were confronted by a Roman fleet. All hope for the city being now at an end, the Syracusans threw themselves on the mercy of Marcellus; but Achradina and the island still held out for a brief space under the Syracusan mercenaries, till one of their officers, a Spaniard, betrayed the latter position to the enemy, and at the same time Achradina was carried and taken. Marcellus gave the city up to plunder, and the art treasures in which it was so rich—many of the choicest of them, no doubt—were conveyed to Rome. Archimedes perished in the confusion of the sack while he pursued his studies.

Syracuse was now simply one of the provincial cities of Rome's empire. It retained much of its Greek character and many of its finest public buildings. Its importance and historic associations naturally marked it out as the residence of the Roman praetor or governor of Sicily. Cicero often speaks of it as a particularly splendid and beautiful city, as still in his own day the seat of art and culture. Caligula restored its decayed walls and some of its famous temples. It was plundered by Frankish pirates about A.D. 286. In the 4th century it is named by the poet Ausonius, chiefly, perhaps, on the strength of its historic memories; and there was a purple factory here under an imperial procurator. In 665 Heraclius Constans fixed his capital here, but owing to his oppressive government was assassinated in 668. Syracuse has been a place of comparatively little importance since the year 878, when it was destroyed by the Saracens.

Archaeology.—The mediaeval and modern town of Syracuse (with the exception of a new quarter which has sprung up since the construction of the railway between the station and the island) is confined to the island. This contains the remains of two Doric temples. The older, belonging probably to the beginning of the 6th century B.C., appears, from an inscription on the uppermost step, to have been dedicated to Apollo. It was a peripteral hexastyle of 42 columns; the portion excavated shows that its total width is 74½ft., the width of the cella 38½ft., the lower diameter of the columns 6¼ft. The other temple, into which the cathedral was built in A.D. 640, is to be dated 474–460 B.C. It was a peripteral hexastyle of 36 columns, with a total length of 180ft. and a total breadth of 72ft.; the columns have a lower diameter of 5¾ft., and the intercolumniation is 13½ft. It is almost certainly the temple of Athena. The site was previously occupied by buildings of the 7th and 6th centuries B.C., including an archaic temple and a great sacrificial altar, which were destroyed to make room for it. Their terra-cotta decorations were, however, carefully buried under the pavement of the space which surrounded it; and they are of the highest importance in the history of design, showing that even if the method was Corinthian in origin it was in Sicily that it reached its highest development.

Near the west coast of the island is the famous fountain of Arethusa. According to the legend, the nymph Arethusa was changed into the fountain by Artemis to deliver her from the pursuit of the river-god Alpheus (*q.v.*); and the spring, which was fresh until an earthquake broke the barrier and let in the salt water, was supposed to be actually connected with the river. There are interesting remains of mediaeval architecture in the closely built town with its narrow streets; the beautiful 14th-century windows of the Palazzo Montalto may be especially noticed, and also the 13th-century Castello Maniace at the southern extremity of the island. The town also contains the large and well arranged archaeological museum which is the creation of Prof. Orsi, and is of the highest importance for both pre-Hellenic and Hellenic archaeology. The discoveries of recent years in the south-eastern portion of Sicily, including especially the objects found in Sicel and Greek cemeteries, may be studied there. The isthmus connecting the island with the mainland, which was defended by strong fortifications erected by Charles V. and Philip II. (now demolished), does not occupy the site of the mole erected in the 6th or 7th century B.C., running due north from the north point of the island. On the landward side of the new isthmus was the agora, in which remains of a colonnade of the Roman period have been found. To the west are the remains of an extensive building of the Roman period, probably a palaestra with a small Odeum attached. To the west-north-west is an extensive necropolis, mostly of the 7th and 6th centuries B.C. (For the cemeteries see *The Year's Work in Classical Studies*, p. 123 [1924–25].) This necropolis was included within the defensive wall of Dionysius, a portion of which, no less than 18½ft. thick, was found running diagonally across the new cemetery, and later an outwork in front of it was discovered. East of this point it probably followed the edge of the low terrace above the marsh (the ancient Lysimeleia), while in the other direction it ran north-north-west, making straight for the western edge of the gorge known as the Portella del Fusco, which was thus included within the fortifications, as it would otherwise have afforded a means of access to the enemy. Here the wall gained the top of the cliffs which mark the southern edge of the plateau of Epipolae, which from this point onwards it followed as far as Euryelus. The south wall of Epipolae, considerable remains of which exist, shows traces of different periods in its construction, and was probably often restored. It is built of rectangular blocks of limestone generally quarried on the spot. Euryelus, the point where the terrace of Epipolae narrows down to a ridge about 60yds. wide, which is its only link with the hills to the west, had thrice proved during the Athenian siege to be the key to Syracuse. It now bears the ruins of a mighty fortress, finer than that which defends the entrance to the acropolis of Selinus—the most imposing, indeed, that has come down to us from the Greek period—which there is no doubt is the work of Dionysius. The total length of the works is about 440yds. In front of the castle proper are three ditches, the innermost of which can be reached from the interior of the castle by a complicated system of underground passages. The front of the castle is formed by five massive towers; behind it are two walled courtyards, to the north of the easternmost of which is the well-guarded main entrance to the plateau of Epipolae (narrower minor entrances are to be seen on both the north and the south sides) communicating by a long underground passage with the inner ditch in front of the castle proper. On the north side of Epipolae the cliffs are somewhat more abrupt; here the wall, of a similar construction to that on the south, is also traceable, but here it is apparently all of one period. It is, indeed, recorded by Diodorus that Dionysius built the north wall from Euryelus to the *Hexapylon* in 20 days for a length of 2¾m., employing 60,000 peasants and 6,000 yoke of oxen for the transport of the blocks.

The most important buildings of which we have any remains are to be found in the lower part of Achradina and in Neapolis, a quarter of which we hear first in the time of Dionysius, and which at first was confined to the lower ground below Temenites; but in Roman times included it and the theatre also, though it

did not extend beyond the theatre to the uppermost part of the plateau. In lower Achradina remains of Roman private houses have been found, and it is in this district that the early Christians constructed their catacombs. (St. Paul tarried at Syracuse three days on his way to Rome [Acts xxviii. 12].) Those which are entered from near the 12th-century church of S. Giovanni, situated near an ancient temple, are extensive and important, and include the ancient crypt of S. Marcianus, and the type is different from that of the Roman catacombs, the galleries being far larger (partly owing to the hardness of the limestone in which they are excavated), and having circular chambers at the points of junction. In Neapolis, on the other hand, public buildings predominate. The temple of Apollo Temenites has entirely disappeared, but the theatre, entirely hewn in the rock, is still to be seen. It is the largest in Sicily, being 138½yds. in diameter, and having 59 rows of seats; the 11 lower tiers were originally covered with marble. Each of the nine *cunei* or divisions bore a name; the inscriptions of five of them, still preserved on the rock, are in honour of Zeus, Heracles, King Hieron II., his wife Philistis, and his daughter-in-law Nereis. It was restored after 238, after her marriage to Gelon. Of the stage nothing but cuttings in the rock and foundations are visible. (*See* G. E. Rizzo, *Il Teatro Greco di Siracusa* [1923] for a most careful study.) The situation is well chosen, commanding a splendid view over the Great Harbour, and it is often used for classical performances. Not far off to the southeast is the amphitheatre, probably erected by Augustus when he founded a colony at Syracuse; it is partly cut in the rock and partly built. It is inferior in size only to the Colosseum and the amphitheatres of Capua and Verona, measuring about 153 by 130 yd. over all: the arena is 76 by 43 yd. To the west of the amphitheatre is the foundation of the great altar erected by Hieron II., 217 yd. long by 24 wide, and about 6 yd. in height. To the northwest of the theatre a winding road ascends through the rock, with comparatively late tomb chambers on each side of it. In this district are seen hundreds of small niches cut in the rock, as a rule about 2 ft. square and a few inches deep, which served for containing inscriptions or reliefs, sometimes of a sepulchral character, but sometimes relating to the cult of a divinity. Both the districts just described also contain huge quarries, the famous Lautumiae (from Gr. λᾶας, stone, and τεμεῖν, to cut; hence λατομία, quarry) of Syracuse, over 100 ft. deep and of great extent (though through the collapse of the pillars supporting the undermined rock they have become still larger than they were in ancient times).

We have already seen that immediately outside Lower Neapolis on the south the marshes of Lysimeleia begin, which proved fatal to more than one besieging force. They are traversed by the Anapus, with its tributary the Cyane, the latter famous for the papyrus planted by the Arabs, which here alone in Europe grows wild in the stream. To the south of the Anapus is the hill of Polichne, on which stood the Olympieum, attributed on stylistic grounds to 581 B.C. Its monolithic columns, of which two are still standing, are about 21 ft. in height and 6 ft. in lower diameter: its length is estimated at 197 ft., its breadth at 66⅔ ft. This and the temple of Apollo are the earliest known examples of peripteral temples in stone. The hill was frequently occupied in attacks on Syracuse by the besieging force. The hill of Dascon is a trifle to the southeast. From this point southward the shore of the Great Harbour begins to rise, until the rocky promontory of Plemmyrium is reached.

As an important seaport, Syracuse was bombed by the Allies a number of times during World War II. With the rest of Sicily it was occupied by Anglo-American forces in the summer of 1943.

(E. A. F.; T. A.)

SYRACUSE, a city of New York, U.S., and the seat of Onondaga county, is midway between Albany and Buffalo, at the south end of Lake Onondaga (5 mi. long). It is the central city of the Syracuse standard metropolitan statistical area, which encompasses Madison, Onondaga and Oswego counties. Syracuse itself has lost population to the metropolitan area; in 1960 the population of the city was 216,038, as compared with 220,583 in 1950. The metropolitan area by contrast had a population of 563,781 in 1960, a 21.2 increase since 1950. The growth is spreading north to Liverpool, west to Auburn and east to Chittenango, reaching toward Oneida, Rome and Utica to form a single great central New York urbanized region. (For comparative population figures *see* table in NEW YORK: *Population.*)

History.—The site of Syracuse was the home of the Onondagas and the capital of the Iroquois federation called the Five (later Six) Nations, whose founding father was Hiawatha (himself a Mohawk), the legendary chief of the Onondagas. Known also as "The Long House" or "People of Many Fires," they formed a chain of nations, beginning with the Mohawks at the easternmost point and linking the Oneidas, Onondagas, Cayugas and Senecas on the west (*see* also IROQUOIS). The site was visited by the explorers Samuel de Champlain in 1615 and Pierre Esprit, sieur de Radisson, in 1651 (while a captive of the Mohawks) and by Simon Le Moyne, a Jesuit missionary, in 1654. At the site was a spring from which the Indians would not drink because they believed a demon lived in it, giving the water an evil smell; Le Moyne discovered that it was a fountain of salt brine. In 1655 a mission was founded by Fathers Joseph Chaumonot and Claude Dablon, and the next year a military post was founded near the present village of Liverpool (5 mi. N.W. of Syracuse); both were abandoned in 1658 because of the hostility of the Mohawks, but the mission was resumed in 1668 and continued through the century.

The first white settler at Syracuse was Ephraim Webster, who established a trading post there in 1786. In 1788 Asa Danforth, who came to be called "the father of Onondaga county," built a sawmill and a gristmill and organized the militia. In 1788 the state undertook by treaty with the Onondagas to manage the salt springs; in 1795 it acquired title to the springs and 10 sq.mi. of surrounding land in return for $1,000 in cash and promise of an annual rental of $700 and 150 bu. of salt. In 1797 the state began leasing the salt lands on a royalty basis. Three villages soon sprang up around the southern end of the lake: Webster's Landing and Salina in 1797 and Geddes (founded by James Geddes, the first manufacturer of salt on a large scale) in 1803. The landing was known by several names in succession until 1820, when a post office was established and the name of Syracuse was adopted, after the ancient Greek city in Sicily. Syracuse was incorporated as a village in 1825, became the county seat in 1827 and, absorbing Salina, was chartered as a city in 1847. From time to time various annexations of contiguous territory were made, including the village of Geddes in 1886. The Onondaga Indian reservation is located 6 mi. S. of the city.

Government.—Syracuse has a mayor and council form of government. Because of the development of the metropolitan area, especially Onondaga county, local government is tending more toward a county or metropolitan form; for example, by 1950 it was evident that the supply of water then available was insufficient for further industrial development, and in that year the Onondaga County Water authority was created to attack the problem from an area standpoint. The city and county per capita costs of government are average for the cities and counties of upstate New York, as are the property tax rates. The city has a sales tax and is virtually debt free.

Commerce, Industry and Transportation.—The salt industry provided the original economic foundation of the city, as well as the source of its first private fortunes; Syracuse supplied most of the salt for the United States until 1870. Since then, however, the metropolitan area has developed into a manufacturing centre of considerable importance. The principal products are machinery, metal products, food, paper products and chinaware. It is the wholesale trade centre for the central New York region, rivaled only by Buffalo at one side of the state and Albany at the other. Syracuse is situated at the crossroads of central New York and is well served by highways and railroads. Hancock airport is supplemented by numerous other public and private airports. The State Barge canal is within easy reach; four oil pipelines complete the transportation system.

Education and Cultural Activities.—Syracuse is an outstanding educational centre, led by Syracuse university, a private

coeducational institution founded in 1870 by the Methodist Church. Its colleges and schools offer facilities for graduate, professional and adult education; among them are the Maxwell Graduate School of Citizenship and Public Affairs, the college of forestry (a unit of the State University of New York) and a branch college in Utica. Le Moyne, a Roman Catholic coeducational college, was founded in 1946. Nearby are two state university colleges of education, at Cortland and Oswego, and the Auburn Community college, a two-year institute. There are numerous musical and dramatic groups, including summer theatres at nearby Skaneateles and Fayetteville, the Syracuse Museum of Fine Arts, the Lowe Art centre and the Barrows Art gallery (Skaneateles). The Salt museum near Syracuse and Rail City near Oswego feature the history of those industries. The fair grounds, where state fairs have been held since 1890, are at the western edge of the city.

Recreation.—The recreation opportunities of the city and area include many fine places for hunting, camping, boating, swimming and fishing; eight state parks in the Finger lakes region; Onondaga lake; Lake Ontario and Oneida lake; and the famous Adirondack park. (V. C. C.)

SYR-DARYA (Gr. and Lat. *Jaxartes;* Arab. *Shash* or *Sihun*), (1) a river of Asiatic Russia, flowing into the Sea of Aral, and having a length of 1,370 mi. and a drainage area of about 178,378 sq.miles. Its headstream is the Naryn, rising in the Tianshan south of Lake Issyk-kul, on the south slope (12,000 ft.) of the Terskei Ala-tau. After union with the Barskaun, it flows W.S.W. at 11,000 to 10,000 ft. above the sea, in a barren longitudinal valley between the Terskei Ala-tau and the foothills of the Kokshal-tau. As the Naryn it flows through a wild gorge in the south-west continuation of the Terskei Ala-tau, falling 4,000 feet. Fort Narynsk, 20 m. below the confluence of the Great and the Little Naryn, is only 6,800 ft. above the sea. Here the river enters a broad valley—formerly the bottom of an alpine lake—and flows past the ruins of Fort Kurtka, for 90 m. westward, as a stream some 50 yd. wide and from 3 to 11 ft. deep, used by the Kirghiz for irrigating their cornfields. The At-bash, a large mountain stream, joins the Naryn at the head of this valley and the Alabuga or Arpa at its lower end, both from the left. Before reaching the lowlands the Naryn cuts its way through three ridges which separate the valley of Kurtka from that of Ferghana, and does so by a series of wild gorges and open valleys (170 m.), representing the bottoms of old lakes; the valleys of the Toguztorau, 2,000 ft. lower than Kurtka, and the Ketmen-tube are both cultivated by the Kirghiz. Sweeping north, the river enters Ferghana—also the bottom of an immense lake—where, after receiving the Kara-darya (Black River) near Namangan, it assumes the name of Syr-darya. The Kara-darya is a large stream rising on the northern spurs of the Alai mountains. As it deflects the Naryn towards the west, the natives look upon it as the chief branch of the Syr-darya, but its volume is less. At the confluence the Syr is 1,440 ft. above sea-level.

On issuing from this gorge the Syr enters the Aral depression, and flows for 850 m. in a north-westerly and northerly direction before reaching the Sea of Aral. On this section it is navigated by steamers. Between the Irjar rapids and Baildyr-turgai (where it bends north) the river flows along the base of the subsidiary ranges which flank the Chotkal mountains on the north-west, and receives from the longitudinal valleys of these alpine tracts a series of tributaries (the Angren, the Chirchik, the Keles).

Some 50 m. below Chinaz (770 ft. above sea-level) the Syr bends northwards, but resumes its north-westerly course 150 m. farther down, following with remarkable persistency the edge of the loess. Its low banks, overgrown with reeds and rendered uninhabitable in summer by clouds of mosquitoes, are inundated for 20 m. on both sides when the snows begin to melt. These inundations prevent the moving sands of the Kyzyl-kum desert from approaching the Syr; below Perovsk (Kzyl-Orda, or Ak Mechet) the steppe conquers. Down to Perovsk the river rolls its muddy yellow waters, at the rate of 3 to 5 m. an hour, in a channel 300 to 600 yd. wide and 3 to 5 fathoms deep; at Perovsk its vertical section is 8,220 sq.ft., and 312,500 cu.ft. of water are discharged per second. The Arys and the Bugun are the only tributaries worthy of notice along this part of its course; the other streams which descend from the Kara-tau fail to reach the river. The Kirghiz rear numerous herds of cattle and sheep in the valley of the Arys, while lower down, as far as Julek, the Iginchis carry on agriculture. All this applies of course only to the right bank; on the left the moisture is absorbed by the hot winds which cross the Kyzyl-kum sands towards the river. The dryness of the atmosphere has a marked effect upon the Syr when it gets below Julek, the Kara-kum sands being then on its right. Ten miles below Perovsk the river traverses a marshy depression (the bottom of a lake not yet fully dried up), where it divides into two branches—the Jaman-darya and the Kara-uzyak. The latter spreads out into marshes and ponds, from which it again issues to join the former at Karamakchi, after a course of 80 miles. The main arm, owing to its shallowness and sinuosity, is very difficult to navigate, and the difficulty is increased by the rapidity of the current and the want of fuel. Between Kazalinsk and the Sea of Aral (158 ft.) navigation becomes somewhat easier, except for the last 10 m., where the river divides into three shallow branches before entering the "Blue sea." All three have at their mouths sandy bars with only 3 ft. of water.

Two former right-hand tributaries of the Syr—the Chu and the Sary-su—now disappear in the sands some 60 m. before reaching it. The Chu, which is 600 m. in length, rises in the Tian-shan south-west of Lake Issyk-kul, and as the Kashkar flows towards Lake Issyk-kul, but a few miles before reaching that lake turns suddenly to the north-west, enters under the name of Chu the narrow gorge of Buam, and, piercing the snow-clad Kunghei Ala-tau, emerges on its northern slope, having descended from 5,500 ft. to less than 2,000 in a distance of not more than 50 miles. In this part of its course it receives from the right the Kebin, whose high valley equals in size that of the upper Rhone. It then flows north-westwards through the valley of Pishpek, and, avoiding the Muyun-kum sands, describes a wide curve to the north before finally taking a western direction. Numberless streams flow towards it from the snow-clad Alexander mountains, but they are for the most part lost in the sands before reaching it. The Talas, 170 m. long, formerly an affluent of the Chu, which rises in the highest parts of that range, pierces the Cha-archa mountains, and, flowing past Aulie-ata on the south border of the Muyun-kum, enters the salt lake of Kara-kul 60 m. from the Chu. The Chu terminates in the Saumal-kul group of lakes, 60 m. from the Syr. Another elongated group of lakes—the Uzun-kul—near the above, receives the Sary-su, which has a length of nearly 570 m. and flows rapidly in a narrow channel along the western edge of the northern Famine Steppe (Bekpak-dala).

The delta of the Syr begins at Perovsk, whence it sends a branch to the south-west, the Jany-darya (New River), which formerly reached the south-eastern corner of the Sea of Aral, very near to the mouth of the Amu-darya. The Kirghiz affirm that a canal dug for irrigation by the Kara-kalpaks gave origin to this river. It had, however, but a temporary existence. A dam erected by the people of Khokand at Ak-mechet (Perovsk) caused its disappearance, and the Russians found nothing but a dry bed in 1820. When the dam was removed the Jany-darya again reappeared, but it failed to reach the Sea of Aral; in 1853 it terminated in Lake Kuchka-denghiz, after a course of 250 m.; all traces of its bed were then lost in the sand. Five centuries ago, in the time of Timur, the Mongol prince of Samarkand, the Jany-darya brought the waters of the Syr to the Daukara lakes, close by the present mouth of the Amu. The series of old river-beds in the Kyzyl-kum, which are still seen above Perovsk, indicate that the Syr had a constant tendency to seek a channel to the south-west, and that its present delta is but a vestige of what it was once. At a still more remote period this delta probably comprised all the space between the Kara-tau and the Nura-tau in Samarkand; and the series of elongated lakes at the base of the Nura-tau—the Tuz-kaneh and Bogdan-ata lakes—represent an old branch of the delta of the Syr which probably joined the Zarafshan before reaching the Amu. The cause of this immense change is simply the rapid desiccation of all northern and central Asia. The extension of the Caspian sea as far as the Sary-kamysh lakes

during the post-Pliocene period and the extension of the Sea of Aral at least 100 mi. to the east of its present position are both proved by the existence of post-Pliocene marine deposits.

(2) A former province of Asiatic Russia, now included in the Kazakstan A.S.S.R. and Uzbek A.S.S.R. (*qq.v.*).

SYRIA, a geographical name applied at different epochs to different areas. In ancient times Syria was the fertile strip between the eastern coast of the Mediterranean and the Arabian desert, from the Gulf of Alexandretta to Sinai. It included therefore the territories of the modern states of Lebanon, Israel and Jordan. The name Greater Syria, used in the 20th century by Arab nationalists, vaguely corresponds to this definition.

Lying as it does where three continents converge, Syria was usually part of larger empires; Hittites, Egyptians, Babylonians and Persians successively dominated the country. Alexander of Macedon conquered it. In the 1st century B.C. it became a Roman province. As part of the Eastern Roman empire it was again invaded by the Persians and later by the Arabs, becoming in the 7th century part of the caliphate. Turkish, Mongol and Mameluke invasions, as well as crusades fill the period from 11th to the 16th century when Syria was incorporated in the Ottoman empire.

After World War I it came under the French mandate, but without Palestine and Transjordan.

After World War II the independent states of Syria and Lebanon (*q.v.*) were created from the French mandated territory. This independent Syria is bordered on the northwest and on the north by Turkey, on the east and on the southeast by Iraq, on the south by Jordan and Israel and on the west by Lebanon and the Mediterranean.

Physiography.—The whole area of the states of Syria and Lebanon (*q.v.*) may be regarded as a single geographical unit extending from the eastern shore of the Mediterranean to the Syrian desert (which is crossed diagonally from northwest to southeast by the Euphrates) and the Jazirah east of that river. It is bounded on the north by the foothills of the Taurus ranges and terminates south of the Anti-Lebanon and Mount Hermon with the volcanic region of the Hauran and the Jabal Druse. The coastal strip is a narrow, discontinuous plain measuring about 200 mi. in a direct line from Kara Duran on the northern frontier to Ras an-Nakurah (Ras en Naqura) in the south. There are many varieties of shore line, from the cliffs and headlands north of Latakia and the rugged coast between Tripoli and Beirut, to the sandy shore near Tyre. Behind, from north to south, lie the Ansariyah and Lebanon ranges divided by the valley of the southern Nahr al-Kabir (the ancient Eleutherus). The Ansariyah averages 18 to 20 mi. in width and is of fairly uniform, rounded outline intersected by deep valleys. The highest peak, Nebi Yunis (5,194 ft.), is toward the northern end of the range. The Lebanon rises steeply from the Bika (Bekaa) plain to a tableland more than 8,000 ft. high from which rise several peaks, the highest being Kurnat as-Sauda (Qurnet es Sauda) (10,131 ft.). The main pass, which carries the Beirut-Damascus road, is the Dahr al-Baidar (5,057 ft.). South of this pass the main ridge is narrower and falls away southeast to the plain of Merj Ayun, south to the Litani gorge and southwest to the coast near Sidon. The upper slopes of the Lebanon are bleak, stony and desolate; the middle slopes, below 5,500 ft., are the most densely populated region and cultivation extends up to 5,200 ft. East of the coast ranges is a long depression. At the northern end are the Orontes valley and the Ghab marshes which extend for 38 mi. from north to south with a maximum width of about 9 mi. South of the Ghab the Orontes follows a tortuous course to Lake Homs, south of which is the Bika valley. The northern end of this valley, through which the Orontes flows is, for the most part, poor soil strewn with basalt boulders mixed with limestone and flint. South of the Baalbek ridge, the watershed between the Orontes and the Litani, the soil is rich and well-cultivated. The Litani river falls very gradually through it from northeast to southwest until it reaches the barrier of Jabal Gharbi, a low ridge between the Lebanon and Mount Hermon. The Bika valley is dominated on the east by the Anti-Lebanon range which runs from northeast to southwest nearly parallel with the Lebanon. The main ridge (8,300 ft.) rises steeply about 17 mi. south of Homs and extends for 65 mi. to the Zebdani depression through which pass the railway and road between Beirut and Damascus. Mount Hermon (9,232 ft.) rises south of this gap. Northeast of Damascus are the three Kalamun ridges, the easternmost of which stretches for more than 130 mi. to Palmyra. Northwest of Palmyra lies a semiarid steppe sloping eastward to the Euphrates. The Syrian desert, the Hamad, to the east of the Anti-Lebanon, comes up in places almost to the foot of the range. Where water is available (as in the Ghuta around Damascus which owes its fertility to the Barada [the Abana of the Old Testament]), or rainfall is abundant (as in the Hauran farther south), cultivation pushes out toward the desert. East of the Hauran lies the Jabal Druse (5,900 ft.), much of which is fertile though large areas of the district are lava-covered. To the northeast of the Euphrates is the Jazirah, roughly triangular in its Syrian portion, with a projection in the northeast (the "Duck's Bill") to the Tigris between Jazirat-ibn-Omar (in Turkish Cizre) and Faish Khabur. Except in the neighbourhood of the Euphrates and its tributaries, the Balikh and the Khabur, which cross the Jazirah from north to south, it is a district of stony hills and low ridges.

Climate.—Syria has a climate varying from the Mediterranean type in the west through the steppe type to the continental or extreme type, with a wide range of temperature and absolute aridity for six months, in the inland region, which is open to the Arabian desert on the south. The two gaps in the mountain ranges screening the interior from the sea cause an extension of the maritime influence inland to the region south of Homs and to the Hauran and Jabal Druse south of Damascus. The rainy season is from November to March, though abundant rainfall may occur in April or May. The average of rainfall varies from 20–40 in. in the coastal belt (rising to 50 in. or more in the mountains), through 10–20 in. between Aleppo and Damascus, to 5–10 in. in the crescent from Damascus to the northern frontier and to Dair az-Zor (Deir) and to as little as 0.5 in. in the desert from Palmyra to the southeast. Snow falls on the mountains and may lie even on Mount Hermon until late in the summer. Normally Syria has a hot summer and a mild winter. Temperatures increase from west to east and also, though to a lesser extent, from north to south. Summer temperatures, taking an average over a number of years, vary from mean monthly maxima and minima (August) of 106° F. and 68° F. at Aleppo to 110° and 65° at Palmyra, with absolute maxima at Aleppo (115° F.), Damascus (113°), Palmyra (120°) and Dair az-Zor (115°). Mean monthly maxima and minima for January, which is usually the coldest month, are: Aleppo 58° F. and 22° F., Damascus 62° F. and 28° F., Palmyra 62° F. and 25° F.

(K. C. B.)

Vegetation.—The coastal strip of Syria is intensely cultivated and planted with groves of mulberries, olives, etc., and there is little space for natural flora. Rocky patches bear brushwood with *Calycotome villosa*, buckthorn, tamarisk, etc.; in swampy places reed-grasses grow; and among the crops brilliant flowers of the Mediterranean element such as *Anemone coronaria*, *Ranunculus asiaticus*, *Papaver syriacum*, etc., spring up wherever possible. There is high forest of Aleppo pine in the north of the Ansariyah range with sessile and Syrian oaks (*Quercus syriaca*); in the centre are stunted oak woods; in the south mulberry, valonia oak (*Q. aegilops*), etc. The shrub constituent includes rock roses, tamarisk, terebinth, oleander, etc. On the Lebanon mountains there are forests of oaks, Aleppo pine, cypress, juniper, cedar and fir. Near Beirut there has been considerable re-afforestation with stone pine, and large areas of the lower slopes, up to 5,000 ft., are planted with olive, fig and mulberry (for silkworms). Wild plants in this zone include valerian and danewort, and above, where wheat and barley are cultivated (up to 6,000 ft.) is the montane region of sea holly and rhododendrons. The alpine zone supports peculiar plants such as *Acantholimon libanoticum*, a spiny milk vetch which grows in clumps, and sainfoin. The Bika plain is almost treeless while composites, labiates and milk vetches are characteristic. On the foothills of the steppes terebinth predominates; on the plains

wormwood; and in the Jabal Druse maquis with forests of kermes oak. The Hamad supports only halophytes and xerophytes except along the Euphrates and other water courses where poplars, tamarisk and a few others flourish.

Fauna.—In the upper regions of the Lebanon bear is still occasionally found—the largest remaining wild animal in Syria. Antelope and gazelle are common in the Hamad. Other mammals include deer, polecat, wild cat, ichneumon, porcupine, hedgehog, squirrel, marten, ermine, otter, dormouse, rats, hares and the hyrax. Many migrating birds call at Syria on their way north and south. Flamingoes, pelicans, cormorants, ducks, herons, snipe, etc., frequent the fresh waters and marshes; bustards and ostriches the desert; kingfishers, cuckoos, woodpeckers, etc., the valley; eagles, buzzards, kites and falcons the mountains. Horned and other vipers occur in the desert, and lizards and chameleons are common. Of innumerable insects, the mosquito is the most harmful but locusts and grasshoppers also do damage. In the lakes and rivers mullet, eels and bass are among the fish. (X.)

HISTORY

Flint implements of palaeolithic types have been found in caves in Syria and in Palestine, associated with bones of the rhinoceros and of the hippopotamus and, in the district of Mount Carmel, with skeletal remains of a manlike creature (these dating to the Mousterian period). The remains and industries of man, who already made use of fire, continue through the late Palaeolithic into the Mesolithic age, which is well represented in the so-called Natufian culture found chiefly near Jerusalem. This was the work of men who appear to have been smaller than their predecessors and might be racially similar to the Hamites and Semites. At first purely hunters, they began, before the end of the Mesolithic period, to cultivate the wheat and barley which, in their wild state, were indigenous to the country; and thus they made the decisive step from a nomadic to a sedentary life in which the arts of civilization could be born. Rough pottery is found in a very early age (perhaps *c.* 4000 B.C.) at Jericho, and not long afterward there was centred in northern Syria and in northern Mesopotamia a prehistoric manufacture of the finely made and beautifully painted ware named after Tell Halaf, the place of its first discovery. At about the same time began the use of copper for tools and ornaments. Oxen, sheep, goats and pigs were domesticated, and even irrigation was practised. Population was mixed, the heavier Armenoids being mingled with a slighter race, which may already have spoken a Semitic language.

EARLY HISTORY

History begins with the invention of writing, which took place in southern Babylonia perhaps *c.* 3500 B.C., the script being an original picture-character which developed later into cuneiform. An early Sumerian ruler of the city of Erech, named Lugal-zaggisi, recorded his triumphal progress from the lower sea to the upper (*sc.* the Mediterranean), and this may be taken as the first mention of the land of Syria, though not of the name, in history. Immediately after this mention, Syria appeared as the provenance of a great migration of Semitic invaders into Babylonia by way of the Euphrates, the first of several such movements which may all have begun from northern Arabia, but are never traceable farther back than Syria. These first intruders have been given the name of Accadians, from their leader, Sargon of Agade or Akkad, with whom is connected a legend that he was born obscurely on the upper Euphrates, launched on the river in a reed basket and adopted in Babylonia, where he found favour with a king, supplanted him and became the greatest conqueror and the most famous name in Babylonian history. From his new city of Agade he marched back up the Euphrates to the "cedar mountain" (the Amanus) and far beyond, if the various sources may be trusted. It is probable that he and his equally famous grandson Naram-Sin (*c.* 2300 B.C.) ruled effectively over the whole of Syria, to which they doubtless introduced the Sumerian writing that they had learned and adapted to their Semitic language in Babylonia. But their successors were feebler men, and the dynasty of Agade was soon overthrown at its centre and superseded by the dynasty of Ur. Nothing certain is known about the authority (if any) that the kings of Ur exercised in Syria, so far away from their capital. The end of their dynasty, however, was brought about chiefly by the pressure of a new Semitic migration from Syria, this time of the Amorites (*i.e.*, the westerners), as they were called in Babylonia. Their invasion began before 2000 B.C. and by the 18th century B.C. they had covered both Syria and Mesopotamia with a multitude of small principalities and cities, mostly governed by rulers bearing some name characteristic of the Semitic dialect that the Amorites spoke. The period of Amorite ascendancy is vividly mirrored in the Mari letters, a great archive of royal correspondence found at the site of Mari, near the modern frontier with Iraq. They treat of the wars and general affairs of a multitude of states extending from northern Palestine to the upper Tigris. Among the principal figures in them are the celebrated lawgiver Hammurabi of Babylon (himself an Amorite) and a king of Aleppo, reckoned the most powerful of all, but of whom little is yet known. Part of his kingdom was the city of Alalakh, on the Orontes near what was later Antioch. This has yielded to excavation records both of the Amorite period and of a later age.

At about the same time (later in the 18th century B.C.) there began from Syria a movement of people in the opposite direction. This resulted in the Hyksos invasion of Egypt, which was subject to this foreign domination for about 150 years. The mixed multitude of the Hyksos certainly included Khurrians (Hurrians, Horites), who, not being Aryans themselves, were under the rule and influence of Aryans and learned from them the use of light chariots and horses in warfare, which they introduced both into Egypt and into Syria and Mesopotamia. These Khurrians established the kingdom of Mitanni, with its centre east of the Euphrates, and this was for long the dominant power in Syria, reaching its height in the 15th century B.C. But other nations were growing at the same time, and in the 14th century Syria was the arena in which at least four great competitors contended. The Khurrians were first in possession, and these maintained friendly relations with Egypt, which, after expelling the Hyksos, had established a vast sphere of influence (it was scarcely an "empire") in Palestine and Syria, under the kings of the 18th Dynasty. Third of the powers disputing Syria in the 14th century were the Hittites, who finally, under their greatest warrior Shuppiluliumash (*c.* 1350 B.C.) not only defeated the kingdom of Mitanni but established a firm dominion of their own in northern Syria with its principal centres at Aleppo and Carchemish. Fourth was the rising kingdom of Assyria which became a serious contender in the reign of Ashuruballit I. Indeed a fifth actor also appeared on the scene, the king of Babylon, but he was too distant and impotent to affect the issue. This was the period of the Amarna letters which vividly illustrate the decline of Egyptian influence in Syria, especially under Amenhotep IV (Ikhnaton), the distress or duplicity of local governors and the rivalry of the aforesaid powers, contending with Egypt and with one another in a strife that was not to leave any of them with a final victory. Egyptians and Hittites continued their struggle into the 13th century, but even the famous battle of Kadesh, which Rameses II so boastfully claimed to have won (*c.* 1285 B.C.) led to no more than a treaty maintaining the equal balance. Assyria had already swept away the remains of Mitanni but soon fell into decline, and the Hittites were not long afterward driven from their centre in Asia Minor into a chain of minor states on the northwestern fringes of Syria by the migration of "peoples of the sea," western invaders from the isles of the Aegean and from Europe. These immigrants then marched down the coast of the Levant and threatened Egypt, but were repulsed by Rameses III *c.* 1190 B.C.

While all the neighbouring states had failed to establish a lasting ascendancy in Syria, the actual possession was assumed gradually by a people without sufficient cohesion to appear as a power at all. Various documents of the 14th century mention the Akhlamu, who were forerunners of another vast movement of Semitic tribes called generically Aramaeans. By the end of the 13th century these had covered with their small and loose principalities the whole of central and northern Syria and a great part of Mesopotamia. The Assyrians, however, were able to guard their homeland from this penetration: henceforth much of the warfare of Assyrian kings

was to be a mixture of aggression and defense aimed at the Aramaean states of Syria and at the borderland "Hittite" principalities. At about the same time as the Aramaean invasion there was proceeding the exodus of Israelite tribes from Egypt; and as these, toward the end of the 11th century established a kingdom centred upon Jerusalem, so did the Aramaeans set up their principal kingdom at Damascus, and the wars between kings of Judah or of Israel and kings of Aram make up much of Old-Testament history. But the most formidable enemies of the Aramaeans and often of the Hebrews as their allies, were the great military kings of the Assyrians. After a premature Assyrian incursion under Tiglath-pileser I early in the 11th century B.C., the real contest was reserved for the 9th and the 8th, during which the Assyrian empire was established over the west, though destined to be short-lived. At the battle of Karkar in 853 B.C. Shalmaneser III of Assyria was opposed by Ben-Hadad of Damascus, Ahab of Israel and by 12 vassal monarchs. In 732 Damascus, the Syrian capital, was at length captured by Tiglath-pileser III. But campaigns against the Aramaeans and Anatolians of northern Syria (called "Hatti-land") had to be undertaken by the Assyrians until almost the end of the Assyrian empire. Culturally, the most important achievement of the Aramaeans was the bringing of the alphabet into general use for public and private business. It had been invented along the Syrian coast before the middle of the 2nd millennium B.C. This was perhaps the greatest single contribution ever made to human civilization.

Before the close of the 8th century B.C. began a massive southward movement of people, partly of Aryan stock, from the north and west. Pressure of these upon the Assyrian dominions and homeland became ever more severe, and they deeply affected Syria also; and in the 7th century came the invasion of the Cimmerians, followed by the Scythians. To these and to the Medes, another Aryan people, Assyria finally succumbed with the fall of Nineveh in 612 B.C. A remnant supported itself in Harran for a year, but that city was evacuated before the advance of the Medes, now reinforced by Nebuchadrezzar, king of Babylon. Nebuchadrezzar finally defeated the attempted rescue of Assyria by Necho, king of Egypt, and annihilated his army at Carchemish in 605 B.C. In 586 B.C. he captured Jerusalem and carried its people into exile. Thereafter Syria was, for half a century, under the rule of Nebuchadrezzar's successors on the throne of Babylon. But another and greater Aryan power, the Persians, then came to the fore. Under the leadership of Cyrus they subverted the rule of the Medes and assumed their empire, extending their conquests into Asia Minor, where Cyrus defeated and captured Croesus of Lydia. No longer able to brook a rival, he thus came to a final collision with Babylon, which he occupied in 539 B.C. He returned all the gods of Babylonia to their own places, and among the measures of restoration commanded by him and continued by his successors was a project of sending back the exiled Jewish community to Jerusalem and encouraging them to rebuild the temple. In Darius I's great organization of the Persian dominions more than 20 satrapies were constituted; Syria, with Palestine and Cyprus, was the fifth, bearing the name of "Across the River" (*i.e.*, the Euphrates), and its tribute was fixed at 350 talents of silver. Damascus and the Phoenician cities were still the chief centres of Syria under the Persians, and in Sidon was the core of the Phoenician revolt against Artaxerxes III, which ended with the destruction of that city in 351 B.C. But by this time the end of the Persian domination was at hand, and the Macedonians under Alexander the Great were about to bring the whole near east under Greek rule and influence.

Alexander invaded Asia Minor in 334 B.C., and his first decisive victory over the Persians was won on the fringe of Syria at Issus in 333; it was followed by the capture and enslavement of Tyre and Gaza. With the battle of Gaugamela and the destruction of Persepolis the downfall of Persia was completed.

HELLENISTIC AND ROMAN SYRIA

After Alexander's death in 323 B.C. his marshals contended for control of the country, until after Ipsus (301) Seleucus I Nicator gained the northern part and Ptolemy I Lagus gained the southern (Coele Syria). This partition between the Seleucids and Ptolemies was maintained for 100 yr. despite intermittent Syrian wars during the 3rd century (*see* SELEUCID DYNASTY). Their administrative methods varied. In the south the Ptolemies respected the existing autonomous cities, imposed a bureaucratic system on the rest of the country and established no colonies, while the Seleucids divided their part into four satrapies which embraced the cities, and founded many cities and military colonies (including Antioch, Seleucia Pieria, Apamea and Laodicea [*qq.v.*]), drawing on settlers of European blood. Republics replaced kings in the Phoenician coastal cities of Tyre (274 B.C.), Sidon, Byblus and Aradus. Further political and cultural changes followed. Antiochus III the Great defeated Ptolemy at Panium (200 B.C. or perhaps as late as 198) and thus secured control of southern Syria, where he introduced the satrapal system. His subsequent defeat by the Romans at Magnesia (Dec. or Jan., 190–189), however, diminished both his territory in Asia Minor and his prestige, thereby fundamentally weakening the Seleucid empire, which ceased to be a Mediterranean power. Antiochus Epiphanes (175–163) stimulated the spread of Greek culture in Syria, with which went Greek political ideas, by a policy of urbanization: increased city organization and municipal autonomy involved greater decentralization of his kingdom; his attempted hellenization of the Jews is well-known. Under the later Seleucid kings, with rival claimants to the throne and constant civil war, Syria disintegrated. In the north the Seleucids controlled little more than the areas of Antioch and Damascus (Coele Syria): Commagene asserted its freedom, many of the cities claimed independence and numerous petty chiefs established little principalities. Southern Syria was partitioned by three tribal dynasties, the Ituraeans, the Jews and the Nabataeans. The country was seized later by Tigranes of Armenia (83) until his defeat by Pompey who ended years of anarchy by making Syria a Roman province (64–63).

Pompey in the main accepted the status quo, but he re-established a number of cities and reduced the kingdom of Judaea; 10 cities of the interior formed a league, the Decapolis. The Roman province of Syria therefore included the native kingdoms of Commagene, Ituraea, Judaea and Nabataea. A Parthian invasion was thrown back in 39 B.C., while Antony's extensive territorial gifts to Cleopatra (Ituraea, Damascus, Coele Syria, etc.) involved only temporary adjustments. Under the principate Syria, which stretched northeast to the upper Euphrates and, until A.D. 73, included eastern Cilicia, became one of the most important provinces. Its governor, a consular legate, generally commanded four legions until A.D. 70. Administrative changes followed; Rome gradually annexed the client kingdoms. Ituraea was incorporated (*i.e.*, its territories were assigned to neighbouring cities) partly in 34 B.C., partly *c.* A.D. 93. Judaea became a separate province in A.D. 6, governed by procurators (apart from Herod I Agrippa's shortlived control, A.D. 37–44), until the destruction of Jerusalem in 70. Then the governor was a praetorian legate in command of a legion; next, under Hadrian he was a consular with two legions, and the province was named Syria Palaestina. Commagene was annexed temporarily from A.D. 17 to 38 and permanently by Vespasian in 72. The caravan city of Palmyra came under Roman control, possibly during Tiberius' reign. Finally, Nabataea was made the province of Arabia in 105, governed by a praetorian legate with one legion. Syria itself was later divided by Septimius Severus into two provinces—Syria Coele in the north with two legions, and Syria Phoenice with one. By the beginning of the 5th century it was subdivided into at least five provinces. The frontiers of Syria were guarded by a fortified *limes* system, which was thoroughly reorganized by Diocletian and his successors (particularly against cavalry attacks) and endured until the Arab conquest; much knowledge of this system of "defense in depth" has been obtained with the aid of air-photography.

Syria's economic prosperity depended on its natural products (*e.g.*, wine, olives, vegetables, fruits and nuts), on its industries (*e.g.*, purple-dyeing, glassmaking at Sidon, linen and wool weaving and metalwork) and on its control and organization of trade passing by caravan from the east to the Mediterranean through such

centres as Palmyra, Damascus, Bostra and Petra. Further, Syrian merchants spread westward throughout the Latin provinces of the Roman empire. The population of the country must have been larger than that of today. Some cities were founded under the empire, but these were not numerous and Syria remained essentially rural. The urban upper and middle classes might be hellenized, but the lower classes still spoke Aramaic and other Semitic dialects in town as well as country. Roman influences were naturally weaker than Greek, though the army at first helped the spread of romanization, while Latin, not Greek, was the language of instruction in the famous law school at Berytus until *c.* A.D. 400. The splendour of Syrian culture is seen in the magnificence of the cities (Antioch, ranking among the greatest cities of the empire, was the residence of the governor and later of the *comes Orientis*), and in the luxury, gaiety and versatility of the Syrians. This splendour is also evident in their schools of rhetoric, law and medicine, in their art (the pre-eminence of Italian or Syrian elements in Syrian art is debated), in their literature and philosophy and in the variety of their religions, both pagan and Christian.

During the three centuries Syria was administered from Constantinople, its cultural and economic life remained active, as names like Libanius, Ammianus Marcellinus, Procopius and John Malalas bear witness. Government became more bureaucratic but it was efficient. From the middle of the 5th century, by which time paganism had died out and monasticism was spreading, religious controversy took a political turn with the growth of the Monophysites, in whom anti-imperial, nationalist and secessionist sentiment found a rallying point. The repercussions of this heresy seriously weakened Syria and the Eastern Roman empire. Nor were external dangers lacking. In the 4th century, during the campaigns of Constantius and Julian against Persia, Syria had again become a base of operations and at times endured Persian invasion; and the Huns had appeared before the end of that century. The Persian menace died down during the 5th century, but it blazed up again in the 6th, when Arabs also added to the danger. The Persian Chosroes I captured Antioch itself (540); and though he was outwitted by Belisarius and though Justinian's Persian wars ended in a "50 years' peace" (562), yet ten years later the Persians were back again. The invasion of Chosroes II, which began in 606, was later rolled back by the victories of Heraclius, but the peace of 628 brought no tranquillity to Syria. The Arabs advanced, Damascus and Antioch fell, and Heraclius was forced to evacuate Syria: Islam was master of the land which seven centuries earlier Pompey had formally added to the Roman empire.

MEDIAEVAL SYRIA

In 633 the Mohammedan Arabs invaded Syria from the south. After their decisive victory on the Yarmuk river in 636 they occupied the whole country piecemeal and made it a base for further conquests north and west. When civil war broke out in 656, the Arabs of Syria stood firm behind their governor, Mu'awiya, of the Meccan house of the Omayyads, who, after warding off at Siffin an attack by the Iraqi Arabs, extended his authority over the neighbouring provinces and was recognized as caliph in 661 (*see* CALIPHATE).

During the Omayyad caliphate (661–750) Damascus was the capital of an Arab empire which, despite internal outbreaks, extended by 715 from Spain and Morocco to Turkistan and Sind and held the mastery of the Mediterranean. With the wealth drawn from the dependent provinces the caliphs 'Abd ul-Malik and Walid I endowed Jerusalem and Damascus with magnificent religious monuments, the Dome of the Rock and the Omayyad mosque. The first serious setback was the failure of the third and final Arab assault on Constantinople in 719. During the following decades unrest and weakness in the outer provinces involved the wide dispersion of Syrian troops on expeditions and garrison duty; this, combined with factional feuds among the Arabs, undermined the military power of the Omayyads, who were finally overthrown by the Khurasanian army of the new Abbasid caliphate in Iraq in 750.

Under the Abbasids Syria reverted to the status of a dependent province. It had little share in the economic and cultural development of the Abbasid empire and was increasingly abandoned to its sedentary Arab population and to the nomads on the desert frontiers. As the empire disintegrated, Syria was annexed, in whole or in part, by the Egyptian dynasties (Tulunids, Ikhshidis, Fatimites), except for the brief principality of the Arab Hamdanids of Aleppo founded by Saif ud-Daula (944–967), whose early successes against the Byzantine empire were followed by the Greek recovery of Antioch (969).

During the 11th century the fragmentation of Syria was momentarily arrested by its unification under the Seljuk Tutush (1078–95) and attachment to the empire of his brother, the sultan Malikshah (*see* SELJUKS). On his death the Seljuk kingdom fell to pieces, and Antioch, Jerusalem, the coastal regions and Kerak (Trans-Jordan) were occupied by the crusaders against feeble local opposition between 1098 and 1124 (*see* CRUSADES). The Mohammedan counterattack began with the annexation of Aleppo by the Turkish atabegs of Mosul (1125), with the recovery of Edessa (1144), and with the union of inner Syria under Nureddin (1146–74), who also annexed Egypt in 1169. After Nureddin's death his principality was rebuilt and enlarged by his Kurdish viceroy in Egypt, Saladin (*q.v.*) (1174–93), who recovered all of Palestine and most of the inland crusader strongholds after his victory at Hattin (1187) but lost the Palestinian coast again as a result of the third crusade. Concurrent developments of the 12th century were the rise to power of the sect of the Assassins (*q.v.*) and the rapid proselytism conducted by the Druzes (*q.v.*).

The crusades, paradoxically, did much to rehabilitate inner Syria, both by the economic development resulting from the establishment of Italian trading centres on the coast and by the impetus given to its cultural life by Nureddin and Saladin. Although it was again split up after Saladin's death between the members of his family, the Ayyubites, who established separate principalities in Aleppo, Hama, Homs, Damascus, Baalbek and Trans-Jordan and disturbed by intermittent hostilities between their princes or against the crusaders, Syria as a whole regained during the Ayyubite period (1193–1260) a level of prosperity such as it had not enjoyed since the 3rd and 4th centuries. A severe blow was dealt by the first Mongol invasion and sack of Aleppo in 1260, but the Mongols were thrown back by the Mameluke sultans of Egypt, who re-organized the Ayyubite principalities as Mameluke governorships and completed the expulsion of the crusaders by 1291. After the defeat of a fourth Mongol invasion in 1304 Syria remained relatively peaceful and prosperous as a centre of culture, learning and industry under Mameluke rule until the invasion of Timur (*q.v.*) in 1400. From this fresh blow its economy never really recovered, and it continued to decay slowly under the later Mamelukes until its annexation in 1516 by the Ottoman sultan Selim I, who divided it into three Turkish pashaliks. Its incorporation in the Ottoman empire brought some revival of economic prosperity to Aleppo and Damascus through trade and the pilgrimage to Mecca but did not arrest the decline of agriculture and general security under the pressure of nomad tribesmen. (H. A. R. G.)

THE 19TH AND 20TH CENTURIES

For nearly three hundred years, then, the history of Syria was that of a province of the Ottoman empire (*see* TURKEY); its internecine troubles of the 17th and 18th centuries are outlined in the article DRUSES. It was the French invasion of Palestine in Feb. 1799 that brought the country once more under the full light of international concern. Napoleon Bonaparte sought to secure Syria as a bulwark in defense of his newly conquered Egypt and also as a base from which to threaten both Constantinople and the British power in India. The campaign (*see* FRENCH REVOLUTIONARY WARS), though abortive, was one that Napoleonic propaganda could represent as glorious: the memory of it made a lasting and fatal impression on the mind of the French public.

The French were deeply incensed at the convention of London (1840), when the other interested European powers agreed to Turkey's recovering the lost territories. Syrian rebellion and disputes of Syrian factions,

one of which was encouraged by the French, and the massacres of 1860 culminated in French intervention, and to the constitution of Lebanon as an autonomous province in 1864.

The Turkish revolution of 1908 gave impetus to the nationalist movement in the Arabic-speaking provinces of the empire, especially in Syria. The political demands of the Arabs, whose representatives met in June 1913 in Paris, involved a decentralization of the Turkish empire with administrative and cultural autonomy for the Arab provinces. The Syrian nationalists co-operated with similar movements in Mesopotamia and Egypt. During World War I the nationalist leaders entered into close contact with Faisal (*see* FAISAL I). The Turkish administration persecuted them: several were executed and regarded by their followers as martyrs of the movement of national liberation.

The French Mandate.—Faisal had meanwhile formed an Arab army, which fought together with the British under Lord Allenby. While the British conquered Palestine, the Arabs moved through Transjordan northward and by the end of 1918 had reached Damascus, where, according to the promises given to the Arabs during the war, an independent Arab government was set up under Faisal. But France, already holding Beirut and the coastal zone, desired a mandate over the whole of Syria, in spite of the fact that on Nov. 7, 1918, the British and French governments had jointly declared their intention of establishing in Syria and Mesopotamia "national governments drawing their authority from the initiative and free choice of the native populations." A Syrian national congress, however, elected Faisal king of Syria on March 11, 1920, appointed Hashim el-Atasi (1875–) as prime minister, and adopted on July 3 a democratic constitution for the whole of Syria, including Palestine and Transjordan; and in the summer of 1919 a United States commission found that the population rejected the idea of a French mandate. Nevertheless the French mandate was decided upon at San Remo on April 25, 1920, and Gen. Henri Gouraud, the French high commissioner, sent an ultimatum to Faisal demanding recognition of it in July. The Syrians rejected the demand, but their army under Yusuf al-Azmi was defeated at Khan Maisalun, the French entered Damascus, and Faisal left the country. The terms of the mandate were approved by the League of Nations on July 24, 1922.

The French established on Sept. 1, 1920, a state of the Lebanon. Its nucleus was the formerly autonomous sanjak with its predominantly Christian population; but the French incorporated into it districts with a predominantly Moslem population who protested against separation from the rest of Syria. Syria itself was further divided into four "states": the state of Damascus, the state of Aleppo, the state of the Jabal Druse and the state of the Alawis with the capital at Latakia. The sanjak of Alexandretta was made autonomous. Damascus and Aleppo, however, had soon to be united again in a state of Syria. Beirut was chosen as the seat of the French high commissioner. Paper constitutions were given to the different states, but real power remained in French hands. Discontent found expression in violent demonstrations.

The struggle for independence assumed a new form with the success of a local revolt in the Jabal Druse under the leadership of Sultan el-Atrash which broke out in July 1925. On Aug. 24 the Druses approached Damascus itself, where the nationalists quickly made common cause with them. A revolutionary government was established in the Jabal Druse with the help of the nationalist leader Abd ur-Rahman Shahbandar. The struggle lasted for many months, especially concentrated around Damascus but spreading to all parts of Syria, and subsided only in the summer of 1927. During this war Damascus was invaded by the nationalists on Oct. 18, 1925, whereupon the French bombarded the city for two days by artillery and from the air. The French promised eventually to grant Syria independence.

In 1928 the French abolished martial law, reintroduced certain civil liberties, asked Taj ud-Din el-Hasani to form a cabinet and, on March 10, announced elections for a constituent assembly. The elections in April brought an overwhelming victory to the nationalists, and on June 9 the assembly was opened in Damascus. Hashim el-Atasi was elected president of the assembly, and by August the draft of the constitution was ready. The assembly was finally dissolved in May 1930; but the Syrian constitution, with a transitional clause for the duration of the mandate, was proclaimed on May 14, 1930. It provided for a chamber of deputies elected for four years and for the election of a president of the Syrian republic for five years; every male citizen over 20 years of age had a vote. In the next six years the constitutional life of Syria went through several periods of storm and stress, caused by disagreements with the high commissioner, which led to a temporary suspension of parliamentary life. But in 1936 the growing tension in the Mediterranean and the example set by Great Britain in Egypt forced the French to adopt a more liberal attitude. A delegation under Hashim el-Atasi was invited to Paris, where on Sept. 9 a treaty was signed providing for a perpetual friendship between France and Syria. France was to be represented by an ambassador in Damascus, Syria by a minister plenipotentiary in Paris.

This treaty fulfilled many Syrian demands, except for that of union with Lebanon, with which the French concluded a separate treaty on Nov. 13, 1936. The Syrian parliament ratified the Franco-Syrian treaty on Dec. 26, 1936, but the French postponed ratification. Under an agreement between France and Turkey in Jan. 1937, the sanjak of Alexandretta (Iskenderun), which had a largely Turkish population, was to enjoy autonomy under the suzerainty of Syria; on Sept. 5, 1938, the legislative assembly of the sanjak assumed for the territory the Turkish name of Hatay; and on June 23, 1939, under Syrian protest, the territory was incorporated into Turkey.

Faced with strong opposition in parliament the French government announced on Dec. 14, 1938, that they did not intend for the present to ask parliament to ratify the Syrian treaty. The Syrian government and president resigned, and on July 10, 1939, the French high commissioner, Gabriel Puaux, suspended the constitution of 1930 and set up a directorate under his own control.

Gen. Eugène Mittelhauser, commander in chief in Syria, and Puaux declared on June 28, 1940, that they would cease hostilities against Germany and Italy and put themselves under the Vichy government. The Arab leaders first believed that Great Britain had been decisively defeated and that its empire would be inherited in the middle east by the Germans and the Italians. They sounded the intentions of the German armistice commission; but the successful resistance of the British and the defeat of the Italians in Africa deterred them from committing themselves prematurely. Abd ur-Rahman Shahbandar had been assassinated, yet the idea of a unified Arabia with Syria as its nucleus gained in strength.

The unsettled conditions, the scarcity and hoarding of food and the fast-rising prices for all commodities brought the Arab unrest into the open in a wave of widespread and often violent strikes which paralyzed communications. On March 20, 1941, the Syrian National party under Shukri el-Kuwatli (1891–) issued a manifesto in which it demanded the independence of the country. The revolt grew so violent that, after French troops had been used several times to quell riots, the French were forced again to try to meet the native demands halfway. In April 1941 they appointed Khalid el-Azam head of the Syrian government.

In May the Vichy government allowed German aircraft to land and refuel in Syria en route for Iraq (where hostilities had broken out between the British and a revolutionary pro-German government) and also supplied arms and ammunition to Iraq. At the end of the month the British foreign secretary, Anthony Eden, announced Great Britain's sympathy with Syrian independence and Arab unification. On June 8, British forces and Free French troops under Lieut. Gen. Sir Henry Maitland Wilson started military operations for the liberation of the Levant. It took them about a month to overcome the resistance of the French troops under Gen. Henri Dentz, high commissioner and commander in chief, appointed by the Vichy government in Dec. 1940. Damascus was occupied on June 21, and hostilities ceased on July 14. The food situation remained difficult until the 1942 harvest, but subsequently Syria became once more an exporter of grain, at highly inflated prices.

British troops were in Syria only for the purpose of winning the war, and the British were willing that France should enjoy a predominant position in an independent Syria. Gen. Georges Catroux, representative of the Free French in Syria, declared on Sept. 16, 1941, that "Free France, acting in agreement with her ally Great Britain, has undertaken to terminate the mandate and grant Syria the status of an independent sovereign state and to guarantee the new state by treaty." Pro-French Taj ud-Din el-Hasani was appointed president of the republic, but the nationalist leaders refused to take part in the government. In 1943 the French were persuaded by the British to allow elections to be held in the Levant states, and in Syria government of the National party was overwhelmingly returned under Shukri el-Kuwatli who, on Aug. 17, was elected president of the republic. In Feb. 1945 Winston Churchill met el-Kuwatli in Cairo and persuaded him to open negotiations with the French for a treaty comparable with the Anglo-Iraqi treaty of 1930. But in May Jean Helleu, the French high commissioner, returned with his government's proposals and his return coincided with the disembarkation of two small contingents of French troops. The Syrian and Lebanese governments felt that they would be negotiating under duress; and in any case the French proposals (based on the abortive treaty of 1936) were no longer compatible with their insistence on total independence. Disorders in the principal Syrian towns culminated in the French bombardment of Damascus by aircraft and heavy guns on May 29–30, causing about 500 Syrian deaths. The British government ordered their commander in chief in the middle east to intervene, the French troops were compelled to return to barracks, and French influence came to an end.

Independence.—Meanwhile in March 1945 the Syrian and Lebanese governments were invited to the United Nations conference at San Francisco, signifying their recognition as sovereign states. They appealed to the Security council to order the immediate withdrawal of French and British troops from their territories in Feb. 1946, and the evacuation of Syria was completed by April 15. The National party government was confirmed in power by elections in 1947; but discontent at its inefficient and allegedly corrupt administration was aggravated by the poor performance of the Syrian army in the Palestinian war of 1948, which gave rise to further political scandals. In Dec. 1948 student demonstrations forced the replacement of the government by a nonparty administration led by Khalid el-Azam. On March 30, 1949, this was overthrown and el-Kuwatli deposed by a bloodless coup d'état led by the chief of staff, Husni ez-Zaim, a

Kurd who for a few weeks seemed as if he might prove the long-hoped-for "saviour with a sword." As the political leaders were reluctant to commit themselves by serving under him, however, he sought support from the still-hated French and from Egypt and, rapidly quarrelling with all the neighbouring Arab governments, degenerated into an arbitrary despot. On Aug. 14 he was arrested and summarily shot by another military junta under Col. Sami Hinnawi. A general election in November returned a government of the People's party, opposed to the National party and favouring a closer union with Iraq; but this project was forestalled by a third military coup on Dec. 19, which removed Sami Hinnawi from power. New difficulties arose after Syria's denunciation of the customs union with Lebanon in March 1950. Internal disorders were prolonged by the assassination of the commander in chief of the air force, Mohammed Nasser, in July 1950. A new constitution was adopted on Sept. 6, 1950, and Hashim el-Atasi became president.

A new crisis arose when Great Britain, France, Turkey and the United States submitted their scheme for the middle east defense organization to the countries of the Arab league in Oct. 1951. Hasan Hakim, who had become prime minister in August, wanted to accept the plan and resigned in November because of cabinet opposition to it. After three weeks of crisis, Maruf ed-Dawalibi formed a cabinet, but was overthrown nine hours later by a coup d'état (Nov. 29) engineered by the chief of the general staff, Col. Adib esh-Shishakli. President Atasi resigned on Dec. 1, and the higher military council under Shishakli appointed Col. Fawzi Silo chief of state and prime minister.

Shishakli, as deputy premier and chief of staff, controlled the government. On June 21, 1953, he announced the end of the provisional regime under which Syria had been governed since Dec. 1951. A new constitution was accepted by a referendum held on July 10. On the same day Shishakli (now a brigadier general) was elected president of the republic, having received 86.6% of the votes cast. Shishakli's regime did not last long. In Jan. 1954 it was faced with political disturbances allegedly fomented by the Iraqi army leaders. Sultan el-Atrash, the old Druse leader, revolted in the Hauran and Syrian army dissidents joined the movement. On Feb. 25 Shishakli resigned and left the country, while the 79-year-old Atasi was restored as president of the republic, and the Shishakli constitution replaced by that of 1950. On Aug. 18, 1955, Shukri el-Kuwatli, who in 1949 had taken refuge in Saudi Arabia, was elected president for the third time.

In 1955 Syria was faced with the clash between Egypt and Iraq over the Baghdad defense treaty. It accepted an Egyptian invitation to participate in a new Arab defense treaty, to replace the Arab league collective security treaty of June 17, 1950, which, as the Egyptian government had declared, no longer existed. On Oct. 20, 1955, Syria signed a military treaty with Egypt which established a joint command, while Egypt undertook to finance 60% of Syria's additional military expenditure. (G. E. K.; X.)

Syria United With Egypt.—At the beginning of Nov. 1956 Kuwatli paid a state visit to Moscow. The principal result of this visit was the delivery to Syria of large consignments of Soviet arms and the arrival in Damascus of several hundred Soviet instructors and technicians. The Syrian leaders declared that this did not imply acceptance of Soviet domination or creed. Syria rejected, however, the Eisenhower doctrine for the middle east and declared that Israel, not communism, was the threat to peace and security in the area. In Aug. 1957 three officials of the U.S. embassy were accused of plotting to overthrow the Syrian government and had to leave the country. A month later an international crisis developed when Syria and the U.S.S.R., alleging that Turkey was massing troops near the Syrian frontier, accused the U.S. of plotting a revolution in Syria with Turkey and Shishakli.

On Feb. 1, 1958, Kuwatli and Gamal Abd-el-Nasser, president of Egypt, formally proclaimed the union of Egypt and Syria in a United Arab Republic (U.A.R.). Four days later the parliaments of both countries voted the provisional constitution of the U.A.R. On Feb. 21 this constitution was approved by plebiscites in both countries and, on the same day, Nasser was elected president of the U.A.R.

The Union Ended.—On Sept. 28, 1961, following an army coup, Syria seceded from the United Arab Republic. An independent government was established with Mamun Kuzbari as prime minister, and this government was recognized shortly afterward by leading powers. Diplomatic missions were re-established in Damascus. The Syrian Arab Republic rejoined the United Nations on Oct. 13 without any objection being raised. (X.)

POPULATION AND GOVERNMENT

In 1960 Syria covered an area of 71,227 sq.mi. (181,337 sq.km.). Most of the population is of Arab stock, the main national minorities being the Kurds and the Armenians. The Kurds, estimated in 1954 at 140,000, are grouped mainly in the north, along the Turkish frontier. The 120,000 Armenians (1954 est.) are settled in the towns, about 60,000 of them in Aleppo alone. The Alawis, a Moslem sect, form the majority in the province of Latakia; they are probably the indigenous inhabitants of the country. The most densely populated areas are situated around Damascus, Aleppo and Latakia. The desert, which lies east of the Aleppo-Damascus line is sparsely populated.

The country is divided into 12 provinces (*muhafaza*) (1960); Damascus (346,977), Damascus (city; 653,472), Homs (399,714), Hama (325,076), Latakia (524,246), Aleppo (956,561), Hazekeh (351,661), Dayr az Zawr (221,290), As Suwayda (99,512), Dar'a (167,049), Idlib (331,745), and Rashid (177,964), total: 4,555,267.

TABLE I.—*Distribution of the Population by Religion*

Religion	1943	1953
Moslems		
Sunnis	1,971,053	2,578,810
Shi'is	12,742	14,887
Druses	87,184	113,318
Alawis	325,311	398,445
Ismailis	28,527	36,745
	2,424,817	3,142,205
Christians		
Orthodox	136,957	168,747
Roman Catholic*	103,834	123,881
Armenian (Gregorian)	101,747	110,594
Syriac (Jacobite)	40,135	51,363
Chaldaean (Nestorian)	9,176	11,167
Protestant (all denominations)	11,187	13,209
	403,036	478,961
Jews	29,770	31,647
Others (mainly Yezidis)	2,788	3,091
Total	2,860,411	3,655,904

*Roman Catholic subdivides into six rites. The figures for 1943 (1953) were: Greek Melkite 46,733 (55,880); Syriac 16,247 (19,738); Armenian 16,790 (19,492); Maronite 13,349 (16,580); Latin 5,996 (6,749); Chaldean 4,719 (5,492).

The population of major towns (1960) was: Damascus (cap.) 529,579; Aleppo 425,029; Homs 136,474; Hama 110,809; Latakia 67,799.

Constitution.—The Syrian constitution of 1930, as revised in Sept. 1950, specifies that the president of the republic shall be a Moslem, elected by a majority in the chamber of deputies for a period of five years. The president should sign legislation passed by the chamber within three days or else refer it to the state council constitutionally established. Members of the chamber are elected by direct suffrage, and in the election to the constituent assembly in 1949, women voted for the first time. The electoral decree of that year provided for one deputy for every 30,000 electors, the electorate being limited to men of 18 years of age and women of the same age holding at least an elementary school certificate.

The president nominates the prime minister; the prime minister chooses the members of his cabinet.

The party system is not highly developed; political groups tend to form round prominent individuals rather than to follow a set policy, and there are many independents.

Defense.—In 1955 the armed forces numbered about 25,000 and included only one motorized brigade. There was also a *gendarmerie* 4,000 strong.

Education.—There has been a steady increase in the provision of educational facilities. After 1919 the language of instruction in all government schools was Arabic, though during the mandatory period the French were criticized for giving too much encouragement to the study of French and to French schools, of which there were a large number. After 1945 the Syrian government exercised stricter control over the curriculums of foreign schools, and the number of them was reduced.

The Syrian University of Damascus, founded in 1923 (7,696 students and a teaching staff of 267 in 1957–58), had schools of medicine and law and later established schools of arts, science and engineering. There are two agricultural colleges and a college of engineering at Aleppo. The Arab academy at Damascus, financed by the government, is a recognized centre for the study of Arab history and literature.

ECONOMY

Agriculture.—Agriculture is the main industry and supports more than 50% of the population. But the proportion of cultivable land is low (about 40%) and less than half of this was under cultivation in 1947. In 1954 about 60% of the cultivable land was being worked, an increase due to extension of the acreage under cereals and, especially, under cotton. During the ten years following World War II the irrigated area was extended more rapidly than the rain-fed area by

TABLE II.—*Agricultural Production*

(In thousands of metric tons)

Crop	1934–38	1948–50	1952	1953	1954

the development of projects for flow irrigation and by the installation of pumps, largely by private enterprise. The production of principal crops is shown in Table II. Of the many varieties of fruits grown, the

apricot, introduced to Syria since the earliest times, forms one of the principal crops.

Sheep and goats are the most important in animal husbandry;

TABLE III.—*Livestock*
(In thousands of head)

other animals are employed for farm work or transport (horses, mules, donkeys, oxen, camels). Goats as well as cattle are raised for their milk. (*See* Table III.)

Industry.—As in agriculture so in industry most of the post-World War I expansion was due to private enterprise though the government gave much protection and some financial assistance. The textile industry is by far the most important; cotton spinning began in 1933 and by 1939 there were 10,000 spindles. In 1954 there were about 92,000 spindles with a capacity of 12,000 tons of cotton and rayon yarn. Small factories produce 40 tons of woolen yarn and 16 tons of silk yarn. Mechanical looms increased from 1,500 in 1939 to 5,500 in 1953; there were also 6,000 hand looms.

Food processing was the industry next in importance. It included sugar refining, production of vegetable oils, canning of fruit and vegetables, and the manufacture of confectionery (preserved fruits, chocolate, etc.). Other industries produce glass, cement, soap, matches and leather.

In 1951 the government took over the concessions of the electricity companies and increased the output from 47,000,000 kw.hr. in 1947 to 114,000,000 kw.hr. in 1953.

A concession to prospect for oil in all Syria north of Damascus is held by the Syrian Petroleum company, one of the Iraq Petroleum company groups. Pipelines of the Iraq Petroleum company and the Trans Arabian company (a subsidiary of Aramco) cross Syria to Tripoli and Saida respectively.

Foreign Trade.—In 1950 the customs union with the Lebanon was terminated by Syria mainly through the desire of the Syrian government to protect its industries and agriculture. Agreements regulating trade between the two countries were concluded in 1952 and 1953. (*See* Table IV.)

TABLE IV.—*Foreign Trade**
(In millions of Syrian pounds, valued at the free rate)

	1951	1952	1953	1954	1955
Imports (c.i.f.)	304.0	313.3	307.0	408.1	676.9
Exports (f.o.b.)	277.1	319.6	375.8	465.7	473.5

*Including gold.

There was, in fact, a trade deficit inasmuch as the import figures given in the table had to be adjusted upward by about 45%, to take account of the divergence between the official exchange rate and the free rate at which imports actually took place. The deficit seemed to have been covered mainly by receipts from the oil companies.

In 1954 the main suppliers of imports were, in order of importance, the United States, the United Kingdom, France, the German Federal Republic, Lebanon and Italy; Syria's main customers were Lebanon, France, the Netherlands, the United Kingdom and the German Federal Republic.

Communications.—The railways of Syria are part of the Syro-Lebanese system belonging to a French company, the Chemins de Fer Damas-Hama et Prolongements (D.H.P.), sections of the "Baghdad" railway and a portion of the Hejaz railway from Damascus to Deraa (76 mi.). Passenger traffic on the internal lines is extremely light except on that from Rayak (Lebanon) to Aleppo. The total length of roads in Syria in 1953 was about 6,260 mi., of which 1,515 mi. were asphalted. Main roads are: (1) from Alexandretta along the coast to Beirut and the frontier of Israel; (2) Aleppo to Homs and thence by alternative roads to Damascus; (3) Damascus to Kuneitra and thence to the Israel frontier; and (4) Damascus to Suwaida and Deraa. Desert roads connect Aleppo with Deir ez-Zor and northeastern districts and Damascus with Palmyra and Deir ez-Zor. The main desert road from Damascus to Baghdad (540 mi.) passes through the Iraqi post at Rutbah wells.

The airport at Mezze (El Mazza) 5 mi. W. of Damascus is used by the main air lines serving the middle east.

After 1956 the port facilities at Latakia were greatly expanded with the construction of a 4,000-ft. mole and a 2,000-ft. main jetty capable of dealing with six vessels at a time, and the reclamation from the sea of about 4 ac.

Between 1945 and 1954 the traffic of merchandise through the harbour of Latakia rose from 11,000 metric tons to 837,000 tons, because of the diversion of trade from Beirut.

Finance.—The monetary unit is the Syrian pound (L.S.), the value of which, by a decree of April 20, 1949, was fixed at 405.512 mg. of pure gold, corresponding to 7.967 U.S. cents. From that date the Syrian currency was no longer linked to the French franc. The free

rate for the L.S. in Oct. 1955 was 4.634 U.S. cents. The currency in circulation in Dec. 1954 was about L.S. 360,000,000.

A budgetary surplus was recorded in every year of World War II and the reserve fund stood at L.S. 49,000,000 in 1945. A surplus of L.S. 8,000,000 was obtained in 1946. Table V shows revenue and expenditure from 1948 to 1955.

SYRIAC LANGUAGE, belongs to the Eastern Aramaic group of the Semitic languages (*q.v.*). Since the name "Aramaic" came to mean "pagan," the Greek name "Syrian" or "Syriac" was adopted by the inhabitants of that region. It was the language of Edessa, present day Urfa. Edessa became a centre of Christianity at the end of the 2nd century and the intellectual metropolis of the Christian orient. As a result, the neighbouring Aramaic Christians adopted Syriac. Since the 5th century A.D., because of theological differences, Syriac-using Christians have been divided into Nestorians, or East Syrians under the Persian sphere of influence, and Jacobite (Monophysites) or West Syrians under the Byzantine sphere. The Nestorians were excluded from Edessa and settled in Nisibis in Persia.

These two groups became linguistically distinguished by certain differences of pronunciation, chiefly in the vowels. Thus, the Jacobites have *ō* instead of *ā*, *i* and *e* became confused into *i*, whereas *ō* and *ū* both became *ū*. The script likewise became differentiated.

Writing.—The earliest Syriac inscriptions (on stone) belong to the first half of the 1st century A.D. and to the second half of the 2nd century. The earliest extant documents not inscribed on stone date from A.D. 243 and come from Dura Europos. The early Syriac script was an offshoot of a cursive Aramaic script. The script reads horizontally from right to left. The Syriac alphabet consists of twenty-two letters, all of them having consonantal values. The order of the letters in the alphabet is the same as in Hebrew, but the names of some of them are slightly different; thus, *alaph* (Syriac), *aleph* (Hebrew); *gamal* (Syriac), *gimel* (Hebrew); *semkath* (Syriac), *samek* (Hebrew). The majority of the Syriac letters have different forms depending upon their position in a word, whether at the beginning, middle or end, and whether they stand alone or joined to others. As in other Semitic languages, the consonants ' (*alaph*), *w* and *y* were originally employed to express vowel sounds.

A highly developed vocalic system was introduced in the beginning of the 8th century. Three main vowel systems developed using a combination of small Greek letters and of dots placed above and below the letters. The most important variety of the Syriac scripts is "estrangelo" derived probably from *satar angelo*, the "evangelic" writing. After the schism in the church, the Syriac language and script split into two branches. The western *serta* or *serto* ("linear") developed later into two varieties, the "Jacobite" and the "Melchite." The eastern branch, called Nestorian, had greater importance in the history of writing. When Arabic became the speech of daily life, it was sometimes written in Syriac script; the term for it is *karshuni* or *garshuni*, but its meaning is uncertain.

Phonology.—The consonant phonemes of Syriac are: labials *p, b, m, w;* dentals and sibilants *t, d, ṭ, š, s, z, ṣ;* liquids *l, n, r;* palatals and velars *k, g, q;* laryngeals ', *h, ḥ, ʿ*. The stops *b, p, d,*

t, g, k become spirant *b, p, d, t, g, k* if they are preceded by a vowel. The vowels are *a, ā, e, ē, i, ī, o, ō, u, ū,* and a very short *ĕ*. The diphthongs are *aw, ay, āy* (Western Syrian *ōy*), *ĕw, īw*. No syllable can begin with a vowel. All the consonants except *h, ʿ* and *r* can be geminated (or long) in medial position. Gemination does not occur either initially or finally. There is no gemination in Western Syriac.

A few cases of partial and total assimilation as well as of metathesis occurring with the morpheme *t* of the reflexive-passive stem should be mentioned here. Metathesis occurs in the combination *tš, ts* becoming *št, st;* thus *'eštamlī* for *'etšamlī* "it was accomplished," *'estĕged* for *'etsĕged* "he was worshipped." Metathesis and partial assimilation occur in *tz, tṣ* becoming *zd, ṣt;* thus *'ezdĕqĕp* for *'etzeqep* "he was placed upright," *'eṣṭĕleb* for *'etṣĕleb* "he was crucified." Total assimilation occurs in the succession *t-'* becoming *tt* and *t-d* becoming *dd;* thus *'ettaqtal* for *'et 'aqtal* "he was killed," *'eṭṭašše* for *'ettašše* "hide me," *neddakrak* for *netdakrak* "he remembers you." Likewise *n* as first radical of the root is assimilated to any consonant with which it is in contact: *'appeq* for *'anpeq* "he brought out."

Morphology.—Syriac has a set of independent personal pronouns used for the expression of the subject, and a set of shortened forms suffixed to the nouns and to the verbs. With the verb they express the direct complement, occasionally the indirect complement; with the noun, they express the possession. The forms of the nouns and of the verbs with the suffixed pronouns very often change their syllabic structure.

The noun has three states, an absolute, a construct and an emphatic state. The absolute state is the pure stem and is used mainly for adjectival and participial predicates. The construct state has as a rule the same form as that of the absolute state and is used in the expression of possession (*mĕlĕk ʿālmā* "the king of the world"). The emphatic state has the suffixed element *-ā* of the article, but lost its determined value so that *malkā,* originally "the king" came to mean "king."

There are two genders in Syriac, masculine and feminine. The mark of the feminine is the suffixed *-t*. Its form is *-aṯ* with a noun in the construct state (*bīš-aṯ*), *-ēṯā* with a noun in the emphatic state (*bīš-ēṯā*), and *-ā* in the absolute state (*bīš-ā*). Several noun classes (animals, plants, parts of the body, utensils) are treated as feminine without having the feminine ending *-t*.

Syriac has two numbers, singular and plural. The forms of the plural are: for the masculine, absolute state *-īn* or *-ēn* (*bīš-īn*), construct state *-āy* (*bīš-āy*), emphatic state *-āy(y)ā,* mostly contracted into *-ē;* for the feminine the forms are, absolute *-ān,* construct *-āṯ,* emphatic *-āṯā*.

The Verb.—There are biradical, triradical and quadriradical verbs, the majority being triradicals. The basic stem of the regular triradical verb has the forms *qĕtal* (mostly transitive), and *qĕtel* (mostly intransitive). The verbs that have a first radical *w, y, n* or laryngeals as 1st, 2nd or 3rd radical have different syllabic structures in the various tenses of the verb. The biradicals are of the types *qām, baz*(*z*) and *rĕmā,* whereas the quadriradicals have the form *qartel*. The derived stems are *qattel* (with geminated 2nd radical) serving mainly for the expression of the intensive (occasionally causative) and *'aqtel* (with the prefix *'a-*) for the causative. All these stems can form a passive-reflexive mood with the prefixed morpheme *'eṯ,* the forms being *'eṯqtel* (from *qtal, qtel*), *'eṯqattal* (from *qattal*) and *'ettaqtal* (from *'aqtel*).

There is a considerable number of Syriac verbs having the prefix *ša-* (*šaqtel*) for the expression of the causative, and *qatqat* (that is, a repeated biradical root) for the expression of the frequentative.

The past is expressed by the "perfect" which is formed by suffixed morphemes (thus, **kĕtab* "he wrote," **kĕtabū* "they wrote"). Habitual or continuous action in the past is expressed by the active participle followed by the perfect of *hĕwā* "he was" (thus *dāḥel hĕwā* "he was fearing"). The future is expressed by the "imperfect" formed by prefixes or suffixes or both (thus, **nektūb* "he will write," *nektĕbūn* "they will write"). The present is expressed by the active participle followed by the personal pronoun, mostly in contracted form (thus **kāteb 'at* or **kātbat* "you write").

The expression for the 1st person is common for the masculine and feminine, whereas for the 2nd and 3rd persons there are special forms for the masculine and feminine. Note that the prefix of the imperfect 3rd person is *n* against *y* of the other Aramaic dialects.

Like all the other Semitic languages Syriac has no verb "to have." The idea of possession is expressed by the verb *'īṯ* "there is, there are" followed by the indirect complement (thus *kĕmā laḥmīn 'iṯ lĕkūn* "how many loaves of bread do you have?" literally "how-many breads there-are to-you?").

The Syriac vocabulary is basically Semitic. Among the loanwords are some Hebrew words in the domain of religion and some Persian words from translations of Persian, but the great majority of loanwords are Greek.

(W. Lu.)

SYRIAC LITERATURE. The use of Syriac by Christians as a literary medium had its original centre in Edessa (Syr. Ūrhāi, modern Urfa), where, in all probability, the chief Syriac versions of the Bible were made. The use of the same dialect appears in the earliest Christian literature connected with such Mesopotamian cities as Nisībis, Amid, Mardīn, Taghrīth and Seleucia-Ctesiphon, as well as west of the Euphrates at such centres as Mabbōgh (Hierapolis) and Aleppo, northward at Malaṭiah and Maiperkat and in the districts of Lake Van and Lake Urmia, and to the east and southeast of the Tigris in many places which from the 5th century onward were centres of Nestorian Christianity within the Sassanian empire.

In Palestine and western Syria, the home of pre-Christian Aramaic dialects, the vernacular Semitic speech had under Roman dominion been replaced by Greek for official and literary purposes. Apparently this state of things lasted till after the Mohammedan conquest, for Barhebraeus tells us that it was the caliph Walid I. (A.D. 705–715) who, out of hatred to Christianity, replaced Greek by Arabic as the language of official documents at Damascus.

Syriac literature continued in life from the 3rd to the 14th century A.D., but after the Arab conquest it became an increasingly artificial product, for Arabic gradually killed its vernacular use.

Religious Literature.—In the literature as it survives many different branches of writing are represented—homilies in prose and verse, hymns, exposition and commentary, liturgy, apocryphal legends, historical romance, hagiography and martyrology, monastic history and biography, general history, dogmatics, philosophy and science, ecclesiastical law, etc. But the whole is dominated by the theological and ecclesiastical interest. When we put aside one or two exceptionally fine pieces, like the hymn of the soul in the apocryphal Acts of Thomas, the highest degree of excellence in style is perhaps attained in straightforward historical narrative—such as the account of the Perso-Roman War at the beginning of the 6th century by the author who passes under the name of Joshua the Stylite, or by romancers like him who wrote the romance of Julian; by biographers like some of those who have written lives of saints, martyrs and eminent divines; and by some early writers of homilies such as Philoxenus (in prose) and Isaac of Antioch (in verse).

For the general history of culture the work of Syriac writers as *translators* is, perhaps, as important as any of their original contributions to literature. Beginning with the earliest versions of the Bible, which seem to date from the 2nd century A.D., the series comprises a great mass of translations from Greek originals—theological, philosophical, legendary, historical and scientific. In a fair number of cases the Syriac version has preserved to us the substance of a lost original text. Often, moreover, the Syriac translation became in turn the parent of a later Arabic version. This was notably the case with some of the Aristotelian writings,

so that in this field, as in some others, the Syriac writers handed on the torch of Greek thought to the Arabs, by whom it was in turn transmitted to mediaeval Europe. The early Syriac translations are in many cases so literal as to do violence to the idiom of their own language; but this makes them all the more valuable when we have to depend on them for reconstructing the original texts. The later translators use greater freedom. It was not from Greek only that translations were made into Syriac. Of translations from Pahlavī we have such examples as the version of pseudo-Callisthenes' *History of Alexander,* made in the 7th century from a Pahlavī version of the Greek original—that of *Kalilah and Dimnah* executed in the 6th century by the perioudeutēs Bōdh—and that of *Sindbad,* which dates from the 8th century; and in the late period of Syriac literature, books were translated from Arabic into Syriac as well as vice versa.

The Cradle of Syriac Literature.—All our historical sources support the view taken above that Edessa, the capital of the kingdom which the Greeks and Romans called Osrhoene, was the earliest seat of Christianity in Mesopotamia and the cradle of Syriac literature. But as to the date and circumstances of its evangelization we have little reliable information. The well-known legend of the correspondence of Abgar Ukkāmā, king of Edessa, with Christ and the mission of Addai to Edessa immediately after the Ascension was accepted as true by the historian Eusebius (d. 340) on the faith of a Syriac document preserved in the official archives of the city. An amplified form of the same story is furnished by the *Doctrine of Addai,* an original Syriac work which survives complete in a St. Petersburg (Leningrad) ms. of the 6th century, and is also represented by fragments in other mss. of the 5th and 6th centuries. This work was probably written at Edessa about the end of the 4th century. But whether in its longer or its shorter form, the whole narrative must be pronounced unhistorical. In all probability the first king of Osrhoene to adopt Christianity was Abgar IX., son of Ma'nū, who reigned from A.D. 179 to 214 or 216, and the legend has confounded him with an earlier Abgar, also son of Ma'nū, who reigned first from B.C. 4 to A.D. 7 and again from A.D. 13 to 50. (*See* Lipsius, *Die edessenische Abgar-Saga,* 1880.) A contemporary of Abgar IX. at Edessa was the famous Bardaiṣān, himself a convert from heathenism, who was of noble birth and a *habitué* of the Edessene court. It was no doubt partly under his influence—also possibly in part through impressions received by Abgar during his visit to Rome about A.D. 202—that the king's conversion took place. But Christianity must have reached Edessa some 30 to 50 years earlier. Our oldest native historical document in Syriac—the account of a severe flood which visited Edessa in Nov. A.D. 201—mentions "the temple of the church of the Christians" as overthrown by the flood.[1] The form of this notice shows, as von Gutschmid and others have remarked, that Christianity was not yet the religion of the State; but it must for some time have had a home in Edessa. By a skilful piecing together of the data furnished by the oldest Syriac versions of the Bible—such as the derivation of the Old Testament version from the Jews, and the almost exclusive use of Tatian's Diatessaron as the gospel of the Syriac Church down to the beginning of the 5th century—F. C. Burkitt has shown it to be probable that the preaching of Christianity at Edessa reaches back to the middle of the 2nd century or even to about the year 135 (*Early Eastern Christianity,* Lecture II.).

The Syriac versions of the Bible are treated elsewhere (*see* BIBLE) and may here be dismissed with a brief summary of facts and opinions. The received Syriac Bible or Vulgate (called the Peshitta or "simple" version from the 9th century onwards) contains all the canonical books of the Old Testament. In the New Testament, 2 Peter, 2 and 3 John, Jude and the Apocalypse were originally left out, but Syriac versions were made at a later time. The Peshitta version of the Old Testament must have been originally made mainly by Jews, of whom we know there were colonies in Mesopotamia in the 2nd century. The translation was executed entirely from the Hebrew, but underwent later revision which brought it more into conformity with the LXX.—this to a greater degree in some books than in others. The Peshitta New Testament—according to the convincing theory which at present holds the field—is not the oldest form of the Syriac version, at least as regards the Gospels. From the beginning of the 3rd to the beginning of the 5th century Tatian's Harmony or Diatessaron —whether originally compiled in Syriac, or compiled in Greek and translated into Syriac—was the current form of gospel in the Syriac Church. The text of the Gospels underlying it "represents the Greek text as read in Rome about A.D. 170." Slightly later was made the Old Syriac version of the separate Gospels, which survives in two mss.—the Curetonian and the Sinaitic—in two differing forms: but this never obtained much currency. Its text "represents, where it differs from the Diatessaron, the Greek text as read in Antioch about A.D. 200." Then at the beginning of the 5th century, by the efforts of the masterful Rabbūlā, who was bishop of Edessa from 411–412 to 435, a new version or recension of the Gospels was made and incorporated in the Peshitta or Vulgate, the use of the Diatessaron being henceforth proscribed. Rabbūlā's text of the Gospels "represents the Greek text as read in Antioch about A.D. 400." The history of the Peshitta rendering of the Acts and Epistles is less clear.

Apocryphal Books.—Of the large number of Apocryphal books existing in Syriac the majority have been translated from Greek, one or two (such as *Bar Sira* or *Ecclesiasticus*) from Hebrew, while some (like the *Doctrine of Addai* above referred to) are original Syriac documents. Special mention may be made here of the tale of Aḥīḳār—the wise and virtuous secretary of Sennacherib, king of Assyria—and of his wicked nephew Nādhān. This is the Syriac version of a narrative which has had an extraordinary vogue in the world's literature. It is now known to have existed in Aramaic as far back as the 5th century B.C., appearing in Jewish papyri which were lately discovered by the German mission to Elephantine. It appears to be traceable in its Greek dress in writings of the philosopher Democritus and the dramatist Menander; it was certainly known to the author of Tobit and perhaps to the author of Daniel; some would trace its influence in the New Testament, in the parable of the wicked servant and elsewhere; it was known to Mohammed and is referred to in the Koran; it has been included among the tales in the *Arabian Nights;* and it survives in a good many versions ancient and modern. The old Syriac version, which is to be found in a number of mss., was probably made from an early Aramaic version, if not from the original itself (which must surely have been Semitic). The Syriac has in turn become the parent of the Arabic, Armenian and Ethiopic—possibly also of the Greek and Slavonic-versions. (*See* F. Nau, *Histoire et sagesse d'Ahikar l'Assyrien,* 1909.)

Another deeply interesting Syriac Apocryphon is the *Acts of Judas Thomas* (*i.e.,* Judas the Twin), which is included in the collection of *Apocryphal Acts of the Apostles.* The *Acts of Thomas* is now generally recognized to be an original Syriac work (or "novel," as Burkitt calls it), although a Greek version also exists. It seems to have arisen in Gnostic circles, and its tendency is wholly in favour of asceticism and celibacy. Among its peculiarities is the fact that Judas Thomas is regarded as the twin brother of Christ. The author has incorporated in it the finest poem to be found in all Syriac literature, the famous Hymn of the Soul.

Lives of the Saints.—Lives of saints and martyrs form a large group among Syriac books. Among such documents connected with the early history of Edessa we have, besides the *Doctrine of Addai,* certain martyrdoms, those of Sharbēl and Barsamyā assigned to the reign of Trajan, and those of Guryā and Shāmōnā and of the Deacon Habbībh under Diocletian and Lincinius. All these documents, like *Addai,* belong probably to the 2nd half of the 4th century, and are unreliable in detail for the historian though they may throw some light on the conditions of life at Edessa under Roman government. There are also accounts of martyrdoms at Samosāta (Assemani, *Acta Mart.* ii. 123–147), including that of St. Azazail published by Macler (Paris, 1902). But the great bulk of the Syriac martyrdoms have their scene farther east, within the Persian dominions.

The life and writings of Bardaiṣān, "the last of the gnostics," and in some sense the father of Syriac literature and especially of Syriac poetry, have been treated in a separate article. *The Book of the Laws of the Countries,* which embodies his teaching

was re-edited in 1907 by F. Nau (this also in the 2nd volume of Graffin's *Patrologia*). Mention may here be made of the valuable edition and translation by the late C. W. Mitchell of *S. Ephraim's prose refutations of Mani, Marcion and Bardaisan. Transcribed from the palimpsest B. M. Add. 14628* (1912–21).

An early Syriac document, probably of the 2nd or 3rd century, is the *Letter of Mārā son of Serapion*, which was edited by Cureton in his *Spicilegium Syriacum*. It is almost the only exception to the rule that all surviving Syriac literature is Christian.

By the beginning of the 4th century much progress had been made with the organization of the Christian church not only within the Roman district of Mesopotamia, but also to the east and south-east within the Sassanian empire, round such centres as Seleucia-Ctesiphon on the Tigris (near Baghdad), Karkā dē-Bēth Sēlōkh (modern Kerkuk) and Bēth Lāpāt or Gundēshābhōr (in the modern province of Luristan). The adoption of Christianity by Constantine as the official religion of the Roman empire had an unfortunate effect on the position of the Christians in Persia. They were naturally suspected of sympathizing with the Roman enemies rather than with their own Persian rulers. Accordingly when Sapor II. (310–379) declared war on Rome about 337, there ensued almost immediately a somewhat violent persecution of the Persian Christians, which continued in varying degrees for about 40 years. One result of this and later persecutions of the same kind has been to enrich Syriac literature with a long series of *Acts of Persian Martyrs*, which, although in their existing form intermixed with much legendary matter, nevertheless throw valuable light on the history and geography of western Persia under Sassanian rule.

4th and 5th Centuries.—The two most important 4th-century writers—Aphraates and Ephraim—are dealt with in separate articles. The importance of the former lies in the simple cast of his religious thought, his independence of theological formulas, his constant adherence to the letter of Scripture, his quaint exegesis, and the light he throws on the circumstances of his time, especially (1) the feeling between Jews and Christians, and (2) the position and sympathies of the Christian subjects of Sapor II. The position and character of Ephraim are very different. He is the typical exponent in Syriac of unbending Catholic orthodoxy.

Before leaving the 4th century we may mention two other writers who probably both lived on into the 5th—Balai and Cyrillōnā. The former was the author of a good many poems; the longest—which is however by some attributed to Ephraim—is the work in 12 books on the history of Joseph, of which a complete edition was published by Bedjan in 1901. Other poems of his were edited by Overbeck in *S. Ephraemi Syri*, etc., *opera selecta*, pp. 251–336; and these have since been supplemented by Zetterstéen's edition of a large number of his religious poems or metrical prayers (*Beiträge zur Kenntniss der religiösen Dichtung Balais*, Leipzig, 1902). His favourite metre was the pentasyllabic. Cyrillōnā composed a poem on the invasion of the Huns in 395.

The 5th century was a time of storm and conflict in the churches of Mesopotamia and Persia, as in other parts of the Christian world. The teaching of Apollinarius that in Christ the Divine Word took the place of the human rational soul, thus seeming to do away with his possession of a true humanity, had led to a reaction by Paul of Samosāta, Diodore of Tarsus, Theodore of Mopsuestia, and Nestorius of Constantinople. Though with some points of difference, they agreed in emphasizing the permanence of the two separate natures in Christ, united but not mingled or confused, and laid stress on the reality of our Lord's human experience. One question on which great contention arose was as to the propriety of applying to the Divine nature attributes which belonged to the human nature—*e.g.*, birth from a human mother—and vice versa. Hence the great dispute about the application to the Virgin Mary of the epithet *θεοτόκος*. It seems to have been the objection of Nestorius to the use of this expression which mainly led to his condemnation and deposition at the Council of Ephesus (431) under the influence of Cyril, although as patriarch of Constantinople (428–431) he had distinguished himself by his zeal for Nicene orthodoxy. New light on the theological position of Nestorius is to be obtained from the long-lost *Book of Heraclides*, a work of his own which has turned up in a Syriac version and was published by Bedjan in 1910.

At Edessa the result of the conflict between the Nestorians and their opponents was long doubtful. When Rabbūlā, the fierce anti-Nestorian and friend of Cyril, died in 435, he was succeeded in the bishopric by Ibas, who as head of the famous "Persian school" in the city had done much to inculcate on his pupils the doctrines of Theodore of Mopsuestia. But the feeling against the Nestorian party grew in strength, till on the death of Ibas in 457 the leading Nestorian teachers were driven out of Edessa. The Persian school continued to exist for another 32 years, but was finally closed and destroyed by order of the emperor Zeno in 489. The Nestorian teachers then started a great school at Nisībis (which had been under Persian rule since Jovian's humiliating treaty of 363). By the energetic efforts of Barṣaumā, bishop of that city, practically the whole church of Persia was won over to the Nestorian creed.

Great Churchmen.—At the beginning of the 5th century one of the most able and influential men in the Syriac-speaking Church was Mārūthā, bishop of Maiperḳaṭ or Martyropolis. Without entering on the details of his ecclesiastical activity, we may note that he was twice associated with embassies from the Roman emperor to Yazdegerd I. (399–420); that along with Isaac, patriarch of Seleucia (390–410), he obtained from the Persian monarch a concordat which secured a period of religious toleration; and that he arranged for and presided at the Council of Seleucia in 410, which adopted the full Nicene creed and organized the hierarchy of the Persian Church. As a writer he is chiefly known as the reputed author of a collection of martyrologies which cover the reigns of Sapor II., Yazdegerd I. and Bahram V. By his history of the Council of Nicaea he made a great contribution to the education of the Persian Church in the development of Christian doctrine.

The next bishop of Edessa, Ibas, who succeeded in 435 at the death of Rabbūlā, proved himself a follower of the Nestorian doctrine. (*See* above.) As a teacher in the Persian school of Edessa he had translated, probably with the help of his pupils, certain works of "the Interpreter," *i.e.*, Theodore of Mopsuestia. Among these may have been the commentary on St. John of which the complete Syriac version was published by Chabot in 1897. He may possibly have translated a work of Aristotle. To the Nestorian movement in Persia he rendered useful service by his letter to Mārī of Bēth Hardashēr, in which he maintained the tenets of Diodore and Theodore, while allowing that Nestorius had erred. On the ground of his writings he was condemned and deposed by the "robber synod" of Ephesus (449), but was restored by the Council of Chalcedon (451), after he had anathematized Nestorius. His death in 457 was followed by a strong anti-Nestorian reaction at Edessa, which led to the expulsion of many of the leading teachers.

On Isaac of Antioch, "one of the stars of Syriac literature," *see* the special article. In spite of his over-diffuseness, he is one of the most readable of Syriac authors.

A Nestorian contemporary of Isaac, Dādhīshō', who was catholicus of Seleucia from 421 to 456, composed commentaries on Daniel, Kings and Ecclesiasticus. His chief importance in the history of the Persian Church lies in his having induced a synod of bishops to declare that church independent of the see of Antioch and of the "Western Fathers." (*See* J. Labourt, *Le Christianisme dans l'empire perse*, 1904, p. 122 *seq.*)

The most powerful missionary of Nestorianism during the 2nd half of the 5th century was Barṣaumā of Nisībis, whom his opponents called "the swimmer among the reeds," *i.e.*, the wild boar. Born probably between 415 and 420 he imbibed Nestorian doctrine from Ibas at the Persian school of Edessa, but was driven out in 457 on the death of his master, and went to be bishop of Nisībis. In a succession of missionary journeys he succeeded, partly by persuasion and partly (if his enemies are to be believed) by violence, in attaching to Nestorianism nearly all the Christian communities of Persia, with the exception of Taghrīth, which was always strongly Monophysite. He had many quarrels with

his ecclesiastical superior the catholicus of Seleucia, but finally made peace with Acacius soon after the accession of the latter in 484. Among other severities towards the Monophysites, he persuaded the Persian king Pērōz (457–484) to banish many of them into the Roman dominions. One of his great aims was to secure for the Nestorian clergy freedom to marry, and this was finally sanctioned by a council at Seleucia in 486 (Labourt, *op. cit.*, chap. vi.). Barṣāumā must have been bishop of Nisībis for nearly 40 years, but was dead by 496. His writings seem to have been chiefly liturgical; he gave the first set of statutes to the school of Nisībis, which was founded during his bishopric.

His fellow-worker Narsai, whom the Jacobites called "the leper," but the Nestorians "the harp of the Holy Spirit," apparently accompanied Barṣāumā from Edessa to Nisībis, where according to Barhebraeus he lived for 50 years. Barṣāumā appointed him head of the new school, where he taught rigidly Nestorian doctrine. He was a copious writer, especially in verse. Many of his poems have now been published. (*See* Mingana, *Narsai, homiliae et carmina*, 2 vols. Mosul, 1905.) His theological position is clearly defined in a homily on the three doctors —Diodore, Theodore and Nestorius—published by the Abbé Martin in the *Journal asiatique* for July 1900.

To about the same period belongs *The book of Hierotheus* by the "pantheist" Stephen bar Sūdh-aite, which has recently been edited and translated by F. C. Marsh (1927).

Early Monophysites.—Among the early Monophysites were two of the best of Syriac writers—Jacob of Sērūgh and Philoxenus of Mabbōgh, who have been treated in special articles. The one wrote mainly in verse, the other in prose. *See* also JOSHUA THE STYLITE.

Another early Monophysite was Simeon of Bēth Arshām, who by a series of journeys and disputations within the Persian empire did all he could to prevent the triumph of Nestorianism among the Persian Christians. He had considerable success at the time, but the ground he had won was soon reconquered by his opponents, except at Taghrīth and the surrounding district. It was after a successful disputation in presence of the Nestorian catholicus Bābhai (497–502/3) that Simeon was made bishop of Bēth Arshām, a town near Seleucia. He made several journeys to Constantinople, where he enjoyed the favour of the empress Theodora. It was there he died, probably about 532–533. His biography was written by John of Asia in the collection of lives of eastern saints which has been edited by Land (*Anecd. syr.* vol. ii.). His literary productions consist only of a liturgy and two exceedingly interesting letters. The one has for its subject Barṣāumā and the other Nestorian leaders in Persia, and gives a highly malicious account of their proceedings. The other, which has been often edited, is an account of a severe persecution which the Himyarite Christians of Najrān in south-west Arabia underwent in 523, at the hands of the king of Yemen. (See *The book of the Himyarites*, a Syriac work edited and translated by A. Moberg, Lund, 1924.) As Simeon had repeatedly visited al-Ḥīrah and was in touch with the Arab kingdom which centred there, his letter is a document of first-rate historical importance.

Mention should be made of two other early Monophysite leaders who suffered persecution at the hands of the emperor Justin I. (518–527). The one, John of Tellā, author of 538 canons, answers to questions by the priest Sergius, a creed and an exposition of the Trisagion. His life was written by his disciple Elias, and also by John of Asia. The other, John bar Aphtōnyā, was the founder of the famous monastery of Kenneshrē, opposite Jerābīs on the Euphrates, and wrote a commentary of the Song of Songs, a number of hymns and a biography of Severus, the Monophysite patriarch of Antioch (512–519).

The life of the great missionary bishop Jacob Burdĕ'ānā or Baradaeus, from whom the Monophysite Church took its name of Jacobite, belongs rather to ecclesiastical than to literary history. (*See* H. G. Kleyn, *Jacobus Baradaeus, de Stichter der Syrische monophysietische Kerk*, Leyden 1882.)

Translators from the Greek.—In Sergius of Rās'ain we find one of the best Greek scholars and ablest translators whom Syria has produced. Of his life little is known, and that little not wholly creditable. He wavered curiously in his ecclesiastical views, and ended by helping the persecutors of the Monophysite Church, to which he himself had belonged. He seems to have lived as a priest and physician at Rās'ain in Mesopotamia most of his life. About 535 he travelled on various ecclesiastical missions, and finally made a journey to Rome and thence to Constantinople (in this latter accompanied by the pope Agapetus). The result was to bring about the deposition and banishment of the Monophysites from the latter city. Sergius died almost immediately afterwards, in 536. Among the works which he translated into Syriac and of which his versions survive are treatises of Aristotle, Porphyry and Galen, the *Ars grammatica* of Dionysius Thrax, the works of Dionysius the Areopagite, and possibly two or three treatises of Plutarch. His own original works are less important, but include a "treatise on logic, addressed to Theodore (of Merv), which is unfortunately imperfect, a tract on negation and affirmation; a treatise, likewise addressed to Theodore, *On the Causes of the Universe, according to the Views of Aristotle, showing how it is a Circle;* a tract *On Genus, Species and Individuality;* and a third tract addressed to Theodore, *On the Action and Influence of the Moon, explanatory and illustrative of Galen's* Περὶ κρισίμων ἡμερῶν, bk. iii., with a short appendix 'On the Motion of the Sun' " (Wright). According to the historical compilation which passes under the name of Zacharias Rhetor, he also wrote a treatise on the faith. Some of his translations were revised at a later time by Honain ibn Iṣḥāḳ (d. 873).

Another translator from Greek was Paul, Monophysite bishop of Callinīcus or ar-Raḳḳah, who, being expelled from his diocese in 519, retired to Edessa and there occupied himself in translating into Syriac the works of Severus, the Monophysite champion who was patriarch of Antioch from 512 to 519. This version appears to be quite distinct from that used by the compiler of the chronicle of Zacharias, and also from the version of "the 6th book of the select letters of Severus" which was made by Athanasius "presbyter of Nisībis" in 669, edited by E. W. Brooks (1902–04).

That important legal work, *The Laws of the Emperors Constantine, Theodosius and Leo*, which was composed in Greek about 475, and "which lies at the root of all subsequent Christian oriental legislation in ecclesiastical, judicial and private matters" (Wright), must have been repeatedly translated into Syriac. The oldest form is contained in a British Museum ms. which dates from the earlier part of the 6th century, and this was edited by Land (*Anecd. syr.* i. 30–64). A later (probably Nestorian) recension is contained in a Paris ms., which was used along with the other by Bruns and Sachau in their exhaustive edition (*Syrisch-römisches Rechtsbuch*, Leipzig, 1880). In *Notulae syriacae* (privately printed 1887) Wright edited the surviving fragment of a 3rd recension which is preserved in a 13th-century ms. at Cambridge. Finally Sachau has published three new redactions of the treatise from a ms. found at Rome in 1894 (*Syrische Rechtsbücher*, vol. i., Leipzig, 1907).

Anonymous Works.—We may here take note of three important anonymous works, of which the first probably and the other two certainly belong to the 6th century.

The Mĕ'arrath gazzē or *Cave of Treasures*, translated and edited by C. Bezold (Leipzig, 1883–88), is akin (as Duval remarks) to the *Book of Jubilees*. It is an imaginary history of the patriarchs and their descendants.

The tripartite narrative which is known as the *Romance of Julian* (the Apostate) has no claim to be regarded as an historical document. Its hero is Jovian, one of the feeblest of Roman emperors, and Julian is everywhere exhibited in flaming colours as the villain of the story.

A valuable historical source, though of small dimensions, is the *Chronicle of Edessa*, which gives a record of events from 132–131 B.C. to A.D. 540—at first exceedingly brief, but becoming somewhat fuller for the later years. It appears to be thoroughly reliable wherever it can be tested. It has been three times edited—first by Assemani in the *Bibliotheca orientalis* (i. 388–417), secondly by L. Hallier (Leipzig, 1892) with a translation, introduction and abundant notes, and thirdly by Guidi with a Latin version

(in *Chronica minora*, Paris, 1903).

On John of Asia or Ephesus, the eminent Monophysite bishop and earliest Syriac church historian, *see* the separate article.

An historical work of somewhat similar character to John's is the compilation in 12 books which is generally known by the name of Zacharias Rhetor, because the anonymous Syriac compiler has incorporated the Syriac version or epitome of a lost Greek history written by that author. The Syriac work exists (not quite complete) in a British Museum ms. of about the beginning of the 7th century: this can be in part supplemented by an 8th-century ms. at the Vatican. From the latter Guidi published the interesting chapter (X. 16) which contains the description of Rome. The entire text of the London ms. was published by Land in the third volume of his *Anecdota syriaca;* and there is now an English translation by Hamilton and Brooks (1899), and a German one by Ahrens and Krüger (Leipzig, 1899).

Of the other 6th-century Jacobite writers we need mention only Moses of Aggēl (*fl. c.* 550–570) who translated into Syriac some of the writings of Cyril, and Peter of Callinīcus, Jacobite patriarch of Antioch 578–591, who wrote a huge controversial treatise in 4 books, each of 25 chapters, against Damian, patriarch of Alexandria, as well as other less important works.

The Nestorian writers of the 6th century were numerous, but as yet we know little of their works, beyond what 'Abhdīsho' tells us in his *Catalogue*. It will be sufficient to mention one or two. Joseph Hūzāyā (*i.e.*, of al-Ahwāz or Khūzistan), who came third in succession to Narsai as head of the school of Nīsībis, was the first Syriac grammarian and invented various signs of interpunction. Mārūthā, who was Nestorian catholicus of Seleucia from about 540 to 552 (*see* Labourt, *op. cit.*, pp. 163–191), and a man of exceptional energy, made the only known attempt, which was, however, unsuccessful, to provide the Nestorians with a Bible version of their own. He was the author of many commentaries, homilies, epistles, canons and hymns. Paul the Persian, a courtier of Khosrau Anōsharwān, dedicated to the king a treatise on logic which has been published from a London ms. by Land in the 4th volume of his *Anecdota*. Bōdh the periodeutes is credited with a philosophical work which has perished, but is best known as the author of the old Syriac version of the collection of Indian tales called *Kalīlah and Dimnah*. He made it doubtless from a Pahlavī version. His translation, which was edited by Bickell with an introduction by Benfey, must be distinguished from the much later Syriac translation made from the secondary Arabic version and edited by Wright in 1884, of this there is an English translation by Keith Falconer (1884). Ḥannānā of Ḥědhaiyabh, who nearly produced a disruption of the Nestorian Church by his attempt to bridge over the interval which separated the Nestorians from Catholic orthodoxy, was the author of commentaries.

Decay in the 7th Century.—"With the 7th century," as Wright remarks, "begins the slow decay of the native literature of the Syrians, to which the frightful sufferings of the people during the great war with the Persians in its first quarter largely contributed." The same process of decay was greatly promoted by the Arab conquest of Persia, achieved through the victory of Ḳādisīya in 636–637. The gradual replacement of Syriac by Arabic as the vernacular language of Mesopotamia by degrees transformed the Syriac from a living to a dead language. Apart from a few leading writers—such as Jacob of Edessa, the anonymous historian whose work has passed under the name of Dionysius of Tell-Maḥrē, Thomas of Margā, Dionysius bar Ṣalībī, and Barhebraeus (*qq.v.*)—there are few names of interest.

1. *Theology.*—Here we may first mention George, bishop of the Arabs (d. 724), who wrote commentaries on Scripture, and tracts and homilies on church sacraments, and finished the *Hexaēmeron* of Jacob of Edessa. Bābhai the Elder, a leading Nestorian in the beginning of the 7th century and a prolific author, wrote many commentaries and theological discourses. Īshō'yabh III., Nestorian catholicus from 647 to 657/8, wrote controversial tracts, religious discourses and liturgical works. Elias of Merv, who belongs to the 2nd half of the 7th century, compiled a *Catena patrum* on the Gospels and wrote many commentaries. Timothy I., catholicus 779–823, wrote synodical epistles and other works bearing on church law. Moses bar Kēphā (d. 903), one of the most fertile of 9th-century authors, wrote commentaries, theological treatises and many liturgical works. Other important contributors to this sphere of literature were Īshō' bar Nōn (d. 827/8), John bar Zō'bī (beginning of the 13th century), Jacob bar Shakkō (d. 1241), and the great Nestorian scholar 'Abhdīshō' (d. 1318).

2. *History.*—Besides the important writers treated in separate articles, we need mention only four. Elias bar Shīnāyā, who in 1008 became Nestorian bishop of Nisībis, was the author of a valuable *Chronicle*, to which are prefixed numerous chronological tables, lists of popes, patriarchs, etc., and which covers by its narrative the period from A.D. 25 to 1018. Of this work, which exists in only one imperfect copy, the later portion was edited by Baethgen in 1884, and the earlier by Lamy in 1888. Another important *Chronicle* is that of Michael I., who was Jacobite patriarch from 1166 to 1199. Its range extends from the Creation to the author's own day, and it was largely used by Barhebraeus in compiling his own *Chronicle*. Till recently it was known only in an abridged Armenian version which was translated into French by V. Langlois (Venice, 1868): but the Syriac text was found in a ms. belonging to the library of the church at Edessa, and has been published by J. B. Chabot. A work rather legendary than historical is the *Book of the Bee*, by Solomon of al-Baṣrah, who lived early in the 13th century. Lastly, acknowledgment must be made of the great value of the Catalogue of Nestorian writers, by 'Abhdīshō' of Nisībis, the latest important writer in Syriac. It was edited by Assemani in the 3rd part of his *Bibliotheca orientalis*, and has been translated into English by Badger.

3. *Biography, Monastic ,History, etc.*—Besides the important work by Thomas of Margā (*q.v.*) the following deserve special mention. Sāhdōnā, who was a monk in the Nestorian monastery of Bēth 'Ābhē (the same to which Thomas of Margā belonged two centuries later) and afterwards a bishop early in the 7th century, wrote a biography of and a funeral sermon on his superior Mār Jacob who founded the monastery, and also a long treatise in two parts on the monastic life of which all that survives has been edited by P. Bedjan (Paris, 1902). Whilst accompanying the catholicus Īshō'yabh II. (628–644) on a mission to Heraclius, Sāhdōnā was converted, apparently to Catholicism (*see* H. Goussen, *Martyrius-Sahdonas Leben und Werke*, Leipzig, 1897), and thereby caused much scandal in the East. The chief events in his life are narrated by Ishō'dĕnaḥ. Another Nestorian who, a few years later, wrote ecclesiastical biographies and other theological works was Sabhrīshō' Rusṭam, who lived at Mount Īzlā and other monasteries. In the beginning of the 8th century David of Bēth Rabhan, also a Nestorian monk, wrote, besides a geographical work, "a monastic history, called *The Little Paradise*, which is frequently cited by Thomas of Margā." A more important work is *The Book of Chastity*, by Ishō'dĕnaḥ, who according to 'Abhdīshō' was bishop of Ḳaṣrā—but read Baṣrā—about the end of the 8th century. This work is a collection of lives of holy men who founded monasteries in the East, and is a valuable historical source. The work itself, or an abridgment of it, was discovered and published for the first time by J. B. Chabot (Rome, 1896). As the last under this head we may mention a late anonymous biography, that of the catholicus Yabhalāhā III. (1281–1317), which throws much light on the relations of the early Mongol kings with the heads of the church in their dominions. Among other interesting features it contains information about the Nestorian Church of China in the 13th century.

4. *Philosophy and Science.*—Special mention may be made of 'Ānānīshō' of Ḥědhaiyabh (middle of 7th century) well known as the author of a new recension of the *Paradise* of Palladius, and also the author of a volume on philosophical divisions and definitions; Romanus the physician (d. 896), who wrote a medical compilation, a commentary on the Book of Hierotheus, a collection of Pythagorean maxims and other works; Moses bar Kēphā, the voluminous writer above referred to; the famous physician Ḥonain ibn Iṣḥāḳ (d. 873), who wrote chiefly in Arabic, but deserves mention here by his services to Syriac grammar and lexicography, and still more by his translations of Greek philosoph-

ical and scientific works into Syriac and from Syriac into Arabic, becoming in a sense the founder of a school of translators; and Jacob bar Shakkō, whose work called the *Dialogues* treats of grammar, rhetoric, poetry, logic, philosophy and science.

5. *Grammar and Lexicography.*—Several of the authors in this department have already been mentioned. The more important, besides Jacob of Edessa and Barhebraeus, are 'Anānīshō' of Hēdhaiyabh, Ḥonain ibn Iṣḥāḳ, his pupil Bar 'Alī, Bar Sarōshwai (early 10th century), Bar Bahlūl (middle of 10th century), Elias of Ṭirhān (d. 1049), Elias bar Shīnāyā (above), John bar Zō'bī (beginning of 13th century) and Jacob bar Shakkō.

See W. Wright, *History of Syriac Literature* (1895); R. Duval, *La Littérature syriaque* (3rd ed. 1907); A. Baumstark, *Geschichte der syrischen Literatur* (1922). (N. M'L.)

SYRINGA, the common name applied to several cultivated ornamental shrubs of the genus *Philadelphus*, of the family Saxifragaceae (*q.v.*). The name arose from the fact that the original generic name of these shrubs was *Syringa*, which, however, properly belongs to the lilac (*q.v.*). The garden syringas, better known as mock orange, are all species of *Philadelphus*. They possess conspicuous, usually strongly scented flowers and in a wild state are natives of the north temperate zone. There are about 40 species. The common garden syringa (*P. coronarius*) is Eurasian, but is found in many horticultural varieties. Noteworthy North American species are the scentless syringa (*P. inodorus*), the large-leaved syringa (*P. grandiflorus*) of the southeastern U.S., and the western syringa (*P. lewisi*), state flower of Idaho, found from Montana to British Columbia and Oregon.

SYRINGE, a hydraulic instrument, based on the principle of the pump, for the drawing up and ejecting of liquids. The ordinary form is that of a glass or metal tube ending in a pointed nozzle and fitted with an airtight piston rod and handle. The nozzle is inserted in the liquid, which enters the cylinder by atmospheric pressure when the piston rod is drawn up. On pushing back the piston the fluid is ejected in a jet through the nozzle. In sizes varying from the needle-pointed hypodermic syringe to the abdominal syringe, it is a common surgical implement used for the injection of fluids into the body or for the washing of wounds and cavities. A large syringe of metal with a flat perforated nozzle is used as a garden implement for watering plants.

SYRINX, the Greek name for the musical instrument more commonly known as the panpipes (*see* PANPIPE). Syrinx is also a term used in the fields of medicine and anatomy, meaning: (1) a tubelike structure; (2) a fistula; and (3) a kind of secondary larynx found in birds.

SYRYENIANS (also Sirianian, Syrjenian, Zyrenian, Zirianian, Zyrian and Zirian), a tribe of the Permian division of the eastern Finns. Their headquarters are at Ust-Ishma, at the junction of the Ishma and Pechora. Formerly they spread farther to the west. They are of moderate stature, blond and grey-eyed, energetic and inclined to trade. They were converted to Christianity about 1350 and their language was reduced to writing. They call themselves Komi and are not sharply distinguished from the tribes known as Permian, the languages being mutually intelligible. The archaeological remains in the governments of Perm and Vyatka called Chudish by Russians are probably Syryenian.

SYZRAN, a town of the Russian Soviet Federated Socialist Republic, U.S.S.R., in the Kuibyshev *oblast*, in latitude 53° 10′ N., longitude 48° 33′ E., on the right bank of the Volga. Pop. (1959) 148,866. It is a railway junction on the Moscow-Orenburg and Kazan-Volgograd lines.

The town, founded in 1683, was originally a fort to protect settlers from Tatar raids, but developed into a manufacturing centre, with river and rail trade in exported grain and imported timber and manufactured goods. Industries include the manufacture of building materials and locomotives and petroleum refinery.

SYZYGY, in astronomy, either of the points at which the moon is most nearly in a line with the earth and sun. The moon passes its syzygies, or is in a syzygy, at new and full moon.

SZCZECIN (German STETTIN), the chief town of western Pomorze (Pomerania) Szczecin *wojewodztwo* (province), Pol., and the main Polish seaport, lies on the left bank of the Oder (Odra) 17 mi. above its entrance into the Gulf of Szczecin and about 40 mi. from the Baltic sea. Pop. (1939 census) 268,915; (1950 census) 178,207; (1960 census) 268,900. Area 110 sq.mi.

Outside the old walled city, which was built high above the river level, stands the church of SS. Peter and Paul. Founded in 1124, it is the oldest Christian church of western Pomerania; it was restored in the 15th century and again in 1816–17. Within the city walls, dismantled in 1874, the Pomeranian dukes of the 13th century built a castle, which was often rebuilt and enlarged. The old city contained also the huge Gothic churches of St. John (founded 1240) and St. James (14th century), both destroyed in World War II. The gates of the fortifications built by Frederick the Great still stand.

The modern city of Szczecin was built to the north and west of the old city in the second half of the 19th and the beginning of the 20th century. Well-planned, with wide avenues and many parks and open spaces, its central point is the Grunwald square from which radiate eight streets. Since 1945 a medical school, a college of engineering and a school of agriculture have been established. The town has three theatres and issues two local daily newspapers and a literary weekly paper. The local broadcasting station covers the whole coastal area of Poland and the Baltic countries.

About 80% of the old city and 50% of the new were destroyed by two massive British air raids in Aug. 1944 and by the Russian heavy artillery fire during the last stages of World War II. By 1957 reconstruction of the city had made considerable progress.

Szczecin was first mentioned in a document known as *Dagome index*, dating from the first half of the 10th century, by which Prince Mieczyslaw or Mieszko I, the founder of the Piast dynasty of Poland, put the town of Schinesghe under the Holy See's protection. The name of the town comes from *szczecina* (bristle) and it was known to the Danes as Børstaborg (brush castle). In 1124 Christianity was introduced by Otto, bishop of Bamberg, whose mission was sponsored by Boleslaw III Wrymouth, king of Poland, and the Slavonic population, consisting largely of fishermen and craftsmen, was baptized. In 1243 Szczecin received municipal autonomy from Duke Barnim I and it remained the capital of the dukedom of Pomerania or Pomorze (*q.v.*) until 1637. Already a leading centre of trade, it joined the Hanseatic league (*q.v.*) in 1360. From 1648 to 1720, when it was ceded to Prussia, it belonged to Sweden and it remained Prussian until the end of World War II. Catherine the Great, empress of Russia, was born in Szczecin. The Potsdam agreement of Aug. 2, 1945, restored the town to Poland and all Szczecin's German inhabitants who had not already fled were transferred to Germany. By 1957 the population figure was almost as high as in 1939 but the inhabitants were exclusively Polish.

Szczecin exports coal and imports iron ore from Scandinavia. It also handles transit traffic between the central European countries and the far east. After 1945 its docks were enlarged and installations were repaired. Goods loaded and unloaded during 1953–56 amounted to 6,323,000 metric tons annually. The port is linked with its hinterland by the navigable Oder and with overseas countries by nine regular shipping lines. Eight railway lines join it to the rest of Poland and from the airport at Zdroje, 2 mi. from the town, there are services to Warsaw and Poznan. Szczecin has one of the two biggest Polish shipyards, capable of building ships up to 10,000 gross tons. It is also an industrial centre; its largest enterprises are a paper and cellulose plant, a phosphatic fertilizer plant, a synthetic yarn mill, ironworks, a cement factory and a motor-vehicle repair shop. These were largely destroyed in World War II but were later entirely rebuilt.

SZÉCHENYI, ISTVAN, COUNT (1791–1860), Hungarian statesman, born at Vienna on Sept. 21, 1791, who was called "the greatest of the Magyars" by his political antagonist F. Kossuth, was the son of Ferencz Széchenyi and the countess Juliana Festetics. Entering the army at the age of 17, he fought with distinction at the battle of Raab (June 14, 1809), and on July 16 brought about the subsequent junction of the two Austrian armies by conveying a message across the Danube to Gen. J. G. Chasteler at the risk of his

life. Equally memorable was his famous ride through the enemy's lines on the night of Oct. 16–17, 1813, to convey to Blücher and Bernadotte orders for the impending battle of Leipzig. In May 1815 he was transferred to Italy, and at the battle of Tolentino scattered Murat's bodyguard by a dashing cavalry charge. From Sept. 1815 to 1821 he traveled widely, studying the institutions of the countries through which he passed. A second tour with his friend, Baron Miklos Wesselényi, taught him much about trade and industry.

In 1825, when he went to France to attend the coronation of Charles X, the canal du Midi attracted his attention and suggested to him the idea of regulating the Danube and Theiss rivers. At the diet of 1825, when the motion for founding a Hungarian academy was made by Pál Nagy, who bitterly reproached the Magyar nobles for so long neglecting their mother tongue, Széchenyi set the example by offering to contribute a whole year's income (60,000 florins) toward it. The formation (June 1833) of the Danube Navigation company, which eventually opened up the Danube from Buda to the Black sea, was the fruit of Széchenyi's initiative and personal study. Széchenyi was also the first to start steamboats on the Theiss, the Danube and the lake of Balaton.

All this time Széchenyi had been following, with some anxiety, the political course of Kossuth, whose extravagances he feared would plunge Hungary back into the chaos out of which he had helped to raise it. The majority, indeed, sided with Kossuth, but neither this fact nor the gradual loss of his popularity restrained Széchenyi, both in the diet and at county meetings, from fulminating conscientiously against the extreme demands of Kossuth. His views at this period are expounded in the pamphlet *Politikai programm töredékek* ("Fragments of a Political Program"). He held the portfolio of ways and communications in the first responsible Magyar administration (March 23, 1848) under L. Bátthyány, but he became mentally ill and on Sept. 5 he was taken to an asylum. He took his own life on April 8, 1860.

See Antál Zichy, *Biographical Sketch of Count Stephen Széchenyi*, 2 vol. (1896–97).

SZECHWAN (SSU-CH'UAN SHENG), a province of southwest China, almost 220,000 sq.mi. in area following the reaccession of Sikang (*q.v.*), 1955. Pop. (1953) 65,685,063 (including Sikang); (1957 est.) 72,160,000. It contains four autonomous areas formed since 1952 inhabited predominantly by non-Han peoples (under 2% of total provincial population) living in the mountainous west and southwest: Ahpa (A-pa), Kantse and Muli—all mainly Tibetan; and the Liangshan Yi area. Szechwan was once almost a separate country by size and population, as well as being self-sufficient in resources.

Geography.—Topographically it is distinctive with lofty mountains everywhere and tremendous rivers of unmeasured power potential. From cloud-ringed O-mei Shan, 9,900 ft. (famed for temples, monkeys and pines), southwest of Ch'eng-tu, to the infinite complexity of irrigated garden-patch farms, and the inspiring 1,000–2,000 ft. gorges of the Yangtze (*q.v.*), the marks of man's adjustment and transformation of the landscape are everywhere. The heart of the province is the Szechwan or Red basin that occupies a region that continued as a sea gulf well into the later Paleozoic period, and changed to a fresh-water lake during the Mesozoic with deposition of red sandstones and limestones that were later wrinkled into a northeast-southwest ridge and valley system. On the west are the young Great Snow mountains (Tahsüeh Shan) and the eastern plateau of Tibet, 13,000 ft. above sea level; to the north, the Tsinling Shan (*q.v.*) at 10,000 ft. runs into the Ta-pa Shan and Wu Shan on the east, while the south is marked by the limestone plateau of Kweichow. The largest flat area is the Ch'eng-tu plain in the northwest of the basin. Szechwan means "four streams"; they are usually regarded as the Min, T'o, Chia-ling and the Ch'ien or Wu; sometimes either the Yangtze or Fou Chiang is given instead of the Ch'ien. Most of the major streams flow south, cutting steep gorges through former Sikang, or widening their valley floors in the soft sediments of the Red basin to pour eventually into the Yangtze before it slices its precipitous gorge, 150 mi. due east, through the Wu Shan below Wan-hsien. Within the basin most of the rivers are navigable and provide the most common means of transportation. Inside the mountain ring, which provides a barrier against polar winds, a mild climate permits the growth of almost every crop and tree found in China. Precipitation averages 40 in., and the growing season is 11 months; snow and freezing are rare although the foggy winters are penetrating. Because of the high humidity and constant cloud cover, the Chinese say that in Szechwan the dogs bark when they see the sun.

Agriculture.—Given favourable conditions for agriculture the large population has converted lowlands and terraced hillsides into intensive gardens everywhere. Rice, sweet potatoes, sugar cane, silk, tea, citrus, tobacco, cotton and tung oil are the primary products, with wheat, corn, soy beans, white potatoes and barley as secondary. Bamboo and palms on the lowlands are matched by conifers and alpine meadows on the high mountains. Szechwan is China's largest rice producer with surpluses for transport to deficit areas, along with outshipments of sugar, citrus, tung oil, spices and medicinal products. Liang-shan writing paper made from bamboo is prized by Chinese artists. The world's best natural bristle is plucked from the backs of Szechwan hogs; goats are also reared. Within high, secluded bamboo glades in the west live the rare giant panda bears.

Industry.—Minerals of industrial importance are increasingly exploited. Salt has long been pumped from natural brine wells, from 300 to more than 1,000 ft. deep, at Tze Kung, while bituminous coal outcrops are numerous around Chungking. Iron ores are scattered; the largest deposit, estimated at 500,000,000 tons of about 40% iron content, is in the southeast of former Sikang province. Petroleum is reported extracted and refined on the middle Chia-ling river, less than 90 mi. N. of Chungking (*q.v.*), while in the salt well area natural gas is also being converted into petroleum. Szechwan's first major hydroelectric station (48,000 kw.) was built northeast of Chungking on the Lungch'i. From the mountains in the west, small amounts of gold, silver, copper, lead, antimony and asbestos are produced. The pace of industrialization continues to increase. Chungking, the major industrial centre of southwest China, has an automatic thermoelectric power plant, iron and steel plants (open hearth and electric), textile mills, chemical works and lighter industries. Electric trolley buses run in the widened downtown streets, while cable cars have replaced many of the long flights of stone steps down to the rivers. In 1952 Szechwan's first railway, 313 mi., between Chungking and Ch'eng-tu, the provincial capital, was opened, followed in 1958 by the Pao-chi to Ch'eng-tu line, 400 mi. across the Tsinling Shan to the north. Two more lines are growing south, one from Chungking to Kuei-yang in Kweichow (190 mi.), by a bridge across the Yangtze; the other from Nei-chiang, the sugar centre, to K'un-ming in Yunnan (420 mi.). Ch'eng-tu is the terminus of the motor roads to the west. That change will continue is obvious, for there remains the challenge of damming the lower end of the great Yangtze gorges, a project first drafted during World War II and taken up again in China in the late 1950s; this would be one of the world's largest multipurpose river control projects, with 10,000,000 kw. power available for a 300-mi. area.

History.—In the past the keynote of Szechwan was isolation. Non-Han peoples related to the Thai stocks had their centres of the Shu and Pa states at Ch'eng-tu and Chungking respectively at least as early as the Chinese settlement in the Yellow river valley. They were conquered by the Ch'in from the north in 316 B.C., augmented by a large number of transported Chinese settlers who enlarged Ch'eng-tu's great irrigation system and built the walled city. A possible remnant of the pre-Chinese exists southwest of the Min Chiang in the Liangshan Yi autonomous area formed in 1952. During the Three Kingdoms period (A.D. 221–265), Ch'eng-tu formed part of the base of Chu-ko Liang, one of China's shrewdest and most admired historical strategists. At the end of the Ming dynasty widespread massacres left vacant land that was occupied in the 18th century by whole outside communities—most notably a large contingent from Kwangtung whose descendants around Ch'eng-tu still speak Cantonese. Since the main routes into Szechwan were over the Tsinling Shan, with the shift of Chinese power east and then south the province was some-

what forgotten except as a rice granary and control base against the non-Hans to the west. During the warlord days of the republic, the area was practically impregnable. After the start of the Chinese–Japanese war in 1937, industrial enterprises and millions of refugees from coastal provinces were evacuated to Szechwan which resulted in rapid economic development of the area. Chungking, former treaty port and the wartime capital of China, made Szechwan the political and economic centre and became the site of important military bases and headquarters installations for Chinese and allied forces.

Although the Japanese bombing of Szechwan cities, especially the capital, was severe, the province was not entered by the invaders. However, in spite of other large cities like Ch'eng-tu, Luchow, Wan-hsien and I-pin (*qq.v.*), most of the population remains basically rural. (TE. H.)

SZEGED, a city in, but independent of, the county of Csongrád, Hung. It lies just below the confluence of the Maros and Tisza rivers. Pop. (1949) 83,207; (1960) 99,061 (mun.). It is modern, the old town having been almost destroyed by a Tisza flood in 1879. In early times it was important because it lay on the salt and timber route from Transylvania to the Adriatic. A large cotton mill was built there in 1947–49. The city also has a shoe factory and food-processing plants. It is the seat of a university.

SZÉKESFEHÉRVÁR (German STUHLWEISSENBURG), a town in Hungary, capital of the county of Fejér, lies in a marshy valley, 40 mi. S.W. of Budapest. The town was the coronation and burial place of the Hungarian kings from the 10th to the 16th century. The coronation church was built by St. Stephen, the first king of Hungary. From 1543 to 1688 it was under Turkish occupation. In 1601 it was taken by the Austrians and the church with its tombs was destroyed. In the 1950s it became a centre of the aluminum industry. Pop. (1960) 55,934 (mun.).

SZEKLERS (Magyar *Székely*), a people inhabiting the upper valleys of the Mures and Olt rivers in what was eastern Transylvania and is now Rumania. It has been estimated that they number about 450,000, but they are no longer distinguishable from the Magyars, with whom they are closely akin. Their origin has been much debated. According to their own tradition, repeated in Procopius's *De bello Gothico*, they were descended from Attila's Huns, while others have seen in them Black Ugrians. It is, however, now generally accepted that they are true Magyars, transplanted there probably by St. Ladislaus to guard the frontier, their name meaning simply "frontier guards."

SZÉLL, KOLOMAN (1845–1915), Hungarian statesman, was born on June 8, 1845. He studied at Budapest and Vienna, and in 1867 became deputy for the district of St. Gotthard. In 1875 he was finance minister in I. Tisza's cabinet, and began the task of restoring the credit of Hungary.

In 1878 he concluded with Austria the first economic *Ausgleich*. At that time the single Austrian bank was changed, in conformity with this arrangement, into the dualistic Austro-Hungarian bank, and Széll consolidated the Hungarian *rentes*, and nearly succeeded in balancing the state finances. As he feared that this balance would again be upset by the occupation of Bosnia and Herzegovina, he resigned from the cabinet, incurring thereby the displeasure of the crown. At the beginning of the 1880s Széll founded the Hungarian Mortgage Credit bank, of which he was governor until the end of his life. He opened entirely new sources of credit for Hungarian agriculture. He declined repeated offers of the portfolio of finance. Széll became prime minister after the fall of D. Bánffy in Feb. 1899. On the basis of the so-called Széll formula the new *Ausgleich* with Austria until the year 1907 was concluded after long negotiations. He was forced to resign on June 16, 1903. Széll was one of the Liberal seceders in 1904. Under the coalition cabinet of A. Wekerle, he was chosen president of the Constitutional party. He tried in vain to bridge the opposition between Tisza and J. Andrássy. He died on Aug. 16, 1915.

SZENT-GYÖRGYI, ALBERT (1893–), Hungarian-U.S. biochemist, who was awarded the 1937 Nobel prize for medicine and physiology "for his discoveries in connection with the biological combustion processes, with especial reference to vitamin C and the catalysis of fumaric acid." He was born in Budapest, Sept. 16, 1893. His medical education at Budapest was interrupted by World War I, but he used an interval of leave after being wounded to complete his studies and graduate M.D. (1917). After the war he held posts at Pozsony (later Bratislava), Prague, Berlin, Hamburg, Leyden and Groningen. In 1927 he transferred his laboratory to Cambridge, Eng., and subsequently spent a year in the United States. He returned to Hungary in 1932 and held the chairs of medical chemistry at Szeged and at Budapest. In 1947 he emigrated to the United States and became director of the Institute for Muscle Research at the Marine Biological laboratory at Woods Hole, Mass. Szent-Györgyi's greatest achievement was the isolation from the adrenal glands and from various plant juices of hexuronic acid (ascorbic acid) and the provision of definite proof that this substance is identical with vitamin C. He was also the first to demonstrate the presence of flavin (riboflavin or vitamin B_2) in animal tissues. With S. Ruznyak he discovered vitamin P, which regulates vascular permeability. (W. J. BP.)

SZOLD, HENRIETTA (1860–1945) founder of what became through her leadership the world's largest Zionist group, Hadassah, the Women's Zionist Organization of America, was born in Baltimore, Md., Dec. 21, 1860. She pioneered in Americanization work after 1882, originating (1891) the night school for immigrant workers in Baltimore. A founder of the Jewish Publication Society of America (1888), she served until 1916 as the society's editor general, translator of Jewish classics and writer. In 1912, with 12 members, Miss Szold founded Hadassah. As its president she organized in 1916 a medical unit for Palestine comprising staff and equipment for hospitals, nurses' school, clinics and epidemiological and teaching services. The first woman elected to the World Zionist executive and member of the Palestine Jewish National council, she held their portfolios of health, education and social welfare. She established Lemaan Hayeled (named after her death the Szold foundation) for child welfare and research in juvenile problems. In 1933 she became director of Youth Aliyah, a world-wide movement to rescue and rehabilitate in Israel young victims of Nazi and other persecution. She worked also for Arab-Jewish *rapprochement* through common social and political planning. Miss Szold died in Jerusalem Feb. 13, 1945. She was recognized as the outstanding Jewish woman of her time, a pioneer in international social service, education and Zionist thinking.

See Marvin Lowenthal, *Henrietta Szold, Life and Letters* (1942); Rose Zeitlin, *Henrietta Szold* (1952). (T. DE S. P.)

SZOMBATHELY, a town in western Hungary, that occupies the site of the Roman capital of Pannonia, Sabaria or Savaria. The town lies in the centre of a rich wine-producing downland and is an important agricultural centre with steam flour and saw mills and factories producing agricultural machinery and textiles in addition to foundries and a state railway workshop. It has been the see of a Roman Catholic bishop since 1777 and possesses a beautiful cathedral and several other ecclesiastical buildings. Pop. (1960) 54,465 (mun.).

SZYMANOWSKI, KAROL MACIEJ (1882–1937), the principal Polish composer of orchestral music and the leading figure in the Polish musical revival. Born on Oct. 6, 1882 (new style) at Timoshovka, near Elisavetgrad in the Ukraine, he studied with his father and Gustav Heuhas and in 1901 with Z. Noskowski in Warsaw. His early piano works include preludes, studies and the variations, opus 3. Though influenced by Scriabin and Richard Strauss, his style developed between 1909 and 1913 in his second symphony, second piano sonata and the opera *Hagith* (Warsaw, 1922). During World War I he wrote his third symphony, showing oriental affinities, *Métopes* for piano, the *Mythes* for violin, including *The Fountain of Arethusa*, and the first violin concerto. Szymanowski's later works were remarkable for their lyrical inspiration and ornate craftsmanship. The best of his songs were written from 1915 onward and include the cycle *Slopiewnie*. His style reached maturity in the opera *Król Roger*, containing the well-known "Song of Roxana" (Warsaw, 1926). Folk-song elements were used in his ballet *Harnasie*, and in his *Stabat Mater* and *Litania* he revived an archaic style. In 1926 he became director of the Warsaw conservatory. His last compositions include the *Symphonie Concertante* and the second violin concerto. He died at Lausanne, March 29, 1937.

See Stefania Lobaczewska, *Karol Szymanowski* (1950).

THIS letter corresponds to Semitic *tau* (meaning "mark"), the form of which on the Moabite stone was X. In all Greek alphabets, as well as in the Lydian and the Latin, the form was T. Etruscan had a form ⊤, from which probably were derived the Umbrian form ⊤ and the Faliscan ⊤ and ⅄.

Latin cursive gives a form that leans to the right ⊢. Carolingian ꞇ is based upon uncial ꞇ. Generally speaking, in medieval manuscripts the letter did not rise above the line and it is sometimes difficult to distinguish from a minuscule *c*. In modern handwriting and printing it is the custom to extend the vertical stroke above the horizontal.

THE DEVELOPMENT OF THE LETTER "T" FROM THE PHOENICIAN THROUGH THE CLASSICAL, DOWN TO THE PRESENT FORM

The sound represented by the letter throughout its history has been the unvoiced dental stop. In English this has become more alveolar than dental, that is to say, it is pronounced by the tongue pressing upon the gums rather than the teeth. English unvoiced stops are probably also to be distinguished from the corresponding sounds in ancient Greek by the addition of a slight puff of breath following the sound, thus bringing the sound near to being an aspirate. Greek would perhaps have transliterated the English unvoiced stops by the letters θ, ϕ and χ rather than τ, π and κ. This tendency toward aspiration is carried to much farther lengths in the Irish dialects of English.

For an account of the Germanic consonant shifts involving the letter T, according to Grimm's law, *see* GERMANIC LANGUAGES.

(B. F. C. A.; J. W. P.)

TAAFFE, EDUARD FRANZ JOSEPH VON, COUNT [11th Viscount Taaffe and baron of Ballymote, in the peerage of Ireland] (1833–1895), Austrian statesman, was born at Vienna, Feb. 24, 1833, second son of Count Ludwig Patrick Taaffe (1791–1855), who was minister of justice in 1848 and president of the court of appeal. As a child Taaffe was one of the chosen companions of the young archduke, afterward emperor, Francis Joseph. In 1852 he entered the public service; in 1867 he was *Statthalter* of upper Austria, and minister of the interior in Beust's administration. In June he became vice-president of the ministry, and at the end of the year he entered the first ministry of the newly organized Austrian portion of the monarchy. For the next three years he took a very important part in the confused political changes, representing essentially the wishes of the emperor. From Sept. 1868 to Jan. 1870 he was president of the cabinet. In 1870 Taaffe, with the other members of the cabinet who advocated concessions to federalism, resigned. He returned to office in April, resigned once more, and became *Statthalter* of Tirol.

On the breakdown of the Liberal government in 1879 he was again called to office, becoming minister-president in July, and held office until July 1893, when he was defeated on a proposal for the extension of the franchise and resigned, dying at Ellerschau, Bohemia, on Nov. 29, 1895. For the history of Taaffe's administration, *see* AUSTRIA, EMPIRE OF. Essentially an opportunist, he maintained office for many years by an unprecedented employment of the principle *divide et impera*. Usually resting on the Slavs and clericals, he was accused by the German Liberals of ruining Austria; but he united a deep devotion to the emperor with a singular gift for managing men and at least prolonged the life of an impossible system.

By the death of his elder brother Charles (1823–1873), a colonel in the Austrian army, Taaffe succeeded to the Austrian and Irish titles. He married in 1862 Countess Irma Tsaky, by whom he left four daughters and one son, Henry.

See Wurzbach, *Biographisches Lexicon Oesterreichs, Memoirs of the Family of Taaffe* (1856), privately printed; and Taaffe's *Political Correspondence* issued after his death.

TAAL, a municipality (with administrative centre and 48 *barrios* or districts), of the province of Batangas, Luzon, Philippines, on the Pansipit river. It is about 50 mi. S. of Manila and near to Lake Taal. Pop. (1959 est.) 31,905.

On an island in the lake of Taal is a volcano which has erupted many times, notably in Jan. 1911. The consequently fertile surrounding lands produce palay (rice), maize (corn), sugar and other crops. The manufacture of baskets, mats, harness, shoes, slippers, embroidery and bolos is extensive, while horse and cattle breeding and fishing are also carried on. Tagalog is the vernacular. (C. S. L.)

TABACO, a municipality and port of entry of the province of Albay, Luzon, Philippines, on Tabaco bay, a protected harbour about 20 mi. N. of Albay (Legaspi), the provincial capital. Pop. (1959 est.) 40,683.

The chief agricultural produce is abacá (Manila hemp). Cloth, baskets and mats are woven by the women. Tabaco is a port of entry in Albay province and has considerable trade. Bikol is the vernacular. (C. S. L.)

TABARI, AL- (ABU JA'FAR MOHAMMED IBN JARIR AL-TABARI) (*c.* 838–923), Arab historian and theologian, was the author of a history of the world generally known as the *Annals*. Born at Amol in Tabaristan he studied in Baghdad, Syria and Egypt. Most of the rest of his life he spent in Baghdad, first as tutor to the vizier's son, then as a teacher of law and Tradition.

Originally a follower of the Shafi'ite school of law he later established a school of his own; its influence was, however, short-lived. The *Annals* (*Tarikh al-Rusul wa-al Mulk*, "History of the Prophets and Kings") are a general history from the Creation to A.D. 915 and are famous for their detail and, in the later parts, their accuracy (*see* ARABIC LITERATURE: *History and Biography*).

His second great work, a commentary on the Koran (*Jami' al-Bayan* or *Tafsir*) is marked by the same fullness of detail as the *Annals*.

Bibliography.—The *Annals* were ed. by M. J. de Goeje, 13 vol. (1879–1901). The commentary on the Koran was published in 10 vol. (1905–12), ed. by M. M. Shakir and A. M. Shakir, 3 vol. (1954–). *See* also D. S. Margoliouth, *Lectures on Arabic Historians* (1930).

TABASCO, a gulf coast state of southeast Mexico. Area 9,783 sq.mi. Pop. (1950) 362,716. The surface is generally low and flat, largely covered with lagoons, watercourses and swamps. In the south and southeast there is a higher area. Tabasco, a region of very heavy rainfall, is covered by dense forests which provide valuable fine woods and dyewoods. It is traversed by two large rivers, the Grijalva and Usumacinta. The Grijalva, also called Tabasco, is navigable for 62 mi. The Usumacinta forms the boundary between Guatemala and Chiapas until the frontier of Tabasco is reached, then it flows into the Grijalva—the two rivers having a common outlet. The Usumacinta, including its headstreams, is about 500 mi. long; it is navigable for about 310 mi. but only about 180 mi. by large steamers. There are few good roads, and the rivers are the principal means of transportation in the state. There are also air and rail lines. The state capital is Villahermosa (pop. [1950] 33,587), on the Grijalva river. The next most important town is Frontera (pop. [1950] 8,449), a port 3 mi. within the mouth of the Grijalva.

Juan de Grijalva explored the area in 1518, and in 1519 Cortés first clashed with the Indians, from whom he acquired his faithful Doña Marina. Francisco de Montejo partially subdued them after constant uprisings in the 1530s and 1540s. Tabasco, an Indian name meaning "damp earth," became a state in 1824. The potential oil wealth of the area began to be exploited in the 1950s. Cattle, copra, bananas, cocoa, coffee, rice, sugar cane, rubber, vanilla, tropical fruits and corn are the main agricultural products.

(J. A. Cw.)

TABERNACLE, the name given in the English Bible to the portable sanctuary, erected by Moses in the wilderness as the place of worship of the Hebrew tribes (Exod. xxv. *sqq.*). It stood within a rectangular court, measuring 100 cubits by 50, say 150 feet by 75, which formed the centre of the camp in the wilderness. Of the two equal squares into which the court may be divided, the more easterly was that in which the worshippers assembled. In the centre of this square stood the altar of burnt-offering, a hollow chest of acacia wood overlaid with bronze. In the western square stood the tabernacle itself. The essential part of the structure was that termed in the original the *mishkān, i.e.,* dwelling. It was formed of ten curtains, in two sets of five, of the finest linen with inwoven coloured figures of cherubim spread over a series of open frames of acacia wood overlaid with gold, each 10 cubits in height by 1½ in breadth. These frames, 48 in all, were so arranged as to form the southern, western and northern sides of a rectangular structure, 30 cubits in length and 10 in breadth and height, whose eastern end, forming the entrance, was closed by a special portière suspended from five pillars. The dwelling was divided into two parts by a second hanging, the "veil," 10 cubits from the western end. These two parts were termed respectively the holy place, and the most holy place or "holy of holies." Within the latter stood the ark of God, in which were deposited the two stone tables of the decalogue or "testimony." On the ark lay a solid slab of the finest gold, the propitiatory or mercy-seat, from which rose the figures of two golden cherubim, forming the innermost shrine of the wilderness sanctuary, the earthly throne of the God of heaven.

The furniture of the holy place consisted of the table of shewbread, the altar of incense—both, like the ark, of acacia wood overlaid with gold—and the golden "candlestick," or seven-branched lamp-stand. As a protection the delicate and artistic curtains of the dwelling were covered by two similar sets of goats'-hair curtains; these, in their turn, were protected by a double covering, the one of rams' skins dyed red, the other made of the skins of a Red Sea mammal, probably the dugong (Exod. xxvi. 14).

The aim of the "priestly" writers, to whom we owe this conception of the tabernacle, was to provide a sanctuary and a ritual worthy of the higher conceptions of the Deity, which had grown up as the fruit of the discipline of the exile. The thought of the almost unapproachable holiness of the Deity underlies not only the gradation of the parts of the tabernacle—court, holy place and holy of holies, each marked by an ascending degree of sanctity—but also the careful gradation of the materials employed in its construction. The whole is to be regarded as the expression of a religious ideal. Building on the traditions of the simple Mosaic "tent of meeting," the priestly idealists followed the example of Ezekiel, and elaborated a sanctuary to serve as the model for the worship of the theocratic community of the future. "Let them make me a sanctuary, that I may dwell among them" (Exod. xxv. 8).

Bibliography.—*See* "Tabernacle" by Kennedy in Hastings' *D.B.,* with which may be compared the corresponding articles in the *Ency. Bib.* by Benzinger, and in the *Jewish Encycl.* by König; also the commentaries on Exodus. (A. R. S. K.)

In architecture, the term loosely expresses a niche for a statue, with a canopy (*q.v.*) over it, especially in the mediaeval styles. When niches are arranged in vertical rows, with the canopy over one statue acting as the pedestal for the one above, the whole composition is often termed tabernacle work. The same term is also used for any richly decorated tabernacle or canopy-like forms, whether true tabernacles or not.

TABERNACLES, FEAST OF. A famous Jewish festival which commences on 15 Tishri (five days after the Day of Atonement), and lasts seven days. Of these the first two (Tishri 15 and 16) are full festival days, the last five (Tishri 17–21) half-holidays. The "eighth day" Festival (Shemini Aisereth), which like other festival days is doubled (Tishri 22 and 23; the second day in this case is called *Simchath Torah*), closes the celebration. The whole nine days bear one descriptive designation, "season of our rejoicing." The festival is one of venerable antiquity. Its observance is commanded in the Mosaic Law (Lev. xxiii. 34), and its purpose is there explained as to commemorate the way in which the Israelites dwelt in booths (*sukkoth*) in the wilderness.

Every Jew who owns a court or garden is required to erect a booth or something more or less equivalent, and to dwell in it—or at least have meals in it—while the feast lasts. In order that the character of the original booth may as far as possible be retained, the modern counterpart is very lightly constructed. It "must not be covered with fixed boards and beams or with canvas, but with detached branches of trees, plants, flowers and leaves, in such a manner that the covering is not quite impenetrable to wind and rain or starlight" (Friedlander). The booths are required to be made during the days that intervene between the Day of Atonement and the Feast itself; they are adorned with garlands, flowers, and the like; often the text "Ye shall dwell in booths seven days" (Lev. xxiii. 42), is displayed in a prominent place within the booth. On the eve of the Feast the members of the household attend Synagogue, and on returning assemble in their booth and partake of a meal. On this evening (the first of the Feast) the meal (as in the case of the weekly Sabbath on Friday evening) is preceded by Qiddush or the solemn sanctification, first over a cup of wine which is then handed round, all drinking of it, and then over two wheaten loaves, specially baked and placed on the table covered with a cloth; these the head of the family then proceeds to cut into pieces, which are distributed to and eaten by all present. A special blessing—which is repeated before every meal during the seven days—follows ("Blessed art Thou, O Lord . . . Who hast commanded us to dwell in a booth"). At the conclusion of the meal, and on leaving the booth the following prayer is said by the head of the household:

> May it please Thee, O Lord my God, and God of my fathers, that in like manner as I have this time obeyed Thy command and have been sitting in the booth, so in the coming year I may be counted worthy to sit in the booth of Leviathan.

It should be observed that the Leviathan plays a prominent part in haggadic legend, especially in connection with the Messianic time. The monster is to be killed and the flesh is to furnish food for the righteous (at the Messianic banquet). From the

hide tents will be made by God for the pious of the first rank. This last feature will explain the allusion in the text of the prayer.

On the occasion of the ceremony, the Synagogue is decorated with plants and fruits and certain ceremonies are carried out, viz., palm-branch processions culminating on the seventh day at the *Musaf* or additional service. (G. H. B.)

TABES DORSALIS (Locomotor Ataxia) is a form of neurosyphilis characterized by chronic degeneration in the posterior columns of the spinal cord. The disease results in loss of muscular co-ordination.

The first symptom, which occurs between about 15 to 25 years after infection, usually is a lessening or the loss of the ankle and knee reflex. As the disease progresses, the patient gradually loses his ability to walk and stand normally. Treatment is the same as for other forms of late syphilis. *See* also Venereal Diseases: *Syphilis: Late Symptomatic Syphilis.*

TABLE (Lat. *tabula*), in furniture, a flat, oblong slab supported upon legs or pillars. Of the many kinds of tables according to their uses, the following are outstanding as pieces of furniture and in artistic possibilities: (1) artist's table, (2) billiard table (*q.v.*), (3) breakfast table, (4) card table, (5) china table, (6) console table, (7) dining table, (8) dressing table, (9) library table, (10) side table, (11) sofa table, (12) tea table, (13) wine table, (14) work table, (15) writing table. The table was known in a small and rudimentary form to the Egyptians, who used wood for its construction; the Assyrians certainly employed metal and possibly other materials in its manufacture. Grecian tables were also often of metal, with three or four legs and of considerable variety of form; they were small and low. By Roman times the table had apparently become somewhat more common. The favourite form was the tripod, but one and four legs were also used. Already the shape varied considerably, and in addition to wood, there were tables of marble, ivory, bronze and the precious metals. The more costly examples were carved, inlaid or otherwise ornamented; cedar and the finely marked or grained woods generally were much sought after. As in Greece the tables were low; they were intended for reclining, rather than sitting; their legs were those of wild beasts, or were formed of sphinxes, termini and other figures. Some of those which remain are of extreme grace and most delicate workmanship; to them the Empire style is enormously indebted. In antiquity, tables of any kind can only have been the appanage of the rich. In the early middle ages, although there was variety of form—the circular, semicircular, oval and oblong were all in use—tables appear, save in rare instances, to have been portable and supported upon trestles fixed or folding, which were cleared out of the way at the end of a meal. The custom of serving dinner at several small tables, which is often supposed to be a very modern refinement, was certainly followed in the French châteaux, and probably also in the English castles, as early as the 13th century. For persons of high degree, fixed tables were reserved. Even at a period when domestic furniture was of a very primitive character and few modern conveniences had been evolved, costly tables were by no means unknown—some dim traditions of Rome's refinements must necessarily have filtered through the centuries. Thus Charlemagne possessed three tables of silver and one of gold—no doubt they were of wood covered with plates of the precious metals. Before the 16th century the number of tables properly so called was small; hence very few of earlier date than the middle of that century have come down to us. In the chapter house of Salisbury cathedral is a restored 13th-century example which stands practically alone. In point of age it is most nearly approached by the famous pair of trestle tables in the great hall at Penshurst.

When the table became a fixed and permanent piece of furniture the word board, which had long connoted it, fell into disuse save in an allusive sense, and its place was taken by such phrases as "joyned table" and "framed table"—that is, jointed or framed together by a joiner; sometimes people spoke of a standing or dormant table. They were most frequently oblong, some 2 ft. or 2 ft. 6 in. wide, and the guests sat with their backs to the wall, the other side of the table being left free for service. Sometimes they were used as side tables, or furnished with a cupboard beneath the board; they were supported on quadrangular legs or massive ends and feet, full of Gothic feeling, and were several inches higher than the dining table of the 20th century. Heavy stretchers or footrails were fixed close to the floor—for the avoidance, no doubt, of drafts. Oak was the usual material, but elm, cherry and other woods were sometimes used. Soon the legs became bulbous, and were gadrooned or otherwise ornamented, and the frame began to be carved. The introduction, before the 16th century closed, of the drawing table marked the rapidity with which this piece of furniture was developed. This was the forerunner of the extending dining table. Of the three leaves of which these tables were composed two were below the third; they drew out and were supported by brackets, while the slab proper dropped to the same level. Somewhat later legs became excessively bulbous; this ugly form gave place soon after the middle of the 17th century to baluster-shaped legs. Hitherto tables had, generally speaking, been large and massive—little in the nature of what is now called the occasional table seems to have been provided until some years after the Restoration. About that time small tables of varying sizes and shapes, but still of substantial weight, began to be made; many of them were flap tables, which took up little room when they were not in use. These, however, had been known at an earlier date. Charles II had not long been on the throne when the idea of the flap table was amplified in a peculiarly graceful fashion. Two flaps were provided instead of one, the result being the rather large oval table of the gate-leg variety that has remained in use ever since, in which the open gate supports the flap. Toward the end of the reign, tables began to have the graceful twisted legs joined to the flat serpentine stretchers, which produced, almost for the first time in English furniture, a sense of lightness and gaiety. The walnut tables of the end of the Stuart period were often inlaid with marquetry of great excellence. The number and variety of the tables in well-to-do households were now increasing rapidly, and the console table was imported from the continent contemporaneously with the common use of the mahogany side table.

As mahogany came into general use, about the beginning of the second quarter of the 18th century, an enormous number of card-tables were made with plain or cabriole legs and spade or claw and ball feet, often with lions' heads carved upon the knees; the top folded up to half its size when open. The Chippendale school introduced small tables with carved openwork galleries around the edges (to protect china and other small objects), and clustered legs; Gothic forms and Chinese frets were for a time fashionable. Later in this century, so prolific in new forms of furniture, tables were frequently made of rosewood and satinwood; side tables, often highly elaborate, adorned with swags and festoons and other classical motives, supported by termini or richly carved legs, were gilded and topped with marble slabs or inlaid wood. The Pembroke table, of oblong form, with two semicircular or oblong leaves, with edgings of marquetry, was a characteristic feature of late 18th-century English furniture, and still retains its popularity. During the Empire period the taper was replaced by the round leg, rosewood grew commoner, and brass mountings became the rule. *See* also Furniture Design and Interior Decoration, History of.

TABLE MOUNTAIN (Afrikaans, *Tafelberg*), a name frequently given in South Africa to flat-topped hills and mountains, which are a characteristic feature of the scenery. Occasionally such hills are called *plat; i.e.*, flat, *bergen*. Specifically Table mountain is the mountain which rises from the shores of Table bay, Cape Town lying at its seaward base and on its lower slopes. The mountain forms the northern end of a range of hills which terminates southward in the Cape of Good Hope. It is formed of gently inclined sandstones and quartzites of the Table Mountain Sandstone series, resting unconformably on granites, which are intruded into shales of the Malmesbury series. The sandstones descend toward sea level on the shores of False bay, but are too high to be accessible as building stone for Cape Town. The northern face of the mountain, overlooking Table bay, extends like a great wall some two miles in length, and rises precipitously to 3,567 ft. The face is scored with ravines, a particularly deep

cleft, known as Platteklip gorge, affording the shortest means of access to the summit. East and west of the mountain and a little in advance of it are lesser hills, the Devil's peak (3,567 ft.) being to the east and Lion's Head (2,178 ft.) to the west. Lion's Head ends seaward in Signal hill (1,100 ft.). The western side of Table mountain faces the Atlantic, and forms an escarpment, with a broken sky line, known as the Twelve Apostles; to the south Hout's Bay Nek connects it with the remainder of the range; on the east the mountain overlooks the Cape flats. On this side its slopes are less steep, and at its foot are Rondebosch, Newlands, Wynberg and other residential suburbs of Cape Town. The ascent of the mountain from Wynberg by Hout's Bay Nek is practicable for horses.

The southeast winds which sweep over Table mountain frequently cause the phenomenon known as "the table-cloth." The summit of the mountain is then covered by a whitish-gray cloud, which is being constantly forced down the northern face toward Cape Town, but never reaches the lower slopes. The clouds (not always caused by the southeaster) form suddenly, and the weather on the mountain is changeable. Rainfall on the summit is heavy, 72.14 in. a year being a 12-year average. This compares with an average of 54.63 in. at Bishop's Court, Newlands, at the foot of the mountain on the east, and with 25.43 in. at Cape Town (*q.v.*) at the northern foot of the mountain.

TABLES, MATHEMATICAL: *see* MATHEMATICAL TABLES.

TABLE TENNIS, an extremely fast indoor game, similar in principle to lawn tennis, was apparently derived from real or royal (indoor) tennis about 1880. It was known also under various trade-marks ("Gossima," "Ping-Pong," etc.) until 1926, when the present name was adopted by the International Table Tennis federation.

The federation, founded in Germany in Jan. 1926, called a meeting that was attended by representatives of Austria, England, Germany, Hungary, and later that season of Czechoslovakia and Sweden. Thirteen congresses were held between the years 1926–27 and 1938–39 in European cities and in Cairo, Egypt. Suspended during World War II, it held its first postwar congress in Paris in March 1947. Congresses were later held (1948–57) in Europe, India and Japan. The World Congress of 1957 was held in Stockholm, and thereafter it was held biennially beginning with the congress in Dortmund, Ger., in 1959. In that tournament Japan continued to dominate the world championships, though the men's singles championship was won by a player from Canton, China. Table tennis is a popular tournament sport in the orient and Europe but there is limited interest in tournament competition in the United States. On the other hand, it is a popular participant sport in the U.S., where tables and equipment are widely available at schools and public recreational facilities and in many private clubs and recreation rooms.

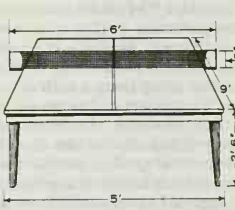

TABLE TENNIS TABLE

The Game.—Table tennis is played by striking a pale, hollow celluloid ball (4½–4¾ in. circumference, 37–39 g. weight, or 37–41 g. weight in the U.S.) with a racket over a net (6 in. high, 6 ft. long) fixed across a dark, nonreflecting table top (9 by 5 ft., 30 in. high). The blade of a modern racket is made of wood and is usually faced on both sides with stippled rubber to control the ball and to impart spin. Japan won the world championship in 1954 with a sponge-faced racket, an innovation in equipment that was banned under rules adopted by the I.T.T.F. in 1959.

The server's racket hits the ball behind his end of the table so that it bounces first on his side of the table, then over the net on his opponent's side. The ball is then struck to and fro directly over the net, after bouncing (volleying is illegal) until a point is scored by failure to make a good return. Service, after every 5 points, alternates and winner is the player who first scores 21 points; but at score 20-all service alternates after each point, and the winner must score two consecutive points. In doubles, the ball must first touch the server's right half court and after passing over the net the receiver's right court; once in play, it may be placed anywhere on the table, as in singles, except that partners must alternate in returning the ball. One U.S. close law prevents strictly defensive play; another prohibits server's imparting spin to the ball except by means of his racket.

The orthodox grip is assumed by "shaking hands" with the racket, as in lawn tennis, except that the table tennis racket or bat is not held at the end of the handle. The forefinger rests along the blade on the rear (backhand) side of the table tennis racket and the thumb on the forehand side. Slight variations from this grip are common, though "penholder" and other unorthodox grips are seldom used in tournament competition.

The basic shots are the push or half-volley, usually executed by meeting the ball with the racket in a near vertical position as the ball rises from the table; the forehand and backhand drives (characterized by topspin); and the forehand and backhand chops (which impart underspin). There are many variations.

In the United States, the U.S. Table Tennis association interprets the rules of International Table Tennis federation and publishes U.S.T.T.A. closed laws. In the early 1960s there were about 80 comparable national organizations throughout the world.

(P. W. R.)

TABLINUM, in architecture, one of the most important rooms of a Roman house, usually of large size, opening off the atrium (*q.v.*), in the centre of the side opposite the entrance. At its rear there was frequently a large window looking out on the peristyle or colonnaded inner court. It was frequently decorated with busts or pictures of the family ancestors, and took the place of the modern, formal drawing room.

TABOR, a small town of Ceske Budejovice, Czech., on the Lužnice, 52 mi. S. of Prague, is mainly of historical importance since it was founded in 1420 by the more advanced Hussites, who came to be known as Taborites. On the summit of an isolated hill, separated from the surrounding country by the Lužnice and protected by marshes, the market place in the centre of the town is approached by narrow streets to render the approach difficult in wartime. In the market place stands a statue of Žižka, one of the most famous Hussite leaders. There also are the early 16th-century Gothic diaconal church and Gothic town hall with its museum of Hussite memorials. The surrounding district produces the hardier cereals and potatoes. Tabor is a railway junction and an industrial centre. Pop. (1950) 18,914.

TABRIZ, the chief city of East Azerbaijan and second city of Iran, is built at a height of 4,400 ft. in the valley of the river Aji Chai ("bitter water"), which flows westward to Lake Urmia. It is about 100 mi. from the Turkish and 60 mi. from the Soviet frontiers. Tabriz is situated in a pleasant fertile valley surrounded with gardens, but it lies in an earthquake zone and suffers frequent shocks of considerable intensity. The climate is continental with hot dry summers and cold winters. Pop. (1956) 289,996.

The early history of Tabriz (ancient Tauris) is unknown. It became the capital of the Armenian king Tiridates III in the 3rd century A.D. In A.D. 791 it was rebuilt by Zobeidah, wife of Harun al-Rashid, after being destroyed by an earthquake, but was again destroyed in A.D. 1042 with the loss of 40,000 lives. In the 13th century Tabriz resisted the Mongol invasions but was taken finally and became the Mongol capital under Khan Ghazan (*c.* 1295–1304). Its bazaars, mosques, walls and baths were extensively rebuilt at this time. In 1392 it was sacked by Tamerlane, but remained a provincial centre and soon regained its prosperity. About 30 years later the Turkomans made Tabriz their capital and Jahanshah built (1436–1467) the Masjiid i-Kubud ("Blue mosque") which is now partly ruined. It remained the capital under the first Safawid Shah Ismail I, but his successor moved to Kazvin which was less exposed to Turkish attacks. In the centuries that followed, Tabriz was the scene of constant warfare between the Turks, Russians and Persians, and changed hands several times. Russian troops occupied the town in 1900–05,

1909, 1914 and 1915–17, and again in 1941–45.

In 1721 and 1780 the town was wrecked by earthquakes and has been the scene of recurring epidemics of plague and cholera. In 1908 it was the starting place of the revolution against the Shah Mohammed II.

The only ancient buildings of note are the Blue mosque and the Ali Shah citadel (Arg) situated in the southwestern quarter of the town. The mosque, partly destroyed by earthquakes, has a blue tile decoration, one of the finest in Persia. The citadel walls are 25 ft. thick and stand some 120 ft. high. The ruins of Shanab-Ghazan, the royal resting place of Ghazan, are situated to the northwest of the town.

In the middle of the modern city there is a large public park called Gulistan garden, with pools, ornamental fountains and flower gardens, while 3 mi. outside the city, there is a large artificial pool called the King's lake (Shah Kouli). An island has been constructed there which, with its large restaurants, forms a summer resort for the inhabitants of Tabriz. Within the city many new buildings had been erected or were in the course of construction by the late 1950s; a number of these, including local government and other official buildings, are in the European style. Among those being built were the railway station, expected to be the biggest in Persia, and new buildings for the university which has schools of medicine, literature and agriculture.

The principal industry in Tabriz is carpet making; carpets are woven in the city, which is also the centre of trade for carpets woven in the surrounding villages of Azerbaijan. They form the bulk of exports from Tabriz. After weaving, the most important industries are the preparation of leather and the manufacture of shoes. Tabriz is also noted for its dried fruits and the manufacture of soap, paint and matches.

Tabriz is a road centre, and, after the completion of the railway from Tehran, will become a junction on the Asiatic-European route to Istanbul. An obstacle to the expansion of the city is the lack of good water; local water is brackish and supplies have to be piped a considerable distance.

See Sir Percy Sykes, *History of Persia* (1939).

(A. Kn.; M. V. S.-W.)

TABU. The basic meaning of the word tabu (taboo) in English is "forbidden," "prohibited," but it usually refers to actions barred by rules of manners or morals rather than of law; *i.e.*, by social convention in which there are some irrational elements. It has also been extended to apply to any ritual setting-apart of persons or things sacred or accursed.

Origin and Scope.—The term is of Polynesian origin. The form *tabu*, which Capt. James Cook noted when he first discovered its use at Tonga (Friendly Islands) in 1771, was later used by the Tongans when they adopted a written alphabet, but they later came to write the word as *tapu*. This is the most common Polynesian form with *kapu* as a variant, and various speculative etymologies have been given for the literal meaning; *e.g.*, *ta*, "to mark," "strike," *pu*, "exceedingly." In Melanesia, corresponding terms in form and meaning are *dabung* (Busama) and *tambu* (generally). The term and the concept are not always equivalent even in Polynesia: in Samoa, the notion of "forbidden" is expressed by *sa* and some similar Oceanic words have quite different meanings. *Tabu* in the Trobriands is a kinship term applying among others to a female cross-cousin or other relative appropriate for marriage, while in Dobu it means a magic charm to cause disfigurement or disease. On the other hand, notions very similar to tabu are found widespread ethnographically and expressed by a great range of linguistic expressions, as for example in Rhodesia by *tonda* among the Ila and *bwanga* among the Bemba, or *haram* in the Arabic-speaking world.

The concept of tabu was soon adopted into European languages and, by its suggestion of mystery and of being related to primitive religious ideas, provoked an extensive literature. A major contribution was made by Sir James Frazer in his article on "Taboo" in the 9th edition of the *Encyclopædia Britannica* (1875–89) and in *The Golden Bough* (1890). He regarded tabu as a system of religious prohibitions, attaining its fullest development in Polynesia but traceable under different names in most other parts of the world, and, as something sacred, he contrasted it with the concept of *noa* (a Maori word meaning "profane"). He also regarded tabu as the negative aspect of magic, the rules of prohibition as contrasted with the positive aspect of magic, the charms and formulas for securing success. Frazer gave an elaborate classification of things and acts tabooed and his work was valuable in bringing together a great mass of ethnographic information, in showing the range of the phenomenon and in stimulating enquiry into primitive religion, but his treatment was not sociological and many of his general ideas have not found modern support.

It should be emphasized that the meanings of tabu current in English and other western languages may be very different from those current in any one of the Polynesian or other communities in which the notion has been identified. Tabus have often been spoken of as if they were current for Polynesia as a whole. Frazer comments that "the rule which forbids persons who have been in contact with the dead to touch food with their hands would seem to have been universal in Polynesia." But, while this rule was valid for many Polynesian societies, it did not apply, *e.g.*, to Tikopia, where it was quite proper for someone who had handled a corpse to prepare and partake of food, even without washing his hands. Again, tabu has been treated as if it represented an integral, closely knit system of prohibitions, but this is not so even in any single Polynesian society. The range of items and activities to which *tapu* may be applied need have no consistent general pattern.

Nature and Functions.—One simple usage of *tapu* (in Tonga) is as a conventionalized expression of respect: at the beginning of a public address the speaker may say *Tapu mo hou 'eiki* ("My respects to the chiefs"). In conversation when something has been said which by Tongan ideas of propriety may perhaps be regarded as disrespectful or improper—such as a reference to a part of the human body or to an animal—the expression *Tapu mo koe* (equivalent to "If you will excuse my mentioning such a matter") is interpolated.

To modern Polynesians, *tapu* may mean no more than a thing which must not be interfered with. So a Tikopia man may tell his child not to touch a visitor's camera or fountain pen, saying "It is *tapu*," by which is meant not that the article in question has any particular quality of its own, but that interference with it is not allowed. Similarly in modern Melanesia a board set up on a tree with the word *tambu* on it may be simply a warning to people against going along a path or into an orchard, broadly equivalent to "Trespassers will be prosecuted."

But the notion of tabu is usually much more complex. Generically it includes the idea that the object or action interdicted has some ritual quality, or that the sanction against a breach of the rule is extra-human or supernatural. Very frequently this sanction is regarded as automatic in its action: a breach of tabu is followed logically and necessarily by some kind of trouble to the offender; *e.g.*, lack of success in fishing or hunting, sickness, death of a relative. In ordinary terms this would be regarded as accident or bad luck, but to the people concerned it is regarded as a punishment for breaking the tabu. A person meets with an accident or has no success in his pursuit and, in seeking for its cause, he or others infer that he has in some manner committed a breach of tabu.

With some tabus, however, the sanction is not automatic, but is invoked by the person controlling the tabu, and is believed to consist in the power of a god or spirit to punish the offender. From this point of view, Frazer's equation of tabu with negative magic is inadequate, according to his distinction between magic and religion, for this kind of tabu should come in the religious category. Another theoretical equation of tabu with negative *mana* (*q.v.*) by R. R. Marett, also fails. These two concepts in their Polynesian setting belong to different categories: standing for efficacy and power of a supra-normal kind, *mana* is not necessarily connected with tabu.

In general, tabu has a dual significance. Much attention has been paid to the apparent inconsistency between the notions of holiness or sacredness apparent in many kinds of tabu (the head of a Polynesian chief is tabu as part of his general character

as a sacred leader) and the notions of uncleanness in others (contact with a menstruating woman may be tabu in a defiling sense). But common to both these ideas is respect, associated with the idea of not touching. It is not true, as Frazer thought, that primitive peoples can make no moral distinction between the conceptions of holiness and of pollution, nor is it paradoxical that sacredness and prohibition should attach to the same object. Things which are sacred have some elements of prohibition attaching to them, but all things which are prohibited are not necessarily of sacred quality.

Tabus are often thought to be entirely irrational, even absurd, yet in some societies regular tabus have important social functions; *e.g.*, those against incest. Others have economic effects; *e.g.*, food tabus which restrict the diet of pregnant women or of totemic clans. Some kinds of tabu are not always in operation, but are set up for specific purposes; *e.g.*, those prohibiting fishing or picking fruit at certain seasons may be valuable in food conservation.

Many tabu rules have a social utility and, as a part of the general system of social control, may be a substitute for laws. They may also have importance as a system of prohibitions which forms part of the moral code of the society.

Theories.—There have been many attempts at explanations of the origin of such beliefs and behaviour. One of the most ingenious was that of Sigmund Freud, who associated the concept of tabu with that of neurosis. He believed that tabus were generated in ambivalent social attitudes in which the social components largely replaced the sexual elements of the neurosis. The basis of tabu then is a forbidden action for which there exists a strong inclination in the unconscious. But this ignores the fact that an essential feature of tabu is the obedience of the individual to restrictions imposed by social tradition. Moreover, much of the desire to break through the prohibitions of the tabu may be quite conscious *e.g.*, as, when tabus are placed upon food supplies. Understanding of unconscious factors may be very important—as in an explanation of incest tabu—but for the concept of tabu in its wider range this alone is inadequate.

Social anthropologists have not put forward a completely acceptable theory, but there is broad agreement that the tabus current in any society tend to relate to objects and actions which are significant for the social order. They may do this directly, as in emphasizing the status of chiefs and religious objects, or indirectly, as in the prohibitions on the killing or eating of totemic species which in themselves are of no particular significance but which, as indices of social units, form part of a symbolic framework for the society. It is not always possible to state why a certain action or article has been singled out for such respect behaviour, but a large number of tabus can be understood in such terms.

TABULARIUM, the technical name of the record office or national archives building of ancient Rome, which dominates the west end of the Forum. It is built along the side of the Capitoline hill and was bordered, on the side toward the Forum, by two stories of long arcades, the lower decorated with engaged Doric columns, and the upper with engaged Ionic columns. Each bay of the arcade is covered by a square, cloistered or four-sided vault. The tabularium is ascribed to Quintus Lutatius Catulus (*c.* 78 B.C.). It thus offers one of the earliest Roman examples of the use of engaged columns in connection with an arcade.

TABULATING MACHINES are mechanisms controlled by perforated cards which are used as mechanical aids to business methods. The first modern device of this class was designed for the automatic tallying or tabulation of statistics; but with extensive development modern tabulating machines are capable of automatically figuring and printing a report based on the information given to it in the form of perforations in cards or tape. Soon after the introduction of the Jacquard loom, in which the hooks lifting the warp threads were controlled by cards perforated to the desired pattern, Charles Babbage applied the principle to a calculating mechanism. Between 1834–54 he designed and partly built an "analytic engine" in which both the amount to be operated upon and the nature of the operation were entered by perforated cards. His machine was never completed. Development of the modern tabulating machine was accomplished by H. Hollerith.

Hollerith's first contribution was a means of tallying census returns through electrical reading of the data punched on cards and accumulating the totals in separate registers. The system was successfully used in the U.S. census of 1890. During the next decade notable improvements were made including automatic feeding of the cards under brushes for reading and a machine for sorting the cards rapidly into desired groupings. Consequently the 12th U.S. census in 1900 furnished particularly outstanding evidence of the possibilities of the system. The population volume was ready 1 year and 7 months from the start of enumeration; whereas it was estimated that hand tabulation of the 3 factors alone of sex, nativity and occupation would have required the services of 100 clerks for 7 years and 11 months. Since 1901 its commercial utility has been greatly increased. Whenever a transaction involves a number of amounts which are subsequently to be used as units two or more times in compiling various totals, it has been found to be generally economical to "translate" it on to a perforated card. If, for instance, the data connected with the cost of production of a certain part are recorded on a card this can then be used in computing totals of individual wages, department costs, machine costs, productive hours, etc. The tabulating method is now to be found in general use throughout the world.

The card upon which the data are recorded in the form of perforations has a column for each number or symbol to be entered. The digits 0 to 9 are denoted by holes punched proportionate distances from the bottom edge of the card starting with the 9 position. Above the 0 position is space for two additional perforations which are used principally for actuating certain control operations of the machine. These additional positions may also be used for special classification numbers, or, in combination with perforations in the regular digit position, to denote alphabetical characters. The card is divided vertically into "fields" each denoting a particular fact of the total information recorded. Certain information is descriptive while other is quantitative. The former class controls sorting and indicating, while the latter represents amounts to be totalled. Sorting and totalling are accomplished by different machines. Three separate mechanical devices are necessary to the system: a perforating machine or punch, a sorter and a tabulator. The ordinary form of perforating machine has a set of 12 punches under which the card is advanced a column at a time. By means of a skip bar or stops, certain fields can be skipped where no punching is to be done. There are also more complete types of perforating machines arranged to permit automatic duplication of information already on one card on to others, to "gang" punch any predetermined number of cards with identical data, to number cards consecutively as they are punched. The speed with which trained operators can perforate the cards depends on the nature of the information being recorded as well as its extent. An output of 350 punched cards per hour might be considered an average performance.

Sorting the cards into the desired groups for tabulation is done at the rate of about 400 cards per minute for each digit of the class number. One well-known form of sorting machine has 13 pockets, one for each possible columnar perforation and one for "rejects." The tabulator, or accounting machine, which totals the amounts perforated in given fields is capable of several different applications. The simplest form of this device consists of a set of counters actuated through a reading mechanism. Two methods of reading the cards are in use: electrical and mechanical. In the former, brushes make electrical contact through the perforations thereby actuating magnets to trip the counters. The mechanical method employs a full set of pins which are brought down upon the card momentarily at rest and which penetrate the perforations to actuate the counters mechanically. Printing tabulators are arranged to either total the cards at high speed—about 150 per minute—and then print the total, or list each card individually at slower speed followed by a total for the group. By means of special control features the machines automatically take totals of several fields after each sorted group and also store the amounts for grand totals. A great deal of flexibility is attainable in the way the

items and totals may be made to appear on the printed sheet. Mechanism has lately been incorporated accomplishing direct subtraction without the necessity of perforating the complements of the numbers as formerly required. This permits of reports showing total credit and debit amounts and net balance. By using combinations of two or more holes in a column it is possible to list alphabetical characters as well as numbers. With alphabetical printing, addition or subtraction automatically sensed by the machine and devices added to the printing section for handling report and bill forms, tabulating machines have become automatic accounting and billing machines. (B. To.)

TACANAN, a small group of tribes of South American Indians, constituting an independent linguistic stock. The Tacanas, from whom the stock takes its name, and their related tribes, live in northwestern Bolivia, in the region just east of Cuzco, on the upper Madre de Dios river and its tributaries, and extend eastward, between 13° and 15° S. lat., as far as the Beni. They are an agricultural as well as hunting and fishing folk, of the sedentary type, showing, apparently, considerable differences in cultural development between the different tribes. In spite of their close proximity to Cuzco, no significant study of this group has ever been made.

TACHEOMETRY, meaning "rapid measurement," is a method of surveying by rapid and indirect determination of horizontal and vertical distances to a point from an instrument station. The term is generally applied to operations in which distance is obtained by the measurement of a small angle lying opposite a short known base. Tacheometric instruments usually make use of a detached base; but, as in the case of the range finder (*q.v.*), the base line is sometimes an integral part of the instrument. Because of its size, the military range finder is not useful to the surveyor.

The instruments that make use of an external base may be divided into two groups: (1) those that make use of a fixed angle to measure an intercept on a distant staff, and (2) those that measure an angle subtended by a fixed base. In the latter case, the horizontal angle, subtended by a standard "subtense" bar of two metres and oriented at right angles to the line of sight, is measured on the circle of a theodolite. In the former case, the theodolite is equipped with stadia wires that intercept a portion of the length of a graduated rod held vertically at the distant point by two rays that include the fixed angle. A double-image type of tacheometer causes a portion of the image to be displaced with respect to another and the linear displacement is read on a horizontal graduated staff. The tacheometric instruments are generally theodolites or transits modified by the addition of the optical distance measuring devices and implemented by various self-reducing devices for finding the horizontal and vertical components of the slope distance.

See Range Finders; Surveying. (K. S. Cs.)

TACHINID FLY, the name given to any member of the family Tachinidae, of the order Diptera (*q.v.*). The tachinids play an extremely important part in keeping other insects under control and certain kinds have been transplanted from one country to another to help control imported and native pests. Among those imported into the United States is *Compsilura concinnata* for control of the gypsy moth; it attacks a large variety of native caterpillars; *Centeter cinerea* has been introduced from Japan for control of the Japanese beetle; *Microphthalma michiganensis* has been introduced into New Zealand from Canada for control of white grubs; *Archytas cirphis,* from Mexico to Hawaii for control of army worms; *Ptychomyia remota,* from Malaya to Fiji for control of *Levuana* caterpillars in Fiji. Many other successful importations have been made, but the great value of tachinids is found in their attacks upon native insects. They attack chiefly, caterpillars, beetle larvae and adults, sawflies, true bugs and earwigs. Their method of reaching the host is most varied; some scatter over grass thousands of eggs, which are eaten by the host; some lay eggs on the host, often inside it; some deposit living maggots, which attach themselves to passing victims. Those that lay eggs on adult beetles usually have a piercing ovipositor. Some tachinids are associated with army ants, apparently attacking insects fleeing the ants. Many species fly only at dusk, a few are nocturnal; most of them are sun lovers and are found on foliage; many visit flowers and are important in their pollination. The size ranges from three-eighths to three-quarters of an inch in length. While most are dull coloured, or shiny black, many are marked with red and yellow, and some are metallic green or blue. Some authors recognize several families and many subfamilies but there is no good way to separate them. The Dexiidae, with plumose arista, are the most frequently separated group.

The classification is highly technical and many of the species difficult to separate. The literature is voluminous and contained in many publications. The tachinids are one of the largest families of flies, more than 5,000 species being known from all parts of the world, and many new ones are added each year.

Bibliography.—For British species *see* C. J. Wainwright, "The British Tachinidae," in *Trans. Entomological Soc. of London* (1928); for European species *see* P. Stein, "Die Verbreitsten Tachiniden Mitteleuropas nach ihren Gattungen und Arten," in *Archiv fur Naturgesichta,* vol. 90 (1924). *See* also C. H. T. Townsend, *Manual of Myiology,* pt. i–xii (1934–44), containing keys and descriptions of families and genera of the world. (C. H. Cn.)

TÁCHIRA, a state in the Andean region of Venezuela bordering on Colombia. Area 4,286 sq.mi. Pop. (1950) 304,181; (1958 est.) 360,128. Agriculture dominates the economy and coffee and sugar are leading commercial crops. Rural industry, closely related to agriculture, is to a considerable degree carried on in homes. San Cristóbal, the state capital and leading commercial centre is on a trans-Andean highway about 34 mi. W. of the border town of San Antonio. Relatively large deposits of coal are found at Labatera. La Alguitrana claims the distinction of having the first oil well (1878–79) in Venezuela.

Certain inhabitants of Táchira belong to privileged groups who take great pride in the purity of their European ancestry. (J. J. J.)

TACHOMETER, an instrument that indicates the speed of rotation of a shaft or machine element. The major types of tachometers are classed as (1) centrifugal, (2) electrical, (3) vibrating reed and (4) electronic.

Centrifugal tachometers employ a spindle driven by the shaft whose speed is to be measured. As the spindle turns, centrifugal force causes fly-weights that are attached to the spindle to be displaced away from the axis of rotation. These weights are restrained by springs. The position of the fly-weights and the rotational speed of the shaft are interrelated. Through a suitable linkage the position of the weights is calibrated in terms of rotational speed and is indicated by a pointer which is on the instrument scale.

One type of electrical tachometer uses a small permanent-magnet-field direct current generator driven by the shaft whose speed is to be measured. As the voltage output of the generator is proportional to the speed of the shaft, a voltmeter, which can be remotely located, is graduated to indicate speed. Another electrical type uses a small ammeter actuated by the current flowing in a circuit due to the charging and discharging of a condenser. The instrument spindle, which is driven by the shaft, in turn drives a switch to open and close the circuit. The current flowing is proportional to the number of "makes" and "breaks" of the switch and the ammeter is graduated in revolutions per minute.

The vibrating reed type of tachometer uses a series of thin steel reeds with natural frequencies ranging from low to high and corresponding to certain speeds. When an instrument of this type comes into contact with the machine one or more of the reeds will vibrate in sympathy with the machine and indicate the rate of speed. Such a tachometer is not driven by the shaft but responds to vibrations of the machine.

Electronic tachometers are of two types. The strobotac employs the persistency of human vision to detect the change in speed viewed under a flashing light. When the flashes are synchronized with the shafts's rotational speed, the shaft appears stationary. There is no need for mechanical contact with the shaft. This feature is important for devices of very small power output, for contact between spindle and shaft actually slows down such machines. The other electronic-type tachometer is basically a revolution counter that receives its impulse from a pickup (often magnetic), counts the revolutions in each second and displays the count directly as revolutions per minute. (R. A. O.)

TACHYLYTE (TACHYLITE), in petrology the glassy variety of basic igneous rock such as basalt (*q.v.*) or diabase. Tachylytes are black in colour, with a pitchlike or resinous lustre, and in the thinnest sections are typically brown and translucent, the glass being crowded with granules of magnetite. They are found only under conditions which imply rapid cooling, and are much less common than the corresponding acid volcanic glasses, principally on account of the greater fluidity and greater power of crystallization which basic lavas possess. The principal mode of occurrence of tachylyte is as a chilled edge or selvage to thin dikes or sills of basalt or diabase. This edge may be only a fraction of an inch in thickness and merges inward into crystalline basalt. Tachylytes of this nature are common among the Tertiary igneous rocks of the Inner Hebrides of Scotland (Skye and Mull).

Exceptionally, tachylyte constitutes almost entire lava flows, as in the Hawaiian Islands. The rapid cooling of the highly fluid lavas of this region has inhibited crystallization, giving rise to vast floods of basaltic glass containing only minor amounts of crystalline material. Lastly, tachylytes occur as scoria, or bombs, thrown out by basaltic volcanoes. These are well known at Stromboli, Etna and in Iceland. Tachylytes readily undergo weathering and alteration, and are converted by oxidation and hydration into palagonite, a red, brown or yellow cryptocrystalline material. (C. E. T.)

TACITUS, CORNELIUS (*c.* 55–120), Roman historian, lived through the reigns of the emperors Nero, Galba, Otho, Vitellius, Vespasian, Titus, Domitian, Nerva, and Trajan. All we know of his personal history is from allusions to himself in his own works, and from 11 letters addressed to him by his very intimate friend, the younger Pliny. The exact year of his birth is a matter of inference, but it may be approximately fixed near the close of the reign of Claudius. Pliny indeed, though himself born in 61 or 62, speaks of Tacitus and himself as being "much of an age" (Pliny, *Epp.* vii.20), but he must have been some years junior to his friend, who began, he tells us, his official life under Vespasian (*Hist.* i.1), no doubt as quaestor, and presumably tribune or aedile under Titus (80 or 81), at which time he must have been 25 years of age at least. Of his family and birthplace we know nothing certain; we can infer nothing from his name Cornelius, which was then very widely extended; but the fact of his early promotion seems to point to respectable antecedents, and it may be that his father was one Cornelius Tacitus, who had been a procurator in one of the divisions of Gaul, to whom allusion is made by the elder Pliny in his *Natural History* (vii.76). But it is all matter of pure conjecture, as it also is whether his "praenomen" was Publius or Gaius. The most interesting facts about him to us are that he was an eminent pleader at the Roman bar, that he was an eye-witness of the "reign of terror" during the last three years of Domitian, and that he was the son-in-law of Julius Agricola. This honourable connection, which testifies to his high moral character, may very possibly have accelerated his promotion, which he says was begun by Vespasian, augmented by Titus, and still further advanced by Domitian, under whom we find him presiding as praetor at the celebration of the secular games in 88, and a member of one of the old priestly colleges, to which good family was an almost indispensable passport. Next year, it seems, he left Rome and was absent till 93 on some provincial business, and it is possible that in these four years he may have made the acquaintance of Germany and its peoples. His father-in-law died in the year of his return to Rome. In the concluding passage of his *Life of Agricola* he tells us plainly that he witnessed the judicial murders of many of Rome's best citizens from 93 to 96, and that being himself a senator he felt almost a guilty complicity in them. With the emperor Nerva's accession his life became bright and prosperous, and so it continued through the reign of Nerva's successor, Trajan, he himself, in the opening passage of his *Agricola*, describing this as a "singularly blessed time"; but the hideous reign of terror had stamped itself ineffaceably on his soul, and when he sat down to write his *History* he could see little but the darkest side of imperialism. He was an academic republican, like many of those who perished in that reign of terror. They were innocent in many cases of plotting against the emperor's life; and, no doubt, many of the plots were imaginary. But some had been real, and Domitian was determined to take no risks. Hence academic sympathizers with republican ideals fell under suspicion and were involved in the indiscriminate slaughter of those three years.

He was apparently convinced that Tiberius had been a ruler of the same type as Domitian; and that prejudiced him against the great, but grim, successor of Augustus. Moreover, some of the memoirs, contemporary with Tiberius' reign, were not likely to depict him in a favourable light, and on those Tacitus had largely drawn. (For the value of this evidence *see* Furneaux, Tac., Ann. vol. i. p. 20 *ad fin.* For Tacitus' judgment on Tiberius see *ibid.* Introduction ch. viii.) But, apart from personal prejudice, the Romans of the upper classes who lived in Rome or resorted thither tended to dislike imperial rule both socially and politically, and did, as a fact, see so much of the worst of it that they failed to appreciate the blessings it had conferred on the world outside. To his friend, the younger Pliny, we are indebted for the little we know about his later life. He was advanced to the consulship in 97, in succession to a highly distinguished man, Verginius Rufus, on whom he delivered in the senate a funeral eulogy. In 99 he was associated with Pliny in the prosecution of a great political offender, Marius Priscus, under whom the provincials of Africa had suffered grievous wrongs. The prosecution was successful, and both Tacitus and Pliny received a special vote of thanks from the senate for their conduct of the case. It would seem that Tacitus lived to the close of Trajan's reign, as he seems (*Ann.* ii.61; iv.4) to hint at that emperor's extension of the empire by his successful Eastern campaigns from 115 to 117. Whether he outlived Trajan is a matter of conjecture. It is worth noticing that the emperor Tacitus in the 3rd century claimed descent from him and directed that ten copies of his works should be made every year and deposited in the public libraries. He also had a tomb built to his memory, which was destroyed by order of Pope Pius V. in the latter part of the 16th century.

Pliny, as we see clearly from several passages in his letters, had the highest opinion of his friend's ability and worth. He consults him about a school which he thinks of establishing at Comum (Como), his birthplace, and asks him to look out for suitable teachers and professors. And he pays (*Epp.* vii.33.) him the high compliment, "I know that your *Histories* will be immortal, and this makes me the more anxious that my name should appear in them."

The following is a list of Tacitus' remaining works, arranged in their probable chronological order, which may be approximately inferred from internal evidence:—(1) the *Dialogue on Orators*, about 76 or 77; (2) the *Life of Agricola*, 97 or 98; (3) the *Germany*, 98, published probably in 99; (4) the *Histories* (*Historiae*), completed probably by 115 or 116, the last years of Trajan's reign (he must have been at work on them for many years); (5) the *Annals*, his latest work probably, written in part perhaps along with the *Histories*, and completed subsequently to Trajan's reign, which he may very well have outlived.

The *Dialogue on Orators* discusses, in the form of a conversation which Tacitus professes to have heard (as a young man) between some eminent men at the Roman bar, the causes of the decay of eloquence under the empire. There are some interesting remarks in it on the change for the worse that had taken place in the education of Roman lads. The style of the *Dialogue* is far more Ciceronian than that of Tacitus' later work, and critics have attributed it to Quintilian; but its genuineness is now generally accepted. It is noticeable that the mannerisms of Tacitus appear to develop through his lifetime, and are most strongly marked in his latest book, the *Annals*.

The *Life of Agricola*, short as it is, has always been considered an admirable specimen of biography. The great man, with all his grace and dignity, is brought vividly before us, and the sketch we have of the history of Britain under the Romans gives a special interest to this little work.

The *Germany*, the full title of which is "Concerning the geog-

raphy, the manners and customs, and the tribes of Germany," describes with many suggestive hints the general character of the German peoples and dwells particularly on their fierce and independent spirit, which the author evidently felt to be a standing menace to the empire. The geography is its weak point; much of this was no doubt gathered from vague hearsay. Tacitus dwells on the contrast between barbarian freedom and simplicity on the one hand, and the servility and degeneracy of Roman life on the other.

The *Histories,* as originally composed in 12 books, brought the history of the empire from Galba in 69 down to the close of Domitian's reign in 97. The first four books and a small fragment of the fifth, giving us a very minute account of the eventful year of revolution, 69, and the brief reigns of Galba, Otho, and Vitellius, are all that remain to us. In the fragment of the fifth book we have a curious but entirely inaccurate account of the Jewish nation, of their character, customs and religion, from a cultivated Roman's point of view, which we see at once was a strongly prejudiced one.

The *Annals*—a title for which there is no ancient authority, and which there is no reason for supposing Tacitus gave distinctively to the work—record the history of the emperors of the Julian line from Tiberius to Nero, comprising thus a period from A.D. 14 to 68. Of these, nine books have come down to us entire; of books v., xi. and xvi. we have but fragments, and the whole of the reign of Gaius (Caligula), the first six years of Claudius, and the last three years of Nero are wanting. Out of a period of 54 years we thus have the history of 40 years.

The principal mss. of Tacitus are known as the "first" and "second" Medicean—both of the 10th or 11th centuries. The first six books of the *Annals* exist nowhere but in the "first Medicean" ms., and an attempt was made in 1878 to prove that the *Annals* are a forgery, by Poggio Bracciolini, an Italian scholar of the 15th century, but their genuineness is confirmed by their agreement (*see* Introduction to vol. i., of Furneaux's edition of the *Annals* of Tacitus, Clarendon Press series, 1884) in various minute details with coins and inscriptions discovered since that period. Moreover, Ruodolphus, a monk, writing in the 9th century, shows that he is acquainted with a ms. of Tacitus containing at least the first two books. Add to this the testimony of Jerome that Tacitus wrote in 30 books the lives of the Caesars and the evidence of style, and there can be no doubt that in the *Annals* we have a genuine work of Tacitus.

Much of the history of the period described by him, especially of the earlier Caesars, must have been obscure and locked up with the emperor's private papers and memoranda. As we should expect, there was a vast amount of floating gossip, which an historian would have to sift and utilize as best he might. Tacitus, as a man of good social position, no doubt had access to the best information and must have talked matters over with the most eminent men of the day. There were several writers and chroniclers, whom he occasionally cites but not very often; there were memoirs of distinguished persons—those, for example, of the younger Agrippina, of Thrasea, and Helvidius. There were several collections of letters, like those of the younger Pliny; a number, too, of funeral orations; and the "acta senatus" and the "acta populi" or "acta diurna," the first a record of proceedings in the senate, the latter a kind of gazette or journal. Thus there were the materials for history in considerable abundance, and Tacitus was certainly a man who knew how to turn them to good account. He has given us a striking, and on the whole doubtless a true, picture of the empire in the 1st century. The rhetorical tendency which characterizes the "silver age" of Roman literature gives perhaps exaggerated expression to his undoubtedly strong sense of the badness of individual emperors, but he assuredly wrote with a high aim, and we may accept his own account of it (*Ann.* iii., 65): "I regard it as history's highest function to rescue merit from oblivion, and to hold up as a terror to base words and actions the reprobation of posterity." He is convinced of the degeneracy of the age, though it be relieved by the existence of truly noble virtues; and he connects this degeneracy more or less directly with the imperial régime. But it is difficult to dogmatize as to Tacitus' political ideals. He is primarily concerned rather with ethics than with politics; though he may feel that the world is out of joint—with whatever sentimental sympathy he may regard the age of "liberty" and admire the heroic epoch of the republic—yet he appears to realize that the empire is a practical necessity, and to the provinces even a benefit. Like the Stoics, with whom otherwise he has little in common, he censures rather individual rulers than the imperial system. But "the key to the interpretation of Tacitus," it has been well said, (Dill, *Roman Society from Nero to Marcus Aurelius,* Bk.i.ch.1.) "is to regard him as a moralist rather than a politician." Perhaps the strongest work in the *Annals* and *Histories* is the delineation of character.

Tacitus gives us no certain clue to his religious belief. His expressions of opinion about the government of the universe are difficult to reconcile with each other. There seems to have been a strange tinge of superstition about him, and he could not divest himself of some belief (*Ann.* vi. 21,22.) in astrology and revelations of the future through omens and portents, though he held these were often misunderstood and misinterpreted by charlatans and impostors. On the whole he appears to have inclined to the philosophical theory of "necessitarianism," that every man's future is fixed from his birth; but we must not fasten on him any particular theory of the world or of the universe. Sometimes he speaks as a believer in a divine overruling Providence, and we may say confidently that with the Epicurean doctrine he had no sort of sympathy.

Tacitus' style is discussed in the article LATIN LANGUAGE. Whatever judgment may be passed on it, it is certainly that of a man of genius, and cannot fail to make a deep impression on the studious reader. Tacitean brevity has become proverbial, and with this are closely allied an occasional obscurity and a rhetorical affectation which his warmest admirers must admit. He has been compared to Carlyle; and both certainly affect singularity of expression. But they are alike only in the brevity of sentences; and the brevity of Carlyle is not that of an artist in epigram. Tacitus was probably never a popular author; to be understood and appreciated he must be read again and again, or the point of some of his acutest remarks will be quite missed.

Tacitus has been many times translated, in spite of the very great difficulty of the task; the number of the versions of the whole or part is stated as 393.

Murphy's translation (we should call it a paraphrase) was for long one of the best known; it was published early in the 19th century. On this was based the so-called Oxford translation, published by Bohn in a revised edition. Messrs. Church and Brodribb's translation and Professor Ramsay's (1904) (the latter of *Annals* i.–iv.) are much better. Of the many commentaries *see* Ritter's (1864); Nipperdey's (1879); Heräus's (*Histories,* 1885); Furneaux's (*Annals,* i. vi., 1884; xi.–xvi. 1891; *Germania,* 1894); Spooner's (*Histories,* 1891). The last two editors' introductions are particularly useful. By far the best edition of the *Agricola* in English is that of Furneaux as revised by Anderson (Clarendon Press, Oxford). Of works relating to Tacitean Latinity, Draeger's *Syntax und Stil des Tacitus* is the best.
(W. J. Bk.; X.)

TACITUS, MARCUS CLAUDIUS, Roman emperor from Sept. 25, A.D. 275 to April 276, was a native of Interamna (Terni) in Umbria. In the course of his long life he held various civil offices, including that of consul in 273. Six months after the assassination of Aurelian he was chosen by the senate to succeed him, and accepted by the army. During his brief reign he set on foot some domestic reforms, and sought to revive the authority of the senate, but, after a victory over the Goths in Cilicia, he succumbed to hardship and fatigue (or was slain by his own soldiers) at Tyana in Cappadocia. Tacitus, besides being a man of immense wealth (which he bequeathed to the state), had considerable literary culture, and claimed descent from the historian.

TACNA, department of Peru, to which by the terms of the 1929 settlement of the Tacna-Arica question it was transferred by Chile. Bounded north by Moquegua and Puno, east by Bolivia,

south by Tarapacá, Chile, west by the Pacific. Area 5,701 sq.mi. Pop. (1958 est.) 51,920. It belongs to the desert region of the Pacific coast. There are a few fertile spots near the mountains, where mountain streams afford irrigation and drinking water. Few of its streams cross the entire width of the department; most are lost in desert sands. The department is part of the former area, Tacna and Arica, which once formed part of the Peruvian department of Moquegua. Its capital is Tacna (pop. 1958 est. 17,230), a small inland town 48 mi. by rail from Arica, in a fertile valley among the foothills of the Andes.

TACNA-ARICA DISPUTE, a controversy involving title to territory that belonged to Peru before the War of the Pacific (*q.v.*). The treaty ending the conflict between Chile and Peru in 1883 provided that Tacna-Arica should be governed by Chile for a period of 10 years and at the end of that time a plebiscite should be taken to decide title to the territory, the party suffering loss of the territory to receive $10,000,000 from the other. Failure to agree on terms of the plebiscite ended in the breaking off of negotiations many times—in 1893, 1901, 1905, 1910 and 1913. In July 1922 the two parties accepted U.S. Pres. Warren G. Harding as arbitrator. After Harding's death, Pres. Calvin Coolidge took the responsibility. In 1925 he recommended that the plebiscite be held and for this purpose named a commission headed by Gen. John J. Pershing. The commission went to the area but failed to work out a solution. Following this failure, the proposal by the U.S. secretary of state, Frank B. Kellogg, that Tacna-Arica be ceded to Bolivia was accepted by Chile but rejected by Peru. In July 1928 Chile and Peru resumed direct negotiations and on Feb. 21, 1929, reached a settlement providing that Tacna should go to Peru and Arica to Chile. Chile agreed to pay Peru $10,000,000 and to carry out certain construction works in the city of Arica. *See* also ARICA; TACNA. (J. J. J.)

TACOMA, a city in western Washington, U.S., a port of entry and the seat of Pierce county, is located on Commencement bay, head of navigation on Puget sound, at the mouth of the Puyallup river, 30 mi. S. by water of Seattle. From Tacoma can be seen Mt. Rainier, 50 mi. E. (*see* MOUNT RAINIER NATIONAL PARK); via the Narrows bridge the city has easy access to the Olympic National park (*q.v.*).

From Commencement bay in 1841 Lt. Charles Wilkes, commander of a U.S. exploring expedition, launched the first survey of the Pacific Northwest. Wilkes commented in his official journal upon the surrounding waterways: "Nothing can exceed the beauty of these waters, and their safety . . . I venture nothing in saying, there is no country in the world that possesses waters equal to these."

Except for the activities of the Hudson's Bay company at Fort Nisqually, there was little in the way of white settlement of the area before 1868. In that year, its original name—Commencement City, after the bay which Wilkes described—was changed to Tacoma, when Gen. Morton Matthew McCarver platted a new city in anticipation of its selection as the western terminus for the Northern Pacific railway. The new name was a corruption of "Tahoma," the Indian name for Mt. Rainier.

Tacoma was incorporated as a city in 1875 under the laws of Washington territory. It operates under a council-manager form of government in effect since 1953. Its population of 147,979 in 1960 was about 95% white; many of its citizens are of Scandinavian heritage, typical of the coastal cities of Washington. Tacoma is the central city of a standard metropolitan statistical area comprising Pierce county, with a population in 1960 of 321,590, a gain of 16.6% in the decade. (For comparative population figures *see* table in WASHINGTON: *Population.*)

Tacoma's principal manufactures include lumber and lumber products, aluminum, copper and copper by-products, ferroalloys, castings and mineral wool. Two large electrochemical plants produce caustic and chlorine. Several candy manufacturers ship nationally and overseas, and the city has a large men's wearing apparel plant. Heavy cranes and logging equipment are manufactured to supply the needs of forest industry. Boatbuilding yards produce fishing boats and pleasure craft as well as watercraft to supply the armed services, marking Tacoma as one of the largest boatbuilding centres on the Pacific coast. Several major armed services installations, including Fort Lewis, McChord air force base and Madigan army hospital, were established nearby.

The University of Puget Sound (Methodist, founded 1888) and Pacific Lutheran university (established 1890) are located in the Tacoma area. The city also serves as headquarters for the Washington State Historical society, whose five-floor museum overlooks Commencement bay. Tacoma's public library system embraces a main library, branch libraries, a library service station and bookmobile service. The city maintains over 35 parks, comprising a total of more than 1,700 ac.; the largest is Point Defiance park, whose grounds contain not only a public yacht basin, a zoo and landscaped gardens but also the restoration of old Fort Nisqually. (B. M. L.)

TACONITE. The name taconite was applied originally to an iron-bearing formation of supposedly Taconic age (Cambrian to Ordovician). Though this was an error the name was associated thereafter with iron-bearing rocks on the Mesabi range in northern Minnesota consisting of chert (fine-grained quartz), magnetite, haematite, several silicates as minnesotaite, greenalite, stilpnomelane and amphibole and siderite. The rocks were originally chemical precipitates which now form beds of a maximum thickness of 750 ft. and a length of about 100 mi. along the strike. Their extent down the dip is unknown. In this taconite are found the high-grade iron-ore bodies which have supplied most of the iron of the U.S. As all taconite contains on an average 27% of chemically combined iron, it is considered the largest potential reserve of ore in the U.S. About 5,000,000,000 to 6,000,000,000 tons of it are near enough to the surface and contain sufficient amounts of magnetite so that its concentration to a high-grade product was in an advanced stage of development by the second half of the 20th century, and shipments of taconite concentrate and agglomerate were being made.

TACTICS. Tactics is the art and science of fighting battles. It is concerned with the approach to combat, the disposition of troops, the use made of various arms and the execution of movements for attack or defense. It is distinguished from strategy, in a military sense, which may be shaped by political and economic as well as purely military factors. Strategy consists of planning for the war as a whole, the disposition of forces among the theatres of operation and the direction of the campaigns leading up to battle (*see* STRATEGY). Karl von Clausewitz, the 19th-century Prussian military theorist, defined tactics as "the formation and conduct of single combats in themselves" and strategy as "the combination of single combats with each other. . . . In other words, strategy forms the plan of the war, maps out the proposed course of the various campaigns which compose the war and regulates the battles to be fought in each." (*On War*, trans. by J. J. Graham, vol. i, p. 86, Kegan Paul, Trench, Trubner, London, 1911.)

No matter how precisely the two terms may be defined, however, there is seldom any fixed line of demarcation. Military analysts themselves are at odds as to where the one leaves off and the other begins. Strategy is frequently limited by the tactical potentialities of the forces involved, and tactics in turn depend on such strategic considerations as the planning and conduct of campaigns. Actually, the two overlap more often than not. In recognition of this fact, the term "grand tactics" gained currency during the Napoleonic era to denote the transition from strategy to tactics, and 20th-century military commentators have used the phrase "operational strategy" to describe concentrations of such major units as corps and divisions in preparation for battle.

Designations of this sort, unfortunately for clarity, are the exception. As a rule, the student of war must appraise each operation individually and supply his own distinctions.

Following a discussion of the elements of tactics, the principles, tactical formations, attack and offensive and defensive tactics, this article is divided into the following sections:

I. Tactics of the Ancient World
1. The Greek Phalanx

2. The Tactics of Epaminondas
3. The Graeco-Macedonian Tactical System
4. World Conquest
5. The Rise of Rome
6. The Battle of Cannae
7. Tactics of the Cohorts
8. Tactics of the Empire
II. The Cavalry Cycle
1. The Byzantine Horse-Archer
2. The Byzantine Tactical System
3. Tactics of the Franks
4. The Decline of Infantry
5. Medieval Tactics of Europe
6. Longbow and Halberd
7. Early Victories of Gunpowder
III. The Military Renaissance
1. The Fall of Constantinople
2. Pike and Arquebus
3. Maurice of Nassau
4. Gustavus Adolphus and the Thirty Years' War
IV. The Age of Linear Tactics
1. The New Age of Moderation
2. The Wars of Louis XIV
3. The Tactical Theories of Marshal Saxe
4. Frederick the Great
V. Napoleon and 19th-Century Tactics
1. The American Revolution
2. French Revolutionary Tactics
3. Bonaparte's Early Victories
4. Tactics of the Empire
5. Wellington's Tactics
6. Half a Century of Tradition
7. The American Civil War
VI. World War I
1. The Battle of the Marne
2. Deadlock on the Western Front
3. The Offensives of 1917
4. The Mobile Warfare of 1918
VII. World War II
1. The Post-World War I Reaction
2. Early German Victories
3. The War in the Pacific
4. U.S. Amphibious Victories
5. Wide Variety of World War II Tactics
VIII. The Korean War
1. Intervention in Korea
2. Tactical Innovations of Korea
3. Tactics of the Atomic Age

Opposite Poles of Tactics.—The elements of tactics are dual in character. Attack and defense, cohesion and dispersion, protection and mobility, missile and shock effect, moral and material values—these elements have been changeless throughout the ages, regardless of variations in arms and communications. The barbarian's bow and arrow was as legitimate a missile weapon as the machine gun, and elephants were esteemed for shock effect many centuries before the invention of the tank.

Seldom do armies decide arbitrarily on the tactics they will adopt. The swing from one pole to another is nearly always influenced by geographical, climatic and economic factors. Nomads of the plains become cavalry warriors from necessity rather than choice, just as mountaineers fight on foot. Emerging tribes and nations, unsure of their military skill, were drawn toward the cohesion of the human wall, or phalanx. As such peoples grew in strength and confidence they tended to adopt formations of dispersion, which are better suited to aggression. Thus the Romans of the early city-state fought in an eight-rank phalanx, but the Romans of the conquering republic developed that marvelously flexible tactical instrument known as the legion (*q.v.*).

One of the most cherished delusions of the ancient world was the belief that a formation had a shock effect in proportion to its depth. But adding ranks to the phalanx did not add to the material might of the attack; it merely contributed to the moral impetus of the attackers. Shock effect is rarely the product of an actual physical impact. The shock is communicated to the soldier's mind rather than his body, and during the cavalry age he was morally defeated by his dread of being trampled, though horses seldom ran down foot soldiers who stood their ground.

Principles of Tactics.—Basic tactical principles are few and simple. The complexity and difficulty appear when such principles as surprise, secrecy, deception, security and the gathering of intelligence are put into actual practice.

So obvious are the tactical advantages to be gained by deception and surprise that they are sought instinctively by savages. Both principles are combined in that most primitive of tactics, the ambush. Not only savages but even wild animals know enough to hide while lying in wait to attack. Yet the ambush is one of the most effective tactics of 20th-century warfare; it was used by both British and German armoured columns in the complicated North African desert campaigns of World War II.

It is hardly necessary to add that surprise depends on the degree of secrecy with which a general masks his intentions and capabilities. The moral turning point of the American Revolution came in 1776 when George Washington crossed the ice-choked Delaware river with a supposedly beaten army and killed or captured nearly all troops of three German mercenary regiments sleeping off a Christmas celebration at Trenton. This surprise would not have been possible without the American general's accurate intelligence of the enemy's vulnerability. Nor could it have occurred if the German officers had enforced security precautions in keeping with the defense of an outpost. A famous example of tactical deception was provided a week later when Washington cheated the British of an almost certain victory. Trenton was the locale again as Lord Cornwallis brought his adversary to bay with a materially superior army. A British attack had been ordered for the following morning, but the Americans left their campfires burning and slipped away in the darkness. Cornwallis' first intimation of the escape came at daybreak when he heard cannonading ten miles in his rear as Washington defeated a detachment of British reinforcements in the small battle of Princeton.

So essential is intelligence to the tactician that a good spy is sometimes worth more to an army than a good general. Reconnaissance patrols, prisoner interrogations and observation or listening posts also play an important part in arriving at an estimate of an enemy's intentions and capabilities.

Security, like secrecy, is maintained in all military ages by means of eternal and unremitting vigilance. Although the firepower of missile weapons has often been given the sole credit for the prolonged stalemate in World War I, violation of age-old principles of tactics cannot be overlooked. Several promising Allied offensives met failure because surprise and deception were sacrificed to make possible the tremendous artillery "preparations" which had no decisive effect on an enemy burrowed deep into the earth. Such large quantities of shells were required for these bombardments that the area and extent of the impending offensive were revealed to the enemy by aerial photographs of ammunition dumps.

The plain lesson of history is that improvements in weapons and tactics cannot compensate for flaunting basic tactical principles.

Tactical Formations.—Far back in the racial past the most intelligent of our primitive ancestors perceived that superior numbers did not always make for superior force. A great deal depended on the tactical direction and speed with which this force was applied, and the solution was to group fighting men so that they could give one another the most support while doing the most harm to the enemy. This was the beginning of tactical wisdom.

The two basic formations are the line and the column, which differ only by 90° of the compass. In other words, a column of men in four files, facing north, has only to execute a "right face" to become a line of four ranks, facing east.

Neither of these formations is useful for all tactical purposes. Although the column is best adapted to marching and maneuver, its narrow front and vulnerable flanks are liabilities in combat. The line lacks depth and mobility, but it is more suitable for deployment on the battlefield. Mention should also be made of two other formations which appear less frequently in the chronicles of war—the hollow square and its counterpart, the 360° perimeter. Some stout stands have been made by men facing outward in all directions, but the defect of such formations is that ability to maneuver is sacrificed.

In the prehistoric past it was evident that forming warriors into a line or column was not enough. Some attention also had to be paid to problems of deploying them so as to make the best

of both shock and missile weapons. When men learned to fight on horseback, a cavalry arm came into being. The "eyes" of the primitive army, when used for scouting and reconnaissance, horsemen were also effective for pursuing a broken foe. A crude artillery arm appeared as early as the 8th century B.C., when the Old Testament dates engines of war (*q.v.*). Not even the tactical ancestor of the tank was lacking in the ancient world. Armoured chariots manned by archers and spearmen led the infantry attack in the battles fought on the plains of Mesopotamia, as depicted by bas-relief friezes dating back many centuries before the Christian era.

The Tactics of Attack.—Descriptions of battles are apt to give the impression that victories are won entirely by physical pressure, as measured by the casualties inflicted. It has been the experience of history, on the contrary, that moral forces play a much larger part in the outcome than material means. An army's combative spirit is not often broken because the ranks have been so thinned that the survivors are crushed by sheer human tonnage. They are beaten because of their conviction that further resistance is hopeless, and it is the business of the tactician to convince rather than crush his opponents.

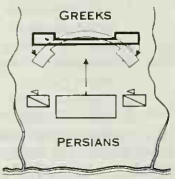

FIG. 1.—BATTLE OF MARATHON (490 B.C.), SHOWING TACTICS OF CONCENTRIC ATTACK

The test may be found in the fact that casualties of 30% are usually the most an army can endure without losing combative spirit. Yet seven men out of ten are still able to fight, and it may be that they outnumber the entire force of adversaries who accepted battle with a numerical disadvantage. History records instances of losers being routed while still possessing a two-to-one numerical superiority. They were not crushed; they were simply convinced.

The methods of creating a conviction of defeat may be reduced to a few plans of attack which repeat themselves throughout history. Most simple of all is the plain frontal assault all along the line. Justifiable and even desirable under some circumstances, it is as a rule the resort of unimaginative generalship. As for the direct rear attack, it is so rare as to be associated only with ambush or pursuit.

At an early age it was discovered that armies, like the individuals composing them, dread an attack from the flank or rear. An assault from one side or another is not enough, since an adversary can face in the new direction, whereupon the effort becomes a mere frontal attack. In order to deliver a true flank attack, part of the offensive force must fix the enemy's front, perhaps even defensively, while the assault force swings around to strike simultaneously from the side. If this force can make a wide enough swing to threaten an opponent's rear, the attack becomes a single envelopment. And in instances when the rear is assailed from both sides with concentric thrusts, a double envelopment is the result. Neither a flank attack nor envelopments may be possible when a general secures his flanks with natural obstacles. In that case it is sometimes possible to create two new flanks by rupturing an adversary's front and driving through the gap to strike at his rear. That is the battle of penetration and it has some distinguished victories to its credit.

In any event, the effectiveness of the attack is in direct proportion to the conviction of defeat it can instill. As evidence, history is filled with occasions when the casualties of a beaten army were the result rather than the cause of defeat.

Offensive and Defensive Tactics.—The relative merits of the offensive and defensive have been subjects of argument in all military ages. From one century to another each has dominated in turn, the new cycle being brought about by the introduction of new weapons or tactics.

The attacker is usually able to choose the time of the assault and sometimes the place as well. If there are several points where the blow might fall, he has an opportunity to utilize the principles of deception and surprise against an opponent who must prepare as best he can to meet every alternative.

The defender often has the advantage of choosing and fortifying his own ground, but at least temporarily he must concede the initiative to the enemy. In most instances, of course, he expects to regain it by means of a decisive counterattack after exhausting his adversary or placing him in an unfavourable position. Passive defenses are seldom the resort of a general who retains freedom of action, though there are exceptional occasions when the object is to inflict crippling casualties on a rash enemy.

Cordon defenses are put into effect along a frontier where troops can be thinly dispersed and quickly reinforced by reserves in the event of trouble. The mobile, or elastic, defense is based on the theory that if the enemy makes a penetration his flanks will be open to counterattack. As for the so-called defensive-offensive action, it merely implies that the defender has planned from the beginning to launch a counterstroke when he has an opportunity.

Breaking off contact with the enemy is a delicate operation calling for that specialized form of the defense known as a delaying action. The rear guard force holds just long enough to compel the pursuer to deploy, then pulls back to the next prepared position before becoming seriously engaged. In a two-line delaying action the first and second lines retire through each other in turn until the main body of troops is out of danger.

The ideal instrument would be an army equally formidable in offensive and defensive tactics, but there have been few such in military chronicles. Probably the most effective combination throughout history has been the strategic offensive and tactical defensive. Invading armies are often able to choose their ground and await an attack, since the enemy is obliged for the sake of national morale to defend the homeland. No better example of this compulsion could be found than the situation faced by Roman generals after Hannibal's crossing of the Alps into Italy (*see* HANNIBAL). One after another, they met him in headlong attack, only to go down to crushing defeat. Finally the proud republic was reduced to avoiding battle in order to recuperate.

Whenever the balance between offensive and defensive tactics is tipped too far in either direction, the social progress of the age is affected. In the 13th century the Mongol horsemen who overran Asia left desolation and anarchy in the wake of an irresistible offensive. Meanwhile, with fortification holding the advantage over siegecraft in western Europe, the consequences of an all-powerful defensive were political and economic stagnation.

Until the 19th century, offensive and defensive cycles were of long duration. Improvements in weapons have come so rapidly since the Napoleonic era that the swing from one to another is a matter of only a few years. Generals of all armies were confident at the outbreak of World War I that the offensive power of the arms of 1914 would prevail in a few months. But missile weapons favour the defensive, as a rule, and the machine gun had the leading part in turning the conflict into a stalemate. Not until the last few months of the war did the tank provide the victors with an offensive weapon capable of breaking the deadlock. Even so, a school of military thought held after the war that the defensive remained powerful enough to curb an aggressor in the next conflict. Thus, it was a sad disillusionment when the German armies of 1940 drove on to a succession of early victories.

I. TACTICS OF THE ANCIENT WORLD

1. The Greek Phalanx.—Two great tactical systems, the Graeco-Macedonian and the Roman, dominated the ancient world (*see* ARMY). Citizen-soldiers of the Greek city-states fought in an eight-rank phalanx of heavy infantry supported by contingents of light foot. Although the *Iliad* mentions horse and chariots a millennium before the Christian era, cavalry was not an arm suited to a mountainous peninsula, and the incessant strife of the city-states was usually decided by the clash of opposing hedges of infantry spears.

Greek warfare was distinguished more for brawn and fortitude than the intellectual brilliance which made for greatness in other directions. Even the double envelopment which won the battle of Marathon (*see* fig. 1) for the Greeks in 490 B.C. seems to have been the product of a fortuitous accident rather than generalship.

Attacking at a fast pace, before the Persian superiority in cavalry and missile weapons could become effective, the Greek *hoplites* (heavily armed infantrymen) of both wings hurled back the lightly armed invaders in their path. Meanwhile, their own hard-pressed centre gave ground before the enemy advance until it seemed that defeat was imminent. As it proved, this withdrawal created the opportunity for the heavy infantry of the Greek wings to converge on the flanks and rear of the Persian host. Thus the battle ended with the demoralization and rout of an army which probably outnumbered the Greeks at least two to one.

2. The Tactics of Epaminondas.—Defending their homeland against the Persians, the Greeks learned to place increased reliance on cavalry and missile weapons—mercenary horsemen from the plains of Thessaly and bowmen from Crete. The first Greek to distinguish himself as a tactician was Epaminondas (*q.v.*) in 371 B.C. Facing a Spartan army of 10,000 men with a force of 4,000 which included undependable allies, the Theban commander drew up a strange oblique order of battle by advancing his left wing and reinforcing it with his best troops to a depth of 48 ranks (*see* fig. 2). On the other wing he placed his doubtful allies. The battle of Leuctra opened with a cavalry clash won by the better-trained Theban horse. Then Epaminondas bore down with the infantry of his heavy left wing on the right of the Spartan phalanx, and the moral factor of surprise probably had more to do with the outcome than physical shock. At any rate, the Spartan right recoiled in disorder on its own centre, and a phalanx thrown into confusion was little better than a mob. The muscular tactics of Sparta were of no avail to demoralized men too crowded together to use hand weapons, and the Thebans gained a one-sided victory.

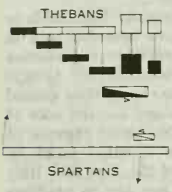

FIG. 2.—BATTLE OF LEUCTRA (371 B.C.), SHOWING TACTICS OF THE OBLIQUE ORDER

Epaminondas received a mortal wound while winning a second battle with his oblique order, and it remained for a barbarian prince to assemble the tactics of the disputatious Greeks into a system capable of conquering the world. Young Philip of Macedon was an attentive student of Epaminondas' methods while spending three years in Thebes as a hostage (*see* PHILIP II [of Macedonia]). He returned to his northern kingdom to organize the first army of ancient history to combine effectively such arms as infantry, cavalry and artillery.

3. The Graeco-Macedonian Tactical System.—The new tactical system was built about the phalanx. Philip strengthened the mobile human fortress by doubling the eight-rank formation of the Greeks and arming his warriors with a longer and heavier spear. He perceived that the two chief weaknesses of the phalanx were the vulnerability of its flanks and the inability to maneuver or even retain its solidarity on rough ground. As a tactical remedy for both defects, he organized and trained a light infantry such as the ancient world had never known before—a disciplined force of archers, slingers and javelin men. Their function was to act as tactical hinges on both sides of the phalanx, lending mobility as well as protection. Since the young nobles of Macedonia preferred to fight on horseback, Philip had no difficulty in organizing a heavy cavalry arm far superior to the establishments of the Greek city-states. Squadrons of light horse were also employed for scouting and skirmishing.

That the army had an efficient baggage train, medical corps and engineering section is evident from its accomplishments. In his development of "artillery," moreover, the Macedonian king went far beyond his predecessors who had found war engines useful only for siegecraft (*see* ENGINES OF WAR). He originated the idea of carrying only the essential parts on the march and depending on his engineers to cut timbers for the framework whenever needed.

On the battlefield the full phalanx of about 8,000 heavily armoured spearmen was doubtless a fearsome spectacle as it advanced with menacing steel points. Several such bodies of troops might be employed as the central bulwark of the battle line, the pivot either of offense or defense. On the wings were the heavy cavalry squadrons trained for shock effect. Between the phalangial centre and cavalry wings, the tactical hinges of light foot supplied the flexibility for maneuver.

4. World Conquest.—This was the army which Philip led to the conquest of Greece and his son Alexander (*q.v.*) made the instrument of world conquest. The Graeco-Macedonian tactical system met its greatest battlefield test on the field of Arbela, or Gaugamela, in 331 B.C. Darius III, the Persian monarch, had a numerical advantage of perhaps five to one over Alexander's 7,000 cavalry and 40,000 foot. The action took place near the ruins of ancient Nineveh on a plain suited to the Persian cavalry and chariots (*see* fig. 3). Despite the odds against him, Alexander rejected the plan of a night attack urged by his nobles. He opened the battle by seizing the initiative with a rapid advance of his right wing, followed in echelon by the rest of the army. The local superiority in numbers enabled him to drive so deeply between the enemy's left and centre as to reach the rear. A more perfect example of the battle of penetration can scarcely be found in the pages of history, for the Persian host was routed while still possessing a great numerical superiority.

FIG. 3.—BATTLE OF ARBELA, OR GAUGAMELA, (331 B.C.), SHOWING TACTICS OF REAR ATTACK

Alexander's campaigns took him as far as modern India and Afghanistan during the six years after his conquest of Persia. Among his most troublesome foes were the Scythian horsemen who preyed upon his flanks and rear, seeking to cut off detachments. That the nomadic riders of the Asiatic plains could be formidable opponents was demonstrated in later centuries when no less than four Roman armies were lured to their destruction.

The Scythians and Parthians were made natural warriors by a harsh environment. Shunning action at close quarters, resorting to flight when pressed, then returning to the attack in swirling envelopments, they were able to discharge arrows while riding at top speed.

Alexander refused to be drawn into extended pursuits by feigned flights. Noting that the indiscipline of the Scythians made them reckless at times, he trained his light infantry to launch surprise counterattacks and beat the nomads at their own game by cutting off detachments. And once the lightly armed Scythians were attacked at close quarters, they were no match for Alexander's cavalry.

5. The Rise of Rome.—The conqueror's death was followed by the rapid crumbling of the great empire he had founded. But while his former generals disputed for mastery, a young and vigorous war power was rising in the west. Fighting in a simple phalanx of heavy infantry at first, the Romans learned by defeat that the human wall is not suited to battle on rough ground.

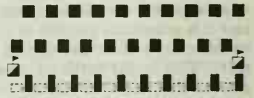

FIG. 4.—LEGION IN BATTLE ORDER: FIRST TWO LINES, HEAVY INFANTRY; THIRD LINE, CAVALRY AND LIGHT INFANTRY ALTERNATED WITH RESERVES

The new tactical system which gradually evolved was the legion (*see* fig. 4). Under the republic it consisted of small and supple infantry units known as maniples, each numbering 120 men in 12 files and 10 ranks. In a typical battle order the first two lines, drawn up in chessboard array, were composed of 10 maniples each. An interval equal to a maniple's front of 60 ft. separated the units, enabling the second line to merge with the first or the first to fall back into the second. The advantages of mobility could thus be exchanged for those of solidarity, since the two lines combined had a depth of ten ranks

and a front of 1,200 ft.

In the third line ten units of light foot were alternated with a like number of reserve units, the former numbering 120 men each and the latter 60. The three lines were 250 ft. apart, and from front to rear one maniple of each classification formed a cohort. This was the Roman equivalent of a battalion, numbering 420 men. Ten cohorts made up the infantry strength of a legion but 20 were customarily combined with a small cavalry force and other supporting units into a self-sustaining little army of about 10,000 men.

The two famous Roman infantry weapons were the *pilum* and *gladius*—the first a 7-ft. javelin used for both throwing and thrusting, and the latter a 20-in. cut-and-thrust sword with a broad, heavy blade. For protection the legionary had a metal helmet, cuirass and convex shield, but aggressive action was deemed a Roman's best defense. The first line attacked on the double, hurling javelins and diving in with swords before the enemy had time to recover. Then came the maniples of the second line, and only a resolute foe could rally from the two successive shocks.

FIG. 5.—BATTLE OF CANNAE (216 B.C.), SHOWING TACTICS OF REAR ATTACK

6. The Battle of Cannae.—When Hannibal descended from the Alps in 218 B.C. with an army of Iberian, Numidian and Gallic mercenaries, the republic paid the penalty of placing too much reliance on heavy infantry and failing to develop a cavalry arm and missile weapons. Two Roman armies, destroyed in the early encounters, were outmaneuvered and cut to pieces by the Carthaginian horse. Finally, Rome incurred a disaster which has made the name of Cannae a symbol ever since of the battle of annihilation and double envelopment (*see* fig. 5).

Hannibal provoked an action, though much outnumbered by a Roman army of 85,000 men. Adopting a convex formation of his foot in the centre, he gradually withdrew it in a feigned retreat until the Roman infantry rushed in recklessly, raising the victory shout. When the converging legionaries were too crowded together to use their weapons, the Carthaginian closed the trap by assailing the flanks and rear of the Roman infantry with his cavalry after driving the inferior enemy horse from the field. The result was a prolonged slaughter of helpless men which lasted until only about 15,000 scattered fugitives survived Rome's greatest disaster.

The victor managed to maintain himself for 16 years in a hostile country before the republic developed in Scipio Africanus a general who understood that a tactical system based on a single arm is as handicapped as a one-armed man would be in personal combat. He carried the war to Carthaginian territory in Spain and finally invaded Carthage. Hannibal returned in the autumn of 203 B.C. to defend his own country but was defeated on the field of Zama (202 B.C.), where the superior Roman cavalry delivered the *coup de grâce*.

7. Tactics of the Cohorts.—The patriotic citizen soldier of the republic's early years was replaced during the century of civil war by a professional soldiery serving for pay and donatives. The cohort of an average field strength of 360 men gradually replaced the maniple as the tactical unit of increasingly larger Roman armies. Ten cohorts made up a legion in the operations of Sulla and Caesar. The 3,600 heavy infantry were supported by enough horse and light infantry to bring the numbers up to 6,000 in all.

The maniple survived only as a unit of a cohort of eight or ten ranks. Four cohorts in the first line and three each in the second and third lines were drawn up in chessboard array, with intervals between units so that one line could merge with another (*see* fig. 6).

Seven legions in three lines, comprising about 25,000 heavy infantry, occupied a mile and a half of front. This was an average of about 11 men to a metre of front as compared to 28 in Alexander's army.

The practical good sense which distinguished Roman tactics was at its best in field fortification. No greater demonstration was ever seen in the ancient world than the 50 mi. of works with which Caesar gained the submission of Vercingetorix and 80,000 Gauls at Alesia. The Romans began by surrounding the strong natural defenses with a system of walls and trenches. When Gallic allies marched to the rescue of his opponent, Caesar surrounded his own army with works of circumvallation and beat off foes both in front and rear. Finally the relieving army disintegrated and Vercingetorix was starved into surrender.

8. Tactics of the Empire.—A gradual change in tactics was evident as Rome evolved from a conquering into a defending power. The spade and axe continued to be effective weapons of a cordon defense established along the frontiers, utilizing such natural barriers as the Rhine and Danube. Where they were lacking, the Romans built such works as the great walls in Britain and the wooden palisades (*Limes*) of Germany.

The cohort, increased to a field strength of 500 to 600 men, remained the unit of tactics which still trusted to the shock of *pilum* and *gladius*. But the 5,000 to 6,000 heavy infantry of the legion were combined with an equal number of supporting troops—cavalry, both heavy and light, and a light infantry made up of archers, slingers and javelin men.

During the first two centuries of the empire the proportion of mounted troops rose from one-seventh to one-fourth as the legion dealt with mounted barbarian raiders. Where war engines had been used chiefly in siegecraft, the empire relied upon them for the defense of fortified border outposts. By the 4th century A.D. according to Vegetius, as many as 10 catapults and 60 *ballistae* were assigned to each legion—a ratio of a "gun" or "howitzer" to 1,000 infantry. This is a higher proportion than the average of three pieces of artillery to 1,000 men in Napoleon's armies.

II. THE CAVALRY CYCLE

1. The Byzantine Horse-Archer.—After the fall of Rome the eastern or Byzantine empire managed to survive by means of bribing the most formidable barbarians and inducing them to move on to the occupation of Italy. The respite enabled Constantinople to develop during the reign of Justinian (A.D. 527–565) a cavalry tactical system which won victories on three continents.

This system was built about the horse-archer. The invention of the stirrup in the 6th century had given an impetus to cavalry warfare, and the historian Procopius has described the tactics of the mounted mercenaries whom Belisarius led to conquests in Persia, North Africa and Italy.

FIG. 6.—LEGION IN BATTLE ORDER: FOUR COHORTS IN THE FIRST LINE AND THREE EACH IN THE SECOND AND THIRD LINES WITH CAVALRY

"But the horsemen of the present time go into battle wearing corselets and fitted out with greaves which extend up to the knee. From the right side hang their arrows, from the other the sword. And there are some who have a spear also attached to them and, at the shoulders, a sort of small shield without a grip, such as to cover the region of the face and neck. They are expert horsemen, and are able without difficulty to direct their bows to either side while riding at full speed, and to shoot an opponent whether in pursuit or flight. They draw the bowstring along by the forehead about opposite the right ear, thereby charging an arrow with such impetus as to kill whoever stands in the way, shield and corselet alike having no power to check its force. Still, there are those who take into consideration none of these things, who reverence and worship the ancient times, and give no credit to modern improvements." (Procopius, *Works*, trans. by H. B. Dewing [Loeb Classical Library], vol. i, p. 7, Harvard University Press, Cambridge, Mass., 1914.)

Belisarius, landing in North Africa with 15,000 men, made easy work of the kingdom founded by the Vandals on the site of ancient Carthage. When he defeated the Ostrogoths in Italy and took Rome, another king was sent as a prisoner to join the captive Vandal monarch at Constantinople. It appeared for a time that Justinian's generals were about to restore the ancient grandeur of Rome, but the conquests were soon lost by an eastern empire ex-

posed to the onslaughts of Slav, Avar, Bulgarian, Persian, Saracen, Frank, Russian and Turk during five centuries of continual warfare.

2. The Byzantine Tactical System.—Byzantine tactics were eminently practical, the spirit of chivalry being unknown in an empire constantly fighting for existence. Greek in speech as well as tradition, Constantinople reduced war to a science with a series of treatises and manuals. The *Tactica* of Emperor Leo the Wise, written about 900, urged that operations should be varied to take advantage of each foe's peculiar weaknesses. Fraud and feigned flights were suggested without apology. If a foe could be bribed more cheaply than defeated, eastern Roman emperors deemed it no disgrace to pay tribute.

Since most of Constantinople's foes were mounted, the tactical system placed the emphasis on heavy cavalry, both archers and lancers. But even though the infantry ranked as a secondary arm, it was well-trained and combined with mounted troops in proportions suited to tactical demands. Squadrons of light horse were employed for scouting and reconnaissance.

Byzantine armies stood between the west and Asiatic invaders at a time when the impoverished Europe of the dark ages would probably have been overrun. Charles Martel and his Franks had difficulty in repulsing a single large-scale Moorish plunder raid on the field of Tours in 732. Yet Constantinople held its own in an 83-year war with the Saracens when Islam was at the height of its conquering momentum.

At the outset the fierce Moslems were cavalry warriors using much the same tactics as the Parthians and Scythians. Where they differed from other plains horsemen was in the ability to learn from their foes. After experience taught the need, the Saracens organized a heavy cavalry of their own and adopted many of the east-Roman tactics. Most astonishing of all, these former desert dwellers took to the sea and built ships large enough to launch two great land and water invasions which were repulsed outside the walls of Constantinople. Only that secret Byzantine weapon known as Greek fire (*q.v.*) saved the imperial city in 673.

3. Tactics of the Franks.—It was fortunate that Europe was spared a severe test, for as late as the 8th century the Franks could raise only masses of untrained and largely unarmoured men using the most primitive tactics. Even after Charlemagne (*q.v.*) introduced strenuous military reforms, he was not able until the final edict of his long reign (771–814) to forbid any man appearing for duty when armed only with a club.

The low esteem in which the Franks were held by skilled warriors is evident from Leo's *Tactica*. Admitting that the headlong charge of mounted Franks with lance and broadsword could be formidable, he advised that "it is best to decline a pitched battle with them until you have put all the chances on your side. You should take advantage of their indiscipline and disorder; whether fighting on foot or on horseback, they charge in dense, unwieldy masses which cannot manoeuvre because they have neither organization nor drill. . . . Hence they fall readily into confusion if suddenly attacked in front and rear—a thing easy to accomplish, since they are utterly careless and neglect the use of pickets and vedettes." (C. M. C. Oman, *A History of the Art of War in the Middle Ages*, vol. ii, p. 204. By permission of Methuen & Co., Ltd., London, 1924.)

Charles the Great made an unceasing effort to create a disciplined army of mailed cavalry out of the Frankish host of unarmoured foot. Ownership of land was the basis of military duty. Proprietors of large estates were commanded to send a mounted warrior equipped with a mail shirt, while masters of smaller tracts must at least combine to arm a man with spear and shield. Thus came into being the feudal system which was to shape the warfare of Europe during the next several centuries.

Despite the emperor's reforms, Europe was helpless for long against the plunder raids of the Vikings. Both the Greeks and Romans had depended on marines trained for shipboard duty and amphibious combat landings, and Constantinople had carried on the tradition. The Norsemen in their turn were unsurpassed as amphibious warriors. Their single-deck ships with carved prows and shield-hung bulwarks were fast and seaworthy, and experience had taught them effective tactics of seizing a beachhead after pushing up such rivers as the Loire and Meuse. The Vikings were formidable fighting men with axe and sword, and their forays grew so bold during the last half of the 9th century that they sacked London and laid siege to Paris.

There was not time to summon large armed forces from a distance against these fleet raiders. Each district had to fend for itself and the feudal system burgeoned as Europeans paid military duty to the local lord upon whom they relied for protection. Cavalry tactics were also given another impetus, for only mailed horsemen could cope with the Norsemen. Seldom has the social progress of an age been so largely shaped by tactical factors.

4. The Decline of Infantry.—In 1066, at the battle of Hastings, the last infantry host of western Europe went down to defeat in England before the descendants of Norsemen who had settled in France and learned to fight on horseback. The mounted and armoured men-at-arms had become virtually the tactical unit of artless battles which had as their first object the seizing of opponents to hold for ransom. Serfs who fought on foot were held in such low esteem that no count was taken of their numbers or losses.

Except for a few crossbowmen, Europe's armies of the crusades had no infantry worthy of the name. A similar situation prevailed in Asia, where the Mongols led by Jenghiz Khan built up a formidable cavalry system.

The bow, lance and scimitar were the weapons of fierce horsemen who used two varieties of bows and three "calibres" of arrows for various tactical purposes.

The Great Wall of China, with its 1,500 mi. of earth-filled brick or granite, proved to be no serious obstacle to invaders who swept like a pestilence from the Yangtze to the Vistula during the 13th century without incurring a single major defeat. Whether the conquerors could have continued to win victories in the mountains and forests of western Europe is open to speculation, for they returned to Asia after defeating the feudal horsemen of Hungary and Poland.

5. Medieval Tactics of Europe.—In contrast to the supremacy of the offensive in Asia, the defensive was all-powerful in medieval Europe. Concentric fortification added to the difficulties of besiegers by making it necessary to attack walls within walls as well as outer wards and foreworks, while the crossbow provided the garrison with a means of enfilade fire from rounded keeps.

Meanwhile, the gradual transition from chain to plate armour made the mailed knight and his barded charger more invulnerable to the weapons of the day (*see* ARMOUR, BODY).

The wretched communications of medieval Europe were a deterrent to maneuver even if the unruly armed forces of the 13th century had been disciplined enough to attempt it. It was seldom possible to force a battle on an unwilling opponent, and methods of supply were so primitive that an army often had to abandon a half-finished campaign after eating a province bare.

That the tactical superiority of the knight owed a great deal to his monopoly of the prerogative of bearing arms was demonstrated by despised Flemish burghers at the battle of Courtrai in 1302. French men-at-arms, putting down a revolt, launched their usual thundering charge only to bog down in disorder upon reaching marshy ground they had not troubled to reconnoitre. The Flemish foot clubbed the knights out of the saddle and dispatched them as they lay helpless in the mud, too burdened with armour to defend themselves. This was a disagreeable ending for a medieval battle as compared to being held for ransom.

6. Longbow and Halberd.—The use of gunpowder in the 13th century made it inevitable that the supremacy of the man of iron in his house of stone could not be long maintained. But the first handguns were not as effective as either the crossbow or English longbow, and it was actually the rise of disciplined forces of yeomen using infantry tactics which restored the balance between the offensive and defensive in medieval Europe.

Although a few weapons using gunpowder were present on the field of Crécy (*q.v.*) in 1346, the outcome owed more to the discipline and tactics of an English army in which every man re-

ceived a fixed and regular wage. For it was truly a national army that Edward III led to France, and the French knights would probably have been defeated even if the invaders had been armed with a less effective weapon than the 6-ft. longbow. Its superiority over the crossbow of the Genoese mercenaries was proved in a preliminary exchange of missiles. Edward had placed his dismounted men-at-arms in the centre as spearmen, and on both projecting wings the lightly armoured archers stood behind ditches and pointed stakes. They poured deadly flights of arrows into the front and flanks of the advancing French knights until 16 successive charges had been repulsed with heavy losses.

Another infantry tactical system was winning victories meanwhile in central Europe at the expense of the Austrian knights. Swiss burghers and peasants, fighting for their liberties, depended on a medieval phalanx composed of spearmen and warriors armed with the halberd—an 8-ft. shaft which had the blade of an axe, the point of a spear and a hook for pulling a rider out of the saddle.

The Swiss phalanx of the 15th century consisted of three-fifths halberds, one-fifth spears and one-fifth missile weapons, chiefly crossbows with handguns slowly gaining in favour. In the interests of mobility the men of the cantons discarded all armour except the helmet and cuirass. Marching 30 mi. a day to meet the enemy, they attacked with a celerity and discipline which were disconcerting to medieval adversaries. If hard-pressed, the Swiss "formed the hedgehog" by facing outward in all directions as men from the rear ranks filled any gap in front.

7. Early Victories of Gunpowder.—After beating mailed horsemen who had resisted tactical change, the English and Swiss in their turn were defeated because they lagged behind the military progress of the age. It had taken weapons of gunpowder a century and a half to have much influence on tactics, but at the siege of Orléans in 1428–1429 both sides used cannon firing stone balls. The French guns were better served than the mortars and bombards brought by the English, who met defeat at the battle of Patay after abandoning the siege.

Charles VII of France raised the first standing army of the middle ages—9,000 permanent troops, paid and armed by the king. This force gradually won back the French territory conquered by the English in the Hundred Years' War, and at the battle of Formigny in 1450 the invaders were decisively beaten after making their customary defensive stand with the longbowmen on both wings.

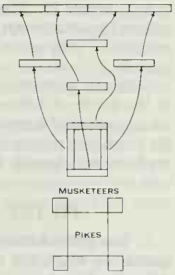

FIG. 7.—EVOLUTION OF THE SQUARE INTO THE LINE

Instead of launching their usual charge, the outnumbered French brought up culverins, or medieval fieldpieces, and cut the English archers to pieces with enfilade fire.

The Swiss phalanx was granted a longer period of grace, but eventually it too was to pay with defeat for clinging obstinately to outworn tactics.

Of all the early exponents of gunpowder weapons, perhaps the most remarkable was John Žižka's army of Bohemian peasants. Several crusades were proclaimed by Pope Martin V against these dissenting followers of John Huss, but the German and Hungarian knights encountered the most advanced tactical system of the new age of gunpowder. Combining the strategic offensive with the tactical defensive, the Hussite military genius drew up a line of "wagonforts"—armoured wagons affording cover to infantry armed with both handguns and crossbows. Between the vehicles were cannon mounted on four-wheeled carts and protected by infantry with pikes. Behind both wings the cavalry waited in readiness to deliver a counterstroke or lead a pursuit.

The combination of the three arms continued to prevail without a single reverse after the death of the blind leader. More than 50 battles and combats were won by the Hussites in 14 years, but civil war led to the destruction of armies which had been invincible against the invading knights.

III. THE MILITARY RENAISSANCE

1. The Fall of Constantinople.—In 1453 it was evident that a new military age had dawned when the Turks breached the walls of Constantinople with a siege train of 70 cannon. After 40 days of bombardment enough towers had been leveled and holes opened in the masonry for a general land and sea assault to succeed.

If weapons of gunpowder could batter down the strongest walls of Europe, it was plain that a defensive based on iron men in stone castles was no longer dominant. By the middle of the 15th century the plate armour panoply had become so heavy that special breeds of horses, the ancestors of Percherons and Belgians, were reared as chargers. Only armour of prohibitive weight could stop a ball from a handgun at close range, and men were beginning to suspect that mobility offered more protection than iron.

Fortification (*q.v.*) and siegecraft had changed but little in 2,000 years. Down to the 14th century an Assyrian of 700 B.C. would not have found much to astonish him in the attack and defense of walled strongholds in Europe. But after the fall of Constantinople it was realized that the wall was obsolescent. Works of the future must be low and screened, burrowing into the earth for security. Besiegers must dig their way forward in a maze of parallels and approaches affording shelter from the fire of the besieged.

About this time the ponderous handgun was being superseded by the arquebus—a comparatively portable matchlock which could be fired from the shoulder. Improvements in the manufacture of wheeled cannon had resulted in slender guns of cast iron or bronze firing iron balls. The principle of the limber had been discovered thus increasing mobility, and the invention of the trunnion permitted the muzzle to be elevated or depressed for more accurate aim. (*See* ARTILLERY; SMALL ARMS, MILITARY.)

The new weapons were utilized by brilliant captains in the struggle between France and Spain for control of Italy early in the 16th century. Tactical values changed from one battle to another with bewildering rapidity. On the field of Cerignola in 1503 the French infantry and Swiss mercenary pikemen were mowed down by the fire of Spanish arquebusiers who counterattacked and captured the enemy's entire artillery train. Nine years later, at the battle of Ravenna, the Spaniards again put their trust in entrenched arquebusiers. But this time the French moved 24 cannon to the enemy's flank and surprised the Spanish infantry with a deadly enfilade fire which decided one of the bloodiest battles of the age.

Again in 1515 the French artillery upheld its reputation by putting an end to the Swiss legend of invincibility. After winning their independence the men of the cantons had become the competitors of the German *landsknechts* as Europe's leading mercenaries. And though the Swiss had increased the proportion of firearms in their phalanx, they still depended mainly on the "push of pike" for victory. In the battle of Marignano, as Spanish hirelings, they paid the penalty of obsolescent tactics when the French repulsed 30 charges by blasting holes in the Swiss ranks with cannon and launching cavalry counterattacks.

Ten years later, on the field of Pavia, the French artillery seemed on the way to another triumph. At the critical moment, however, the victory was won by a surprise advance of 1,500 Spanish arquebusiers. Taking cover behind walls and hedges to fire at will, these elusive marksmen cut down *landsknechts* who had no opportunity to use their pikes.

2. Pike and Arquebus.—Not only had the Spaniards won Italy; they had also founded a new school of infantry tactics which was to rule the battlefields of Europe for a century and make incredibly daring conquests in the new world. Although the battle of Pavia had been won as much by mobility as firepower, the agile combat groups of that victory were gradually replaced by the first phalanx of the age of gunpowder—solid columns of infantry known as battles. Various combinations of "shot and pike" were used, but usually the arquebusiers were drawn up on the corners of battles 25 ranks deep. After firing at the word of command, each rank withdrew to the rear to reload and gradually moved forward by successive volleys until its turn came again. It was the function of the pikes to protect the arquebusiers while reloading.

When the enemy's ranks were broken by firepower, the pikemen evolved from square into line and advanced, shoulder to shoulder, in a massive charge calculated to sweep the field (*see* fig. 7).

The *tercio* of about 3,000 foot was the basic Spanish tactical unit. Consisting of 12 companies of about 250 men each, the fighting strength in 1534 was divided equally between pikemen and arquebusiers. Cavalry was represented in one-twelfth of infantry strength, and artillery by an average of one gun to each 1,000 foot.

The value of tactics and discipline was illustrated during the reign of the emperor Charles V (*q.v.*) when small bands of Spaniards won amazing victories over barbarian hordes in Mexico, Peru and the islands of the Caribbean. The natives were not wanting in sacrificial courage, and their advantage in numbers compensated for inferiority in weapons. One Aztec might have been a match for a Spaniard in single combat, but a thousand Aztecs were routed by a hundred Spaniards because they lacked the tenacity instilled by discipline as well as tactical system and precision.

3. Maurice of Nassau.—Tactical history repeated itself when the Dutch fighting for independence organized the first cohorts of the age of gunpowder to oppose the first phalanx. The Spanish forces had won the early battles of the Netherlands revolt with ease over larger armies of Dutch students, rustics and burghers. Defeat taught the harsh lesson that patriotism was not enough, and Maurice of Nassau (*q.v.*) trained a dependable Dutch standing army. Since the Spanish battles were unwieldy in maneuver, he revived Roman mobility by forming infantry regiments of 800 to 1,000 men, consisting of ten companies of pikemen and musketeers in equal numbers.

During the Wars of Religion the arquebus had been replaced by the musket, which was simply a heavier and more effective matchlock. Accuracy was increased by the introduction of a portable iron fork serving as a rest when the soldier took aim, though it was still necessary to protect him with pikes while reloading.

Another 16th-century invention, the wheel-lock pistol, dated a revival of cavalry tactics. Fired by a steel-toothed wheel which struck sparks from pyrites after the release of a tightly wound spring, the new pistol led to the cavalry tactic known as the caracole, designed to harass squares of pikemen. Advancing in successive waves, the horsemen fired their wheel locks in the faces of the enemy, then swerved off to the rear to reload.

The war in the Netherlands was decided chiefly by siegecraft and fortification. But at Nieuport in 1600 the mobile Dutch cohorts defeated the Spanish phalanx in a battle fought among seaside dunes. Maurice's companies, drawn up in chessboard array, had a great advantage in maneuver over the three Spanish battles of about 3,000 men each. The Dutch prince used heavy artillery to open the action and brought up fieldpieces to accompany his infantry and give close support. When the Spanish squares broke, Maurice's small but well-trained cavalry led the pursuit.

4. Gustavus Adolphus and the Thirty Years' War.—It remained for Gustavus Adolphus (*q.v.*) to improve upon Dutch reforms and merit the title, "father of modern tactics." The Swedish king organized his infantry into brigades, each consisting of two regiments which in turn included two battalions. Each battalion of 1,000 men was divided into eight companies of an average strength of 75 muskets and 60 pikes.

Swedish armourers had developed a lighter musket and Gustavus is credited with being first to introduce paper cartridges to speed reloading. On the firing line his six ranks advanced in open order and closed up into three, the first rank kneeling and the other two standing while firing a volley.

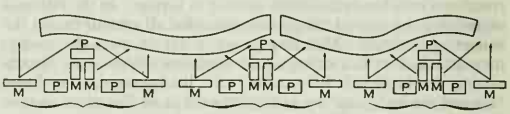
The Swedish artillery also benefited from innovations. Advances in metallurgy having made possible a lighter fieldpiece, Gustavus recalled most of his old ordnance. It was recast into four-pounders of 3 ft. 10 in. in length, 400 lb. in weight and 2:6 in. calibre. Four men or a single horse could handle the new gun on the field, though the four-pounders of other armies weighed half a ton or more.

The first artillery cartridge was developed as ammunition—a thin wooden case holding a prepared powder charge wired to the ball. Improvements were also made in the "bomb" or shell—a hollow iron sphere filled with gunpowder and fired with a lighted fuse. Reloading was speeded to such an extent that the Swedish four-pounder could be discharged eight times while the best musketeers fired six volleys. This was the first regimental piece of history, and each Swedish regiment of 1,000 men brought two four-pounders into the field.

It was characteristic of the forthright Swedish king to replace caracole tactics by training his cavalry entirely for shock effect with pistol and sabre. As light cavalry he organized Europe's first regular dragoon corps—a tactical hybrid made up of men armed with carbine and sabre who could fight either in the saddle or on foot.

The decline in body armour was accelerated when Gustavus himself discarded all protection save a leather buff coat. Field fortification was also reduced to its simplest elements by an army priding itself on the boast, "The Swedes do not defend their men with walls; the Swedes defend their walls with men."

In the battle of Breitenfeld (1631), the first large-scale test, Gustavus opened the action by committing 100 cannon to a long-distance artillery "preparation." Then his self-sustained battalions, each a mobile combat group of pikemen and musketeers



FROM CAPT. HART, "GREAT CAPTAINS UNVEILED" (BLACKWOOD)

FIG. 8.—COMPANIES OF MUSKETEERS AND PIKEMEN DRAWN UP IN COMBAT FORMATION BY GUSTAVUS ADOLPHUS

with their own four-pounder, were able by virtue of rapid shifts to concentrate fire where it was most effective (*see* fig. 8). Of the 33,000 imperial troops, 7,000 were captured and 12,000 killed or wounded. Only about 2,000 survivors could be rallied after the pursuit.

Although Gustavus inflicted another defeat on the imperialists in the battle of Lützen the following year, he paid with his life. In two years of campaigning he had overrun Germany, but after his death the army soon degenerated into another of the plundering hosts which made the war one of the most destructive of history.

IV. THE AGE OF LINEAR TACTICS

1. The New Age of Moderation.—It has aptly been said that the tactics which end one war are those which will begin the next. After the bloody battles of the Thirty Years' War resulted in a prolonged stalemate, the vicomte de Turenne (*q.v.*), commanding mercenaries paid by France, cleared the enemy from Bavaria in a campaign of maneuver, compelling the king to sue for an armistice. Avoiding battle unless he had an overwhelming advantage, the French tactician relied upon caution, precision and surprise to drive the enemy into ravaged areas while retaining his own sources of supply.

Thus the savage excesses of the war were made to appear futile by tactics which foreshadowed the most moderate era of strife in modern history. The founding father of the new military age was the marquis de Louvois, minister of war at the court of Louis XIV of France. Recognizing that tactics are dependent on supply, he organized a quartermaster general's department and a trained commissariat. As fixed points of maneuver, he established magazines at strategic centres for storage of reserves of food, ammunition and equipment.

The French minister also foresaw that two recent improvements in weapons would lead to tactical change. The first was the socket bayonet, which superseded the pike by providing every musketeer with his own means of protection. Equally important was the invention of the flintlock musket, making it possible to dispense with the clumsy lengths of smoldering "match."

Even Gustavus had not been able to reduce the depth of his formations to fewer than six ranks. But now that it was no longer

necessary to combine pikes with muskets, Louvois perceived that the day of linear warfare had dawned. His famous drillmaster, Gen. Jean Martinet, whose name has lived as a byword, trained the troops of the new French armies to deploy from column into line and advance in three ranks, pausing to fire platoon volleys at the word of command. The effect depended on precision of approach, and the men were trained to move forward in unison, keeping step at a stately cadence of 80 paces a minute.

Although the volunteer system prevailed in theory, the soldiers of the new military era were actually recruited for the most part by force, fraud or various forms of legalized blackmail. Since it took from three to five years to train a man for linear tactics, Louvois made a study of morale with a view to reducing the high ratio of desertions prevailing in the Thirty Years' War. The French army became the first to be completely uniformed, and the war minister was a pioneer in the awarding of medals for valour. He set another tradition with his annual war games in which large bodies of troops were trained to maneuver under simulated combat conditions.

2. The Wars of Louis XIV.—The French army had no equal in numbers as well as quality when Louis XIV began the aggressions which were to involve him in wars throughout his long reign. But the battle of Seneffe in 1674 made it plain that grievous losses were to be expected by the best troops when opposing lines traded volleys at 50 paces as a prelude to charging with the bayonet. Only iron discipline could fit men to stand firm and fill the gaps in the ranks, for the death casualties alone in this clash amounted to 17% for both armies.

Large-scale actions depended virtually on mutual consent, since a general could refuse by withdrawing to country too hilly or wooded for the precision demanded by linear tactics. As all armies adopted the magazine system, fortification and siegecraft became more decisive than battle, and some thrifty victories were won by Sébastien le Prestre de Vauban (*q.v.*) in attacks on enemy strongholds. He prevailed on Louvois to increase the number of mortars and organize battalions of troops armed with grenades. It became the military fashion to select only the tallest men for this dangerous duty, so that the grenadiers were recognized as the elite of the infantry.

3. The Tactical Theories of Marshal Saxe.—As compensation for the heavy battle losses, pillage and devastation were reduced to a minimum by disciplined armies of long-term troops. Payment was made for supplies even in enemy territory, and generals sought to gain their ends by maneuver rather than hard fighting.

"I am not in favor of giving battle," declared Marshal Saxe (*q.v.*), who won a memorable victory over a French and Dutch army at Fontenoy in 1745. "I am even convinced that a general can wage war all his life without being compelled to do so."

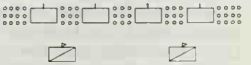


FIG. 9.—MARSHAL SAXE'S COMBINATION OF INFANTRY, LIGHT INFANTRY AND CAVALRY

Saxe foresaw the need for a trained light infantry and managed to raise companies for his Netherlands campaigns in the War of the Austrian Succession (*q.v.*). His victory at Fontenoy was made possible by redoubts from which his troops poured a deadly enfilade fire into their assailants. He also experimented with the unit which became the tactical ancestor of the division (*see* fig. 9). Two brigades of infantry and one of cavalry were combined with artillery into a unit intended to be tactically self-sufficient in local operations, yet capable of concentrating with like units for battle.

4. Frederick the Great.—Saxe's theories might have found widespread adoption sooner if they had not been eclipsed by the dramatic victories of Frederick the Great (*q.v.*). On the field of Leuthen in 1757, he won one of history's most famous victories by defeating an Austrian army of 72,000 troops with 43,000 Prussians. As a tactical innovation, Frederick brought up a battery of ten fortress guns to support his infantry battalions, each of which dragged a six-pounder to supplement the heaviest concentration of artillery ever seen on a European battlefield up to that time. The blue-clad Prussian infantry advanced in staggered alignment, so that the left was refused while the heavily reinforced right bore down on Austrians outnumbered at the point of contact. This was the "oblique order" which won fame for Frederick, though it was nothing more mysterious than a well-timed and executed flank attack which collected a victory already half-won by the fortress guns and six-pounders (*see* fig. 10).

Frederick's greatest contributions to tactics, in fact, were in artillery. Regimental pieces had previously been drawn into battle by soldiers tugging at ropes, but Frederick blamed his crushing defeat in the battle of Kunersdorf on lack of artillery mobility. As a remedy, he ordered that four horses in file be hitched to each piece, making it possible to bring larger quantities of ammunition into the field. He also placed more emphasis on howitzer fire in battle than predecessors who had regarded this type of cannon as being merely a weapon of siegecraft.

V. NAPOLEON AND 19TH-CENTURY TACTICS

1. The American Revolution.—Many of the tactics of the Napoleonic era had their roots in the American Revolution (*q.v.*). La Fayette and two of Napoleon's future marshals, Jean Baptiste Jourdan and Louis Alexandre Berthier, returned from service in that war with glowing accounts of new light infantry tactics. On the British side, Sir John Moore (*q.v.*), who was to shape the tactics of Wellington's armies, participated as a youthful subaltern. It was evident to these observers that the American frontier rifle ranked as history's first infantry firearm of precision. Although it took twice as long as a smoothbore musket to reload, it had from two to three times the effective range in addition to an accuracy which was beyond comparison.

Although a majority of the Americans carried smoothbore muskets, the farmers and villagers of the new world were accustomed to hunting small game at a time when laws against poaching and possessing firearms prevailed in Europe. The greenest American recruits took aim instinctively while European regulars were trained to point the piece in the general direction of the foe and fire at the word of command. Thus at the battle of Bunker Hill (*q.v.*) most of the British shots droned harmlessly over the heads of Americans who inflicted casualties of 45% with their limited ammunition by taking "aim at the handsome waistcoats."

Because of the broken country, light infantry tactics flourished in the American Revolution. And since all the armies were small, a two-rank line gained approval as a means of adding to infantry firepower.

2. French Revolutionary Tactics.—The "horde tactics" of the French Revolutionary armies evolved from military poverty. Lacking magazines, the sans-culottes gained in mobility by becoming less dependent on bases and lines of communication. Lacking tents, they learned to bivouac in the field, where all units could be more swiftly concentrated. Lacking supply wagons, they learned to march at a more rapid cadence than their opponents. Lacking training for the precision of linear tactics, they gradually developed a more effective attack of their own.

La Fayette had urged that a rifle company be included in each battalion of the revolutionary forces, and Jourdan tried to instruct his troops in light infantry tactics. Not much came of these efforts, but at least two lessons of the American conflict were put into effect—fire at will, as distinguished from volley fire, and taking natural cover on the skirmish line. Upon coming in contact with the enemy, the bolder spirits of a revolutionary army swarmed out to fire from ditches or behind hedges. The platoon volleys of linear tactics were not effective against these elusive French skirmishers, who took to their heels when threatened with a bayonet charge. Fighting of this sort was so interesting and com-

paratively safe that more and more men participated. Finally, at the battle of Hondschoote in 1793, General Jourdan's forces concentrated swiftly and almost literally mobbed an allied rear guard detachment with a wild bayonet attack.

Fortunately for the sans-culottes, the royal artillery and engineers, as technical branches, had never attracted the nobility. Many of the officers adopted the cause of the Revolution, and by 1793 the French were able to open a battle with a respectable cannonading while the skirmishers were peppering the enemy with harassing fire. Skill and confidence came with experience until the Revolutionary masses of attack bore more resemblance to columns and less to rioting mobs. The allies found it disconcerting, moreover, when a French army doubled in size within a few hours as distant units hastened to the battlefield at the quick-step from all sides.

3. Bonaparte's Early Victories.—It is taking no credit away from Bonaparte's genius for war to point out that he adapted rather than originated his tactics. He was the heir not only of French Revolutionary tactics but also of an army of battle-hardened veterans who had won some notable victories over the allies. From the old royal army he inherited the system of dispersion and concentration of divisions and brigades, as developed by Saxe and Marshal de Broglie. And on the eve of the Revolution, Jean Baptiste de Gribeauval's artillery reforms had reduced the weight and increased the mobility of regimental guns.

Bonaparte was not a great battlefield tactician. He was at his best in that hybrid between tactics and strategy known as "grand tactics"—the assembling of units prior to battle for a last-minute concentration by forced marches on the battlefield itself. No longer could an adversary refuse combat, as in the days of linear tactics. Bonaparte forced such an opponent to fight by sending a column around to threaten his line of communications. When the enemy was brought to bay, Bonaparte could summon his own outlying columns as mobile reserves in less time than could the armies trained for linear tactics.

The preliminary swarms of skirmishers, the cannonading by regimental guns firing grapeshot at close ranges, the battlefield concentration and the attack by bayonet columns of infantry—these were the four stages of Bonaparte's early victories. Some of them were gained by envelopment, some by penetration and others by plain frontal assault, according to the dictates of a marvellous intuition.

4. Tactics of the Empire.—Every conqueror runs the risk of teaching the art of war to his opponents, and Napoleon, as emperor, found his own tactics being used against him with increasing skill. In the battle of Eylau (1807) 7,000 Russian reinforcements appeared at the critical moment after the delay of the French concentration by a snowstorm. Napoleon barely escaped defeat at an appalling cost in killed and wounded.

Two years later, in the battles of Aspern-Essling and Wagram, the archduke Charles (*q.v.*) and his Austrian army gave Napoleon some anxious moments. France was weary of war, and as the quality of infantry conscripts declined, the emperor placed more reliance on bulk. He used artillery in great masses, and on the field of Wagram he sent an enormous hollow square of 30,000 men to advance on the Austrian centre behind 104 guns. This was the decisive blow, but the victory had been won at a price of 23,000 French killed and wounded.

5. Wellington's Tactics.—At a time when other generals were imitating Napoleon's methods, the duke of Wellington defeated French columns with linear tactics and depended on seaborne supplies while outmaneuvering an enemy living on a country eaten bare. He too was an adapter rather than an originator, for the British tactical system was largely the creation of Sir John Moore. In 1803, training troops to meet an expected Napoleonic invasion, he reduced the standard three ranks to the two-rank line of the American Revolution. He applied another American lesson by organizing three regiments of riflemen for his light division, soon to win fame as the most celebrated unit of British battles in Spain.

Moore was killed in his first Peninsular operation, but Wellington applied his tactics so successfully as to become one of history's few unbeaten generals. The French, as Europe's masters, felt obliged to attack. Their opponent profited by being able in every major battle to choose his own ground and draw up his "thin red line" behind a low ridge. This gave him the double advantage of protecting his men from ricocheting cannon balls and compelling the French bayonet columns to advance uphill. A screen of skirmishers from the light division was deployed along the forward slope. Since their rifles outranged French muskets, they were able to harass the enemy columns with aimed fire while the British artillery thinned them with shrapnel. The two-rank line gave the redcoats a wider front for musketry, and Wellington met the main French shock with steady platoon volleys. If the enemy wavered, he ordered a British bayonet counterattack.

This was the tactical formula, repeated with few variations, which won victories over Napoleon's marshals for five years in Spain. Wellington proved to be a match for the French in swift concentrations, and on one occasion his light division completed a march of 43 mi. in 22 hours. But it was with infantry firepower that he beat opponents who trusted too much in the bayonet, for Napoleon had refused to adopt the rifle and neglected musketry training in spite of his assertion, "The power of infantry lies in its fire." (*See* also PENINSULAR WAR.)

6. Half a Century of Transition.—At Waterloo, Wellington needed only the tactics that had won for him in Spain. But an era came to an end on that June day in 1815, when infantry, cavalry and artillery were in close contact and could be controlled by the general as easily as a regiment a century later. All this was changed by the widespread adoption of the percussion cap and long bullet, which multiplied the range as well as accuracy of the rifle and made it a universal military weapon. No longer was it possible to place the guns in front of the infantry, as was done sometimes during the Napoleonic era, with the cavalry close behind. No longer was it possible to mass cannon only 500 yd. from the enemy, as at Borodino, and blast a bloody path to victory. Thus the old battle order, which had changed but little in essentials since the day of Gustavus Adolphus, was relegated to the past. To command an army as Wellington did at Waterloo was out of the question; to render its separate parts co-operative demanded staff work and not merely a powerful voice.

During the half century preceding the American Civil War, inventions came so rapidly that soldiers could not keep pace. The revolver and repeating carbine opened up new vistas for the cavalry and rendered obsolescent the charge of lancers. Rifled and breech-loading fieldpieces worked a revolution in artillery tactics, just as the telegraph, the railroad and the steamship made it necessary to revise all previous ideas of military transport and communication.

Few precedents were available when green armies of citizen-soldiers met in the opening engagements of the American conflict. But if they had more to learn, they had less to forget than the tradition-ridden soldiers of Europe. And before the four-year struggle ended, the Americans had put into effect many of the tactics that would shape the outcome of World War I.

7. The American Civil War.—Four million men bore arms in the American conflict. More than 2,000 combats took place, of which 149 were of enough importance to be called battles. Yet these far-flung operations were dominated throughout by the defensive power of the rifle, supported by the axe and the spade.

The railway gun, the land mine, the wire entanglement, the observation balloon, the hand grenade, the field telegraph—these were some of the innovations or revivals of the Civil War. But they played second fiddle to the demonstrated ability of the man in the rifle pits to hold his own against three attackers. Since most of the operations occurred in wooded country, soldiers of both sides learned to cut "head logs" with firing slits to give added protection along the parapets of trenches. Generals were taught by experience that marksmen in log-faced earthworks, supported by rifled artillery, could seldom be dislodged except at a ruinous cost in casualties. Lee at Malvern Hill and Gettysburg, Grant at Vicksburg and Cold Harbor—the best tacticians of the war met with bloody repulses when they underestimated the firepower of opposing riflemen.

On the other hand, paradoxical as it may seem, the defensive power of the entrenched rifleman enabled Lee to launch successful

attacks on opponents with a material advantage. Relying on the proved ability of one rifleman to stand off three adversaries, the Confederate general dared repeatedly to divide his army in the face of a more numerous enemy. At Second Manassas, for instance, Jackson "contained" more than double his own strength in a holding battle until Lee could arrive the next day and deliver the decisive counterstroke. It was Lee's turn at Chancellorsville to fight a defensive battle with half his army while Jackson led the other half around the Union right in a surprise flank attack, thus winning one of history's few authentic victories over two-to-one numerical odds.

Grant became the first general to command the army of a million men. But European soldiers professed to see in the Civil War only the incoherent clashes of armed mobs, and in 1870 the French and Prussians made it evident that they had learned nothing from the American precepts. They sent cavalry in suicidal charges against infantry armed with breech-loading rifles with an effective range of 1,000 yd.; they took needless losses from rifled artillery as the penalty of close formations; and they persisted in infantry frontal attacks despite the fact that neither side succeeded in taking a single position by such tactics.

VI. WORLD WAR I

1. The Battle of the Marne.—It was the tragedy of World War I that the century of comparative European peace since Waterloo seemed to have made romanticists out of the professional soldiers who held in their hands the lives of millions of conscripted citizens. Despite the lessons of the American conflict, confirmed by the machine guns of the Russo-Japanese War, France's generals of 1914 had a mystical faith in the *offensive à outrance*—the headlong offensive, compounded of mass, velocity and morale. They believed that the prewar scale of two machine guns to a battalion was adequate; and as late as 1915 the British commander, Sir Douglas Haig, asserted that it was "a much overrated weapon" and agreed that the French scale was "more than sufficient." (B. H. Liddell Hart, *A History of the World War, 1914–1918* [enlarged ed. of *The Real War, 1914–1918*], p. 143, Little, Brown & Co., Boston, 1935.) By that time, nearly a million men had been killed by machine guns on the western front.

The German generals were more realistic, but they too had complete faith in the offensive and regarded any reference to defensive advantages as bordering on defeatism. Both the French and German tacticians considered a defensive action excusable only when "each man will die in place rather than give ground."

The Germans, who were better prepared at the outset, seemed to be proving their case as they swept through Belgium and northern France. The French soldiers, uniformed in red breeches for the sake of morale, endured frightful losses. And since the German generals held that "the abandonment of close-rank formations is an evil which should be avoided whenever possible," their troops in turn provided the French artillery with lucrative targets.

In the battle of the Marne the French stopped the invaders by taking advantage of blundering last-minute revisions in the German envelopment plan. Then began the "race to the sea" which was to result in a continuous front of trenches from the Atlantic to the Alps. The German losses of the first four months were 747,465 killed and wounded; the French had 854,000 casualties during the same period.

2. Deadlock on the Western Front.—In the spring of 1915 the entente nations believed that artillery was the key to the deadlock. But even after a prolonged bombardment by 1,140 pieces of heavy artillery, 53 French infantry divisions were able to advance only 3,000 yd. on a 12-mi. front. The enemy simply weathered the storm of steel in deep dugouts until the barrage lifted, then manned the machine guns which cut down attackers plodding across no-man's land under heavy burdens of equipment.

The Germans risked the censure of neutral nations in an attempt to win a decision with poison gas in the Neuve Chapelle sector. But the Canadians held out until they could be reinforced, and millions of soldiers were soon wearing gas masks as all armies resorted to chemical warfare. Steel helmets also became generally adopted as protection against shell fragments.

The entente nations made a bid for victory in 1915 by launching a land-and-sea assault on the Dardanelles for the purpose of knocking Turkey out of the war and battering down "the unlocked back door" of the central powers. A costly failure, after an eight-month campaign, was blamed on the supposed impossibility of conducting a major amphibious operation against modern weapons. Actually, as time was to prove, British and French repulses on the Gallipoli peninsula resulted from violations of basic tactical principles. (*See* DARDANELLES CAMPAIGN.)

By 1916 both sides recognized the dependence of ground operations on air warfare (*q.v.*). The two great campaigns of the year were the German offensive at Verdun and the Franco-British offensive on the Somme. New infantry tactics were introduced by the Germans as specially trained combat groups, armed with flame throwers, advanced after a terrific bombardment. Verdun became known as "the sausage grinder" as the struggle continued for ten months with losses to the French of 442,000 men and to the Germans of 278,000. Although it cannot be said that either side won the battle of attrition, the French heavy artillery and chain of underground forts stopped the enemy. At Verdun, moreover, sweeping changes in tactics were indicated when the French demonstrated that an army could be supplied by motor transport.

The Franco-British offensive on the Somme turned into another heroic slaughter. German defenses in depth, extending as far back as 10 mi., frustrated every attempt at a worthwhile penetration, and "gains" of a few hundred yards were recorded in London headlines. The British made a premature and unsuccessful use of tanks, but lack of planning and preparation actually served to retard the progress of armoured warfare.

3. The Offensives of 1917.—The western front was not the only theatre of war, but it was recognized that France would be the area of ultimate decision. Entente generals still trusted in the spring of 1917 that by increasing the density of artillery the infantry could make headway behind a rolling barrage timed to the advance. But even a ratio of a gun to 6 yd. of front was not enough, and the German machine guns continued to reap their deadly harvest.

It had been necessary for a civilian, David Lloyd George, to provide the British army with a realistic scale of machine guns and trench mortars in spite of the reluctance of General Haig and Lord Kitchener. Another civilian spoke for the dead of France when Premier Georges Clemenceau remarked that "modern war is too serious a business to entrust to soldiers."

Although Belgian engineers had warned against destroying the drainage system of reclaimed lands, 103,000 tons of shells were fired in the preliminary British bombardments of the third battle of Ypres, known to the soldiers as Passchendaele. Mustard gas was added to the horrors of the 100-day battle as both armies wallowed in the swamp created by 4,300,000 British shells. Haig's gains were negligible despite 300,000 casualties, and the Germans considered Passchendaele "the supreme martyrdom."

From the entente viewpoint, one of the few consolations of a gloomy year was the British breakthrough at Cambrai on a 6-mi. front with 381 tanks supported by infantry. Attacking by complete surprise, after a last-minute hurricane barrage, the clanking cavalcade ripped through defenses in depth and took 7,500 prisoners and 120 guns at a low cost in casualties. Adequate infantry forces had not been provided by high-level British generals who envisioned a cavalry exploitation, and the territorial gains of Cambrai were lost to a German counterattack. Even so, the operation had demonstrated that armour was the key to a decision on the western front. (*See* also CAMBRAI, BATTLE OF.)

The Germans had meanwhile developed a key of their own in a new concept of offensive tactics known as "infiltration." It called for the rapid advance of dispersed "storm groups," armed with automatic rifles and light mortars, preceding the main body of infantry. These specialists were to probe for weakness and break through wherever they could find an opening. Their mission was to surprise enemy machine guns and artillery from the flanks and rear while leaving the strong points to be enveloped frontally by following waves of infantry, closely supported by artillery and tactical aircraft. These new tactics of infiltration, carried

out by secretly trained troops, promised to create enough demoralization for a penetration as far back as corps command posts and communication centres.

Leaders of both sides realized early in 1918 that it was destined to be the year of decision. All the nations which had participated from the beginning were war-rotted except Great Britain and Germany, and it was a question whether the newly trained U.S. divisions could cross the Atlantic in time to compensate for the defection of Russia, convulsed by revolution.

4. The Mobile Warfare of 1918.—Infiltration won the first round. The German spring offensive in Picardy resulted in gains for a few days such as the western front had not known since 1914. Within a week a salient had been extended to a maximum depth of 40 mi. in the British sector by German columns which threatened to drive to the sea. Then, suddenly, the attack ground to a halt and the front was stabilized once more.

This loss of momentum was no coincidence. What had happened was that the Germans had outrun their supplies, for the rail transportation and horse-drawn artillery of 1918 were not adequate to nourish a rapid advance. General Ludendorff made four bids for a decision and each time the early gains merely resulted in creating another salient and two more German flanks.

The last effort, on July 15, 1918, was a complete failure. Attacking on the Champagne front, the Germans were trapped in the French elastic defenses planned by General Pétain. Here, for the first time in the war, land mines were used on a large scale, and the attackers never reached the main French positions.

The riposte came three days later when Americans and French Moroccans counterattacked on July 18 along the right face of the salient created by the German drive to the Marne. Complete surprise was achieved by rushing the assault troops up in trucks under cover of darkness. Without any preliminary bombardment, the infantry advanced at dawn with 352 tanks and penetrated so deeply as to threaten the whole salient when other French and American troops attacked the opposite face. Before the Germans could pull out, they left 30,000 prisoners behind and suffered about the same number of killed and wounded.

The precept of motor transport set at Verdun in 1916 bore further fruit as entente generals learned that they could gain surprise unfailingly by these tactics. Dispensing with bombardment and bringing the assault forces up in trucks meant that there would be neither ammunition dumps nor troop concentrations to warn the enemy by means of his aerial observation.

The Amiens salient was next to be reduced as 13 British divisions attacked on Aug. 8 with 450 tanks while armoured cars manned by automatic riflemen spread confusion in German rear areas. On Sept. 2 another British attack struck the enemy in Flanders, and on the 12th an army composed of new American divisions wiped out the St. Mihiel (*q.v.*) salient.

The end was in sight during October as the British on the left and French in the centre rained blow after blow, striking by surprise when and where they were least expected. These victories stemmed in large measure from the pressure exerted on the enemy as the Americans on the right slugged their way forward in the 46-day battle of the Meuse-Argonne against an enemy using a fourth of his entire strength on a 20-mi. front in difficult terrain. (*See* also under names of various battles.)

VII. WORLD WAR II

1. The Post-World War I Reaction.—During the postwar years the reaction of the former entente nations was in the direction of defensive tactics. The casualties inflicted by the machine gun were remembered when the victories of the tanks were forgotten. This tendency went so far as to resemble in some instances the wishful tactical thinking of 1914 in reverse.

The French, with traumatic memories of two German invasions in half a century, translated their theories of the all-powerful defensive into the concrete and steel of the Maginot line—a bristling belt of underground forts and tank traps extending from the Vosges westward to the Ardennes, where it was believed that the hills and woods would turn back armoured columns. The British, as their modern counterpart of the Great Wall of China, had a defensive military philosophy, the main tenet of which was that postwar improvements in weapons added to the risks and perils awaiting a future aggressor.

The tactical euphoria of the former entente nations was shaken in the 1930s by successful Japanese, Italian and German aggressions. When the Spanish Civil War served as a rehearsal for Russian as well as German and Italian tactics, it was belatedly realized that improvements in weapons favoured the offensive to such an extent as to endanger laggards in preparations. Tanks were many times as fast and powerful as those of 1918; motorized artillery, on rubber tires, showed an enormous gain in mobility over horse-drawn, iron-wheeled vehicles; and motor trucks poured from the assembly lines by the thousands to solve the transport and supply problems of a new lightning warfare.

2. Early German Victories.—Any doubts as to the effectiveness of German preparations were dispelled during the first two years of World War II as Hitler's armoured columns swept on to victory after victory. The Maginot line was outflanked by German tanks which broke through in the Ardennes and drove from the Meuse to the Channel in a week, cutting off 335,000 men of the British expeditionary force and attached French units. It seemed an authentic miracle when these beleaguered troops were evacuated by sea from Dunkirk, leaving their heavy arms behind, as the German columns raced on to the occupation of Paris.

From the late summer of 1939 to the autumn of 1941 the Germans never met with a serious reverse in land warfare. Their triumphs were gained with such swiftness, such precision and economy of means that the blitzkrieg, or lightning war, was popularly accepted as a brilliant new tactical system. Actually it was the legitimate offspring of the infiltration tactics of 1918 mated with the tank tactics. There was nothing new that could not be explained by the gains of two decades in the offensive powers of such weapons as the tank (*q.v.*), motorized artillery and tactical aircraft. With a few exceptions such as antiaircraft guns, defensive weapons had lagged in the armament race while armour and artillery were leaping ahead from the 3 m.p.h. of 1918 to the 30 m.p.h. of 1938.

The French army of 1940 was essentially a World War I instrument, patched here and there with tactical changes, just as the Maginot line was in effect a modernized western front. Despite warnings that the enemy might strike through the gap in the Ardennes between the French and Belgian fortified lines, the French in the Sedan area were unprepared for German "tactics of the space and gap." Only three penetrations on a 12-mi. front, each no wider than 2,000 yd., were enough as the starting point of a major breakthrough. Like a flood enlarging holes in a dam, tanks and combat groups in armoured cars poured into the gaps, depending on surprise and speed as well as Stuka dive-bombers for flank protection. Their direction of attack was lateral as well as forward, the object being to widen the gaps for following German forces. Within four hours the invaders were overrunning command posts and communications centres in French rear areas too demoralized for effective resistance. The Maginot line had simply been by-passed and left behind by the torrent of armoured invasion which inundated northern France in a week.

Predictions that Hitler would meet his downfall in Russia were not upheld by military results of the first few months. The Russian army, like the prehistoric mastodon, seemed doomed to extinction by its very bulk as German armoured envelopments swallowed up prisoners by the division and corps. Political factors influenced tactics when Hitler's doctrines of racial superiority led to cruelties which drove Russian peasants into guerrilla warfare. Effective resistance of this sort, combined with Soviet scorched earth tactics and a seemingly endless reserve of man power, enabled the Soviet army to survive until the German transport bogged down in autumnal mud.

Even so, the tactics of Hitler's armies had been so successful during the first two years that a serious defect might easily have been overlooked. That was the apparent lack of preparation for amphibious tactics in a global war. Although the British Isles were desperately short of arms after the Dunkirk evacuation, the Germans had neither the training nor the equipment to land troops

across a few miles of water. In Crete they proved their mastery of airborne attack techniques, but a clumsy attempt at an amphibious combat landing ended in disaster.

3. The War in the Pacific.—After the United States and Japan entered the lists as enemies, the war in the Pacific necessarily consisted in large part of amphibious operations. And despite the tradition that the English-speaking peoples are never prepared for war, events showed that the U.S. forces had developed an effective system of amphibious combat tactics. Three continents were opened up to invasion by this system, which won a score of major victories without suffering a single major defeat. In the 1920s the "Orange" plans, adopted by the United States for offensive operations in the event of war with Japan, called for attacks on that nation's shield of fortified islands in the Pacific. By a directive (1927) of the joint board of the U.S. army and navy, the marine corps was given the mission of preparing for the conduct of landing operations.

There were few 20th-century precedents, though the Gallipoli failure of 1915 supplied no lack of object lessons. Weapons and techniques had to be improvized where none had existed before. Strange landing craft and amphibian vehicles evolved as inventors were encouraged to submit designs. Large-scale simulated assault landings were made annually in fleet exercises of the 1930s held at Caribbean and Pacific bases. New bases were established, new amphibious units formed, and new types of ammunition developed. As a result, the United States possessed on the eve of World War II what Maj. Gen. J. F. C. Fuller has described in his history of that conflict as "in all probability . . . the most far-reaching tactical innovation of the war." (J. F. C. Fuller, *The Second World War*, p. 207, Eyre & Spottiswoode, London, 1948.)

4. U.S. Amphibious Victories.—Within a year the outer barrier of Japan's island defenses was breached by U.S. ship-to-shore assaults. Months of detailed planning and rehearsal preceded each operation. Supply ships were "combat-loaded" so that tanks, trucks, artillery, fuel, rations and water would be made available to the landing force in the order needed. Intricate firing plans were drawn up for artillery and rocket bombardments to scorch the target area while armoured landing craft took the assault troops to the beaches under cover of air strikes. The transition from one element to another was the critical moment. Maneuver was seldom possible during the controlled chaos of the landings and repulse meant a disaster which could hardly be retrieved. Once the beachhead was won, special units unloaded cargo ships, established supply dumps and regulated traffic while the assault troops drove inland with the support of tanks and artillery as soon as they could be landed.

U.S. ship-to-shore assaults were conducted by troops using navy and marine techniques. The army trained special units for shore-to-shore assaults, utilizing the same landing craft. New Guinea was thriftily reduced by these troops in coastal landings which by-passed strong Japanese garrisons and left them behind to "wither on the vine."

The amphibious offensive had become by 1943 the most decisive tactical system of World War II, not only in the Pacific theatre but also in North Africa and Europe. Neither the Japanese nor the Germans ever found the clue to a successful defense. Landings in Morocco, Algeria, Sicily and Italy were followed by the climactic operation of June 6, 1944, when 4,100 ships put ashore five divisions complete with tanks and artillery on the beaches of Normandy. Nine days later in the Pacific an equally successful amphibious combat landing on Saipan brought American bombing planes within striking distance of Tokyo and led up to the assaults on Iwo Jima and Okinawa which made Japanese defeat inevitable.

5. Wide Variety of World War II Tactics.—So varied were the geographical and climatic conditions that it is difficult to generalize about the tactics of a war in which a score of major campaigns were being waged simultaneously in different parts of the world.

Tank battles on the plains of Russia began with tremendous artillery "preparations" and ended with armoured envelopments in which as many as 20 divisions were surrounded. In such instances the beleaguered forces were sometimes able to form a "hedgehog," or circular formation, and fight their way out of the encirclement with the aid of airborne supplies. In the long run it was a grinding war of attrition in which the Russians gained the upper hand largely as the result of arms and equipment delivered by Britain and the United States in spite of heavy losses suffered by sea convoys.

Armoured columns in the desert warfare of North Africa achieved a mobility which makes their operations instructive to the student of tank tactics. But General Rommel's defeat was foreordained by the inability of the Germans to mount an amphibious assault on Malta. The campaign in the desert was actually a battle of supply, and while the British held Malta they could provide air escorts for convoys of cargo ships in the Mediterranean.

On all fronts, special units equipped for special tasks were employed to an extent never known before. Infantry was the arm of decision in most operations, but it became standard practice to organize task forces ranging in size from platoons to divisions, reinforced by tanks, artillery, rocket launchers or such other support weapons as might be indicated for the specific mission.

So potent were the missile weapons of World War II that survival for the individual soldier depended on cover and concealment. Small infantry units took on increasing importance as experience taught that latitude of decision must be left to troops in direct contact with the enemy, since victory often depended on the initiative and intelligence displayed by platoon commanders.

Some of the infantry combat teams became standardized. The British commando units, made up of soldiers, sailors and marines organized on a permanent basis, conducted raids throughout the war. In Burma the British developed special penetration groups of infantry to operate behind the enemy's lines, attacking headquarters and supply dumps while being supplied by air.

All armies made an unceasing effort to gain a decision by the introduction of new weapons and tactics. But the German V-1 jet-propelled bomb came too late to change the outcome, as did the more formidable V-2 rocket after the Allies had broken through in Normandy and swept across France to the German frontier. (*See* ROCKETS.)

On the Allied side, the 2.36-in. rocket launcher and the 57-mm. and 75-mm. recoilless rifles provided the infantry with weapons which were tank-killers under favourable circumstances. The VT (variable time) artillery fuse enabled a shell to be exploded automatically in electronic reaction to waves reflected from the target itself. These tactical innovations seemed trivial, however, after President Truman's radio announcement of Aug. 6, 1945:

"Sixteen hours ago an American airplane dropped one bomb on Hiroshima, an important Japanese army base. That bomb had more power than 20,000 tons of T.N.T. . . . It is an atomic bomb. It is a harnessing of the basic power of the universe." (*See* ATOMIC ENERGY; *Bomb Explosions.*)

Thus, at the conclusion of World War II the participants were confronted by the fact that "the bomb" might render obsolescent all the tactics of victory. Even the discovery of gunpowder does not represent a comparable turning point in tactical history, for the first handguns were not as deadly as the crossbow. Nor did gunpowder have a rapid evolution, considering that the T.N.T. of the 20th century was only about twice as powerful as the explosives of the middle ages. Yet the world of 1945 had to adjust itself overnight to the necessity of revising all military standards of the past. (*See* ARMY; ARTILLERY; INFANTRY.)

VIII. THE KOREAN WAR

1. Intervention in Korea.—It is one of history's ironies that the first war of the strident new atomic age should have been waged with tactics reminiscent of the western front in 1917. Where the public had envisioned a "push-button" war of guided missiles, combat in Korea (1950–53) consisted for the most part of infantry fights with small arms on the platoon and company levels. (*See* KOREAN WAR.)

Called a "police action" at first, the intervention of 1950 proved during its first year to be the fourth most costly military effort of U.S. history. After a preliminary period of mobility, the United Nations and Chinese Communist forces faced each other in lines

of trenches and defenses in depth extending across the peninsula. Neither side attempted to hold its front in force. Bunkers and outposts on the main line of resistance sheltered combat groups whose duty it was to maintain contact with the enemy and warn of a large-scale attack. Patrols ranging in size from an infantry squad to a platoon crept through no man's land in the darkness as both sides found the ambush an effective tactic.

The Korean conflict taught that even in the atomic age an Asiatic peasant army using semiguerrilla tactics can be formidable in mountain terrain suited to its operations. (*See* MOUNTAIN WARFARE.) Atomic weapons would not have been effective in such a war, even if they had been considered, and the Korean experience made it appear unlikely that sound infantry tactics would soon become outdated.

2. Tactical Innovations of Korea.—The two great tactical innovations of the war were the combat helicopter and the revival of infantry body armour. Rotary wing aircraft had been developed too late for an extensive test in World War II, but in Korea the helicopter proved its value immediately in tactical as well as logistical respects. A U.S. brigade commander found it possible with the use of rotary-wing transportation to maintain combat control over units 25 mi. apart. When a U.S. squadron of transport helicopters reached the front, it was demonstrated that a battalion of infantry could be lifted in a few hours to the main line of resistance in mountainous country where an all-day march would have been necessary. On an occasion when an infantry company was surrounded, six helicopters flew in ten tons of ammunition and evacuated casualties, thus enabling the encircled troops to fight their way out of the trap.

The revival of body armour, after a lapse of several centuries, was made possible by 20th-century plastics. Nylon pads and thin slabs of Fiberglas were combined in a sleeveless vest weighing about eight and a half pounds and allowing freedom of movement. The armour was capable of stopping .45-calibre automatic pistol bullets, submachine gun slugs and most shell, mortar or grenade fragments of a velocity less than 1,100 ft. per second.

All U.S. combat troops in Korea were equipped with the garment before the conflict ended. On the basis of U.S. army and marine corps surveys, it was established that body armour prevented from 60% to 70% of chest and abdominal wounds while reducing the severity of 25% to 30% of the wounds resulting from penetrations. Aside from humanitarian aspects, this meant that a large proportion of the enemy's most effective antipersonnel weapons were rendered useless. The tactical value of body armour was increased by its contribution to morale. Troops on the defensive had their foxholes and trenches, but the vest-protected men advanced in the open during an attack, when protection was most needed. The result, according to U.S. infantry officers in Korea, was a marked increase in combative spirit.

3. Tactics of the Atomic Age.—At the end of the Korean war, the military problems of the atomic age were no nearer to solution because of lessons taught by that war. There was some reassurance, however, in the fact that neither side in an ideological conflict had even threatened to use atomic weapons, though it was known that Soviet Russia as well as the United States had conducted successful atomic tests. As further evidence that warring nations could practise restraint, it might have been cited that poison gas, one of the most deadly weapons of World War I, was not used in the next two wars, though all armies were in possession of far more destructive gases than those of 1918. Nor was any attempt made to gain a military advantage by the possibilities for wiping out entire populations offered by germ warfare.

During the first decade of the atomic age, the U.S. tests conducted at Bikini atoll in the Pacific and Yucca Flat in Nevada encouraged soldiers to believe that tactics might be adjusted to the new weapon by means of troop dispersion on a scale never envisioned before. Then came the announcement of the hydrogen bomb and predictions that weapons with fantastic destructive power measured in terms of 45 megatons (45,000,000 tons of TNT) were being developed. (In 1961 the U.S.S.R. detonated a device of even higher yield.) Contemplating such a prospect military men could only admit that they knew of no tactical antidote to a force capable of wiping out a province or a metropolitan city with a single explosion. It was no longer war when such weapons were used; it was sheer insane destruction. And there was not much consolation in the thought that an enemy could be paid back in kind.

Fears of intercontinental atomic bombing raids led in the late 1940s to popular clamour for great fleets of strategic aircraft. But during the years following the Korean conflict, future trends were indicated by the development of an entire new family of low-yield atomic weapons suited to battlefield use against tactical targets. Although the nature of most of these weapons was kept a military secret, it became public knowledge that nuclear artillery and rockets were included.

A result of these trends was the pentomic infantry division announced by the U.S. army in 1957. Firepower, mobility and dispersion suited to the atomic age were the goals sought in the most sweeping changes made by any army up to that time. The three infantry regiments of the triangular division, with their nine battalions, were replaced by five battle groups, each comprising approximately 1,400 officers and men. Although total numbers were reduced, the "foxhole strength" of the pentomic division was increased.

In 1961 the pentomic division, designed for employment in nuclear warfare, was abandoned because it proved too cumbersome and inflexible for use in "brushfire" wars involving limited forces and conventional weapons. Its place was taken by a new divisional structure consisting of an "all-purpose" divisional base with three brigade headquarters to which could be attached varying numbers and types of combat maneuver battalions (*see* DIVISION, MILITARY). This reorganization provided a division whose size (10,500 to 19,950 men) and equipment could be tailored to each specific mission and to the type of terrain encountered in its accomplishment. Other results of the change were improved balance between nuclear and non-nuclear firepower, greater internal flexibility and an improved command and control structure.

At about the same time a unified command was established to include the strategic army corps (STRAC), designed for fast deployment by air, and the tactical air command (TAC) of the U.S. air force. Thus was created a mobile striking force of ground troops adequately supported by aviation units. This new command helped alleviate an army complaint that ground forces were without adequate tactical air support since the diversification of command caused by the separation of the army and air force in 1947.

Still another change in tactical thinking occurred during the early 1960s with the establishment of special forces for carrying on small-unit guerrilla warfare behind enemy lines or co-operating with indigenous populations in antiguerrilla operations.

(LN. MS.)

TACTICS, NAVAL: *see* NAVAL STRATEGY AND TACTICS.

TACUAREMBÓ, the largest department of Uruguay, located north of the Río Negro in the north central part of the nation, has an area of about 21,000 sq.km. (8,114 sq.mi.) and a population of

136,421 (1962 est.), of whom approximately 21,000 live in the departmental capital, also called Tacuarembó. Tacuarembó is a typical ranching department of the Uruguayan interior, with the 1951 livestock census counting 817,126 cattle and 2,338,538 sheep. Corn, tobacco, peanuts, rice and forage crops are the leading crops. Construction of the hydroelectric dam at Rincón del Bonete on the Río Negro, which supplies power for Montevideo, created a large lake in the department. (M. I. V.)

TACUTU (TAKUTÚ), a tributary in the Amazon river system. It rises in the Serra Uaçari on the Brazil-British Guiana border and flows northward and then westward and southward to its junction with the Uraricoera river about 20 mi. above Boa Vista, where the two rivers form the Rio Branco. On its northward course the Tacutu flows along the western edge of the Rupununi savannas and forms a section of the Brazil-British Guiana boundary. Upon turning westward it receives the waters of the Ireng (or Maú) river, which also forms part of the Brazil-British Guiana boundary. (D. R. D.)

TAD: *see* DORGAN, THOMAS ALOYSIUS.

TADZHIK (TAJIK), the original Iranian population of Afghanistan and Turkistan. Tadzhik constitute a majority of the population of Soviet Tajikistan (*see* TADZHIK SOVIET SOCIALIST REPUBLIC); in the 1960s they numbered about 1,400,000 in the U.S.S.R., with more than 300,000 in Uzbekistan. They comprised about one-third of the population of Afghanistan, where their communities have been reported near Kabul in the Herat region, and in a number of localities north of the Hindu Kush.

Tadzhik were the heirs and transmitters of the central Asian sedentary culture that diffused in prehistoric times from the Iranian plateau into an area extending roughly from the Caspian sea to the borders of China. Here were built villages of flat-roofed mud or stone houses along streams and rivers that irrigated fields of wheat, barley and millet, and gardens famous for melons and a variety of fruits. Crafts were highly developed, and towns along the caravan routes linking Persia, China and India were centres of trade networks in the area.

Turks, and later Mongols, flowed westward into the area, and Pushtu speakers (Afghans) gradually pushed northward. As these nomadic peoples settled, they adopted Iranian culture, but in Turkistan many of the Iranians adopted Turkic speech.

The name Tadzhik refers to the traditionally settled Caucasoid people who have retained Iranian speech. Most speak dialects of Persian, but the Mountain Tadzhik or Galcha in the Pamir mountains speak dialects of two eastern Iranian languages, Pamir and Yagnobi.

See D. N. Wilber *et al., Afghanistan: Its People, Its Society, Its Culture* (1962); T. Fitzsimmons *et al., U.S.S.R.: Its People, Its Society, Its Culture* (1960). (EL. B.)

TADZHIK SOVIET SOCIALIST REPUBLIC (TADZHIKSKAYA SOVETSKAYA SOTSIALISTICHESKAYA RESPUBLIKA; TADZHIKISTAN, or TAJIKISTAN), a republic of the U.S.S.R. which achieved the status of a federal union republic on Dec. 5, 1929. Situated in the southeast of Soviet central Asia, the republic is bordered on the south by Afghanistan and on the east by the People's Republic of China. Area 55,212 sq.mi. The capital is Dushanbe, which, from Dec. 1, 1929, to Nov. 11, 1961, was called Stalinabad.

Physical Geography.—In general the Tadzhik S.S.R. is high mountain terrain. Its whole eastern part covers the high-level valleys or *pamirs*. The country is traversed by many mountain ranges generally extending east-west, and including the Zeravshanski and Gissarski ranges in the west, and the Peter I (Petra Pervogo), Trans-Alai (Zaalaiski) and North and South Alichurski ranges in the Pamirs (*q.v.*). The north-south Sarykolski range forms the eastern frontier of the republic. Communism peak (formerly Pik Stalina; 24,590 ft.) and Lenin peak (Pik Lenina; 23,405 ft.) in the north of the Pamirs, and Karl Marx peak (22,067 ft.) in the south are the highest mountains in the Soviet Union.

South of Mt. Communism lies the 50-mi. Lednik Fedchenko, the longest continental ice stream in the world. With the exception of the Tadzhik section of the Syr-Darya (Jaxartes) in the Fergana valley, of the Zeravshan river which loses itself in the Uzbek desert near Bukhara, and of the Markansu river which flows into Sinkiang, all the glacier-fed streams are right-bank tributaries of the Amu-Darya (*q.v.*, or Oxus). The Amu-Darya rises in the Afghan Hindu Kush as the Vakhan-Darya and, as the Pyandzh (from Persian *panj*, meaning five; *i.e.*, the five streams which it collects on its way), it forms most of the frontier between Afghanistan and the Tadzhik S.S.R. It then receives the Vakhsh river, which rises in the Kirgiz S.S.R. and is called first Kyzyl-Su ("red water" in Uzbek), and lower down Surkh Ab ("red water" in Persian).

There are many lakes in the Pamirs formed either by glaciers or as a result of avalanches (produced by earthquakes) which dammed existing streams. The largest glacier-formed lake is Kara-Kul, 141 sq.mi. and 780 ft. deep. Among lakes of such tectonic origin the largest and most recent is Sarezkoye Ozero, 38 mi. long and 1,657 ft. deep, formed in 1911.

The country has three types of climate. In the lowlands it is hot and dry, with a yearly rainfall averaging 10 in. and temperatures varying between 31° C. (88° F.) in July and 3° C. (38° F.) in January. In the foothills there is more rainfall and it is cooler. In the high mountains above 10,000 ft. there is only 3 in. of yearly precipitation and the yearly average temperature is below freezing point.

The northwestern lower slopes are well covered with forest. Many varieties of vegetation are represented, from saxaul scrub and jungle grass, through deciduous and coniferous forest to alpine pasture. Animal life is also varied. In the southern lowlands tigers, deer and many kinds of water birds are found. In the higher plateaus there are antelopes and huge lizards up to 4½ ft. long, and in the Pamirs there are bears and mouflons.

History.—The Tadzhik (*q.v.*) peoples are of Persian-speaking Iranian stock. They were included in the empires of Persia and of Alexander the Great of Macedonia. In the 8th century the Arabs crossed the Amu-Darya, conquered Sogdiana (*q.v.*; Transoxiana) which was inhabited by Tadzhiks, and called it Mavera un nahr ("land beyond the river"). Two centuries later the first Turkic invaders (from the northeast) seized Mavera un nahr, and in time, as both conquered and conquerors were Muslim, many Tadzhiks, especially those in the valleys of Syr-Darya and Amu-Darya, became turkicized.

Until mid-18th century the Tadzhiks were part of the amirate of Bukhara (*q.v.*), but then the Afghans conquered lands south and southwest of the Amu-Darya with their Tadzhik population, including the city of Balkh (*q.v.*), an ancient cultural Tadzhik centre. Another partition of the Tadzhik territory took place in 1895 when an Anglo-Russian commission fixed the northern frontier of Afghanistan on the Pyandzh river and separated the Russian and Indian empires by an Afghan corridor on the Vakhan-Darya extending to the Chinese frontier.

After the Russian Revolution of 1917 a considerable part of the Tadzhik people was included in the Turkistan Autonomous Soviet Socialist Republic established in April 1918. On Aug. 23, 1920, the revolution was extended to the khanate of Bukhara, which embraced most of the territory occupied by the modern Tadzhik S.S.R. In Oct. 1920 the Bukhara People's Soviet Republic was declared in being, and early in 1921 the Soviet army captured Dushanbe and Kulyab. From 1922 to the summer of 1923 Tadzhikistan was the scene of the Basmachi revolt, and rebel bands under Ibrahim Bek operated in Eastern Bukhara until 1926. In 1924 the Tadzhik A.S.S.R. was created as part of the Uzbek S.S.R.; in Jan. 1925 a Special Pamirs *oblast* was created out of the Kara-Kirgiz and Tadzhik parts of the Pamirs; and in Dec. 1925 this *oblast* was renamed the Gorno-Badakhshan Autonomous *oblast*. Tadzhikistan was thus composed of the following former administrative units: Eastern Bukhara, 7 volosts (rural districts) of the Samarkand *uyezd* (county), the 5 southern volosts of the Khodzhent (later Leninabad) *uyezd*, and 6 volosts of the Pamirs region. On Dec. 5, 1929, the status of the republic was raised to that of Soviet Socialist Republic.

Collectivization of agriculture was carried out in 1928 and 1929

in the face of considerable opposition. There were later periodical purges of the council of ministers and the party apparatus, including one in 1961.

Population and Administration.—According to the 1959 census the population was 1,979,897, including 1,051,164 Tadzhiks (53.1%), 454,433 Uzbeks (23%), 262,610 Russians (13.3%), 56,893 Tatars (2.9%), 26,921 Ukrainians (1.4%), 25,635 Kirgiz (1.3%), and 12,551 Kazakhs (0.6%). The density of population was 13.9 per sq.km. (about 36 per sq.mi.). The most thickly populated areas are the Leninabad district in the north of the republic and the Gissar and Vakhsh valleys. One-third of the population are town dwellers living in 14 towns and 31 "settlements of town type." The main towns are Dushanbe, Leninabad (*qq.v.*), Ura-Tyube, Kulyab and Kurgan-Tyube.

In the absence of any official statistics it can be assumed that all the inhabitants of the republic other than Russians and Ukrainians are actual or nominal adherents to the Muslim religion.

The government of the Tadzhik S.S.R. is the standard one for union republics. Control over every form of government, economic, social and cultural activity is exercised by the communist party. After the administrative reorganization carried out in 1962 the republic consisted of the Gorno-Badakhshan Autonomous *oblast* (*q.v.*) and a number of *raions* under direct republican administration. Leninabad *oblast* was abolished.

Education and Culture.—The culture of the Tadzhiks, who constitute a little over half of the population, is Iranian, their language closely resembling the Persian spoken in Iran and Afghanistan, although it has been written exclusively in Cyrillic (Russian) characters since 1940. About 27% of the population is made up of various Turkic elements, mainly Uzbek, and these, with the exception of a few small tribes in the south, stubbornly resist Iranization.

Several newspapers are published in the Uzbek language which is taught to Uzbeks attending school. During the Soviet period the Tadzhiks have laid claim to some of the principal Persian poets such as Rudaki and Omar Khayyam. Sa'di, Hafiz and Jami are described as "organically entering" the history of Tadzhik literature.

In the early 1960s there were more than 2,600 schools with more than 330,000 pupils, and about 200 kindergartens with 16,000 children. There were also 80 schools for young industrial workers with 8,500 pupils, more than 100 schools for young agricultural workers with 2,700 pupils, 25 "middle" special training establishments with 4,200 pupils, and 7 higher educational establishments (including the Tadzhik State university, established 1948) with 18,200 students. A branch of the U.S.S.R. Academy of Sciences was established in Dushanbe in 1941 (this became an independent academy in 1951). In Dushanbe there are radio and television transmitters broadcasting in Tadzhik, Russian and Uzbek languages.

The Economy.—The economy of Tadzhikistan is mainly concerned with the growing and processing of cotton. Industry is principally light and apart from cotton ginning and textile weaving it is connected chiefly with food processing. In agriculture the main crop is cotton, but fruit is grown extensively as well as food grains and technical crops. There is a considerable cattle-breeding industry.

In the early 1960s there were about 350 kolkhozes (collective farms) and 40 sovkhozes (state farms) in Tadzhikistan. Half of the total sown area was under irrigation. The main canals are the Vakhsh, the Great Gissar, the Great Fergana, and the Northern Fergana. A large area is under cotton and the yields per acre are among the world's highest.

On the unirrigated lands, principally on the northern slopes of the Turkistan range and in the southeast of the republic, food grains (wheat, barley and millet) are grown and oil grains (mainly flax) are cultivated in the southeast. Stock breeding includes sheep, horned cattle, pigs, karakul sheep, angora goats, Lokai horses and yaks (in the eastern Pamir).

There are cotton-ginning factories in all the cotton-producing valleys, the principal ones being in Dushanbe, Regar and Kurgan-Tyube. Most of the textile weaving is carried on in the Dushanbe cotton *kombinat* (combine). Leninabad is an important centre of the silk-weaving industry. In the early 1960s large factories for the manufacture of carpets and woolen goods were built at Ura-Tyube. Cotton-seed oil processing is allied to cotton ginning, the principal centres being Kanibadam, Leninabad, Kurgan-Tyube and Shaartuz.

There are fruit canneries at Kanibadam, Leninabad, Chkalovski and Regar and wineries at Dushanbe, Leninabad and Ura-Tyube. Minerals that are being exploited include lead and zinc (Kansai), fluorspar (Takob) and brown coal (Shurab); oil is produced at Kim and Nefteabad. In its hydroelectrical resources the Tadzhik S.S.R. occupies the second place in the U.S.S.R. (after the Russian S.F.S.R.), the main power stations being at Kairak-Kum on the Syr-Darya and at Perepadnaya on the Vakhsh canal. During the 1959–65 seven-year plan a gas pipeline from the Uzbek S.S.R. was planned and under construction.

Communications.—There are 258 km. (160 mi.) of standard- and 300 km. (186 mi.) of narrow-gauge railway lines. The main line, connecting the national network, is from Termez to Ordzhonikidzeabad. From Dushanbe to the Vakhsh valley and thence to Kulyab there is a narrow-gauge line. There are main highways between Dushanbe and Khorog, Khorog and Osh, Dushanbe and Ura-Tyube; Kurgan-Tyube and Kulyab also have road links with Dushanbe.

The Amu-Darya is navigable below Faizabadkala. Air transport is important and airlines join Dushanbe with Moscow, Tashkent, Baku and other towns. (G. E. Wr.; K. Sm.)

TAEGU, a city in the Republic of (South) Korea, 60 mi. N.W. of Pusan on a tributary of the Naktong river. It is an important commercial centre for southeastern Korea. Textiles are a major industry, with more than 200 factories engaged in silk spinning and about 100 in cotton spinning. The city is an important market centre for apple growers, and a large cattle market is also held there periodically. In 1950 during the Korean War, Taegu was captured by the Communist forces, but was later recaptured by United Nations troops. In 1960 the population was 678,277.
(S. McC.)

TAEJON, a city in the Republic of (South) Korea, 125 mi. N.W. of Pusan and 90 mi. S. of Seoul. Taejon is a relatively new town constructed as the junction point of a large rail network developed during the Japanese control of Korea (1910–45). This large and important commercial and industrial centre suffered extensive battle damage during the Korean War, but has been largely rebuilt. Textile factories and consumer goods industries are Taejon's major sources of employment. Its central location in southern Korea makes it a rail and air centre. The population in 1960 was 229,393. (S. McC.)

TAEL. The tael (Chinese, *liang*), a Chinese unit of weight, when applied to silver was long used as a currency unit. There have been many taels of varying weight, generally in the neighbourhood of 1⅓ oz.

The currency tael was seldom minted in the form of a coin, but served as a standard money of account, actual transactions being completed with ingots of silver, with bank notes or checks expressed in taels, or with silver coins, especially the Spanish and Mexican dollars which flowed into China in great volume in the 18th and 19th centuries.

Bar silver imported into China was remelted and cast in ingots weighing about 50 taels, of a special shape called "shoes" (from the Dutch word *schuyt* meaning boat) of *sycee* (literally, fine silk, hence, fine silver). Each shoe was marked by the public assaying office with its weight and fineness, from which data its value in currency taels was computed. Sycee formed a large part of bank reserves down to 1933.

The most important currency tael was the Shanghai tael, adopted in 1857 to replace the Spanish dollar which was becoming scarce. The fine-silver equivalent was 518.512 grains. Since China was on a silver standard while the rest of the world was on a gold standard, the exchange value of the Shanghai tael fluctuated with the price of silver in London and New York, ranging from around 6*s.* or $1.50 before 1873 to as low as 1*s.* 2*d.* or 28 cents in 1931. It was the basis for wholesale trade and for-

eign exchange transactions in China's most important commercial city.

Of the numerous other taels used as moneys of account at various times and places, two deserve mention. The *k'uping* or treasury tael was used under the Manchu dynasty for the payment of taxes; 100 *k'uping* taels equalled 109.60 Shanghai taels. The *Haikwan* or customs tael was adopted in 1858 for the valuation of imports and exports and for the fixing of duties; 100 *Haikwan* taels equalled 111.40 Shanghai taels.

From ancient times the money of the masses for small transactions was the cash (*q.v.*) but from the latter part of the 19th century retail trade gradually began to be conducted with Mexican and, later, Chinese silver dollars, fractional silver coins, and 10-cash copper pieces.

Finally, in April 1933, the tael was officially abolished and replaced by the new Chinese standard dollar or *yuan* at a fixed rate of Shanghai taels 71.50 equal 100 yuan. The new coin weighed 412 grains, 0.880 fine, and its exchange value, of course, fluctuated with the world price of silver.

TAENIODONTA, an extinct order of North American mammals of the Paleocene and Eocene epochs (a period extending from 40,000,000 to 75,000,000 years ago). The single known family Stylinodontidae includes two subfamilies, Conoryctinae and Stylinodontinae. Conoryctinae, rather generalized forms with no outstanding peculiarities, did not survive the Paleocene. Stylinodontinae became progressively and more curiously specialized, culminating in forms with extremely short and broad skulls; deep, massively built lower jaws; rootless teeth; and limbs of the digging type, tipped by very large, long, laterally compressed claws. The canines were the outstanding features of cranial and dental evolution, the rest of the dentition becoming accessory and to a degree subordinate to them in a manner unique among mammals. Claws and teeth together suggest adaptation to a specialized diet, the nature of which is unknown. Some superficial resemblance exists between taeniodonts and ground sloths, but this is certainly due to similar habits and not to common ancestry. Taeniodonts may represent an independent and isolated offshoot of the earliest Insectivora.

TAFFETA, a term strictly denoting a light, thin and plain texture of silk possessing a high sheen or gloss and finished in a manner that imparts to it the "rustle" or "scroop" peculiar to certain types of closely woven, plain silk textures produced from spun silk yarn. The warp and weft may be of corresponding denier or counts, approximately, while the number of warp threads and picks per inch may also correspond.

Taffeta is sometimes embellished with a very small brocade or "float" figuring of warp or weft, and may either be woven from skein-dyed yarn, or else piece-dyed after weaving. Some qualities of taffeta fabrics are artificially "loaded," *i.e.,* weighted, with metallic salts, and are therefore more liable to split or crack when creased or folded. It is used chiefly for dress, millinery and similar purposes.

The word "taffeta," however, is now applied as a description of many other varieties of fabrics produced from silk, wool, cotton and combinations of these materials.

Chiffon taffeta is of a softer texture and finish than that of ordinary taffeta. One variety of taffeta is produced from a silk warp and Botany wool weft; another variety, described as "wool taffeta," is woven entirely of fine wool yarn both for warp and weft, which makes a fine and close texture of light weight, with a smooth surface.

Some varieties of taffeta are produced from a cotton warp and fine Botany weft, while others are woven entirely with twofold cotton yarn of fine counts, and finished with a stiff "finish" to simulate the "scroop" peculiar to silk fabrics.

TAFILÁLT or TAFILET (*i.e.,* "The Country of the Filáli," as its inhabitants are called, because descended from the Arabian tribe of Hilál, settled there in the 11th century), important oasis of the Moroccan Sahara, ten days' journey south of Fez, across the Atlas. It is celebrated for its dates, to the successful cultivation of which, soon after the arrival of an ancestor of the reigning dynasty of Morocco (hence called the Filáli Sharifs, *i.e.,* descendants of Mohammed) *c.* A.D. 1250, the dynasty owed its rise.

Tafilált is a succession of ksurs (fortified villages) and palm groves which correspond to the zone irrigated by the Wad Ziz, and stretch over a length of about 50 km. The largest centre is Bu-Am, an important market.

The sedentary natives, who were exploited by the Aït-Atta nomads, live in poverty on their palm groves. The industry is the tanning of goatskins to obtain *filali* leather, which has a great reputation. The *takaut* (*Tamarix articulata*) yields gall for tanning. After 1648 it was the custom of Moorish sultans to dispatch superfluous sons and daughters to Tafilált. In Ifli, the central portion, formerly existed the town of Sigilmasa, founded by Miknása Berbers in 757 B.C. It was on the direct caravan route from the Niger to Tangier, and attained a considerable degree of prosperity.

The first European to visit Tafilált was Rene Caillie (1828), the next Gerhard Rohlfs (1864). A later visit to the oasis by W. B. Harris is described in his book *Tafilet* (London, 1895).

TAFT, LORADO (1860–1936), U.S. sculptor, lecturer and teacher, was born at Elmwood, Ill., on April 29, 1860. He graduated from the University of Illinois, Urbana, where he first worked in sculpture, in 1879, and then studied at the École des Beaux-Arts in Paris until 1883, remaining in that city with but brief interruption until 1885. Establishing himself in Chicago in 1886, he taught sculpture at the Art institute and began his long career of public lecturer. He was elected to the National Academy in 1911. He participated actively in the formation of plans for public education in art, and served (1914–17) as director of the American Federation of Arts.

Aside from many portraits, included among his works are: "Sleep of the Flowers" and "Awakening of the Flowers" for the Columbian exposition (1893), "Despair" (1898), "Solitude of the Soul" (1900), the colossal "Black Hawk" at Oregon, Ill. (1912), Thatcher Memorial fountain, Denver, Colo. (1918), and the "Fountain of Time" (1920), intended as part of a monumental complex of sculpture in Chicago.

In 1903 he published *The History of American Sculpture,* the first comprehensive work on the subject. His *Some Modern Tendencies in Sculpture* was published in 1920.

He died at Chicago on Oct. 30, 1936. (J. C. T.; A. T. G.)

TAFT, ROBERT ALPHONSO (1889–1953), United States senator from Ohio and son of William Howard Taft, 27th president of the United States, was born in Cincinnati, O., on Sept. 8, 1889. He attended the public schools of Cincinnati and the Taft school at Watertown, Conn.; was graduated from Yale university with a B.A. degree in 1910 where he stood first in his class; graduated from Harvard university with an LL.B. degree in 1913 where he was first in his class and editor in chief of the *Harvard Law Review.* In 1913 he passed the Ohio bar examination with highest honours in the state. In 1914 he married Martha W. Bowers.

After practising law in Cincinnati, Taft served during World War I, 1917–18, as assistant counsel for the United States Food administration. In 1919 he was counsel for the American Relief administration in Europe. From 1920 through 1938 he practised law in Cincinnati, establishing a reputation as one of the ablest lawyers in Ohio. During this period, 1921–26, he was a member of the Ohio house of representatives where he became Republican floor leader and speaker of the house. He served in the Ohio senate in 1931 and 1932.

Shortly after his election to the United States senate in 1938, Taft became a national political figure. He was re-elected to the senate in 1944 and re-elected again in 1950 by a majority of 431,000 votes, one of the largest ever given a candidate for U.S. senator from Ohio. With each U.S. senator being responsible only to one of 48 constituencies, leadership in the senate is often more titular than real. Taft, however, excelled in the essential political

art of compromise. His exceptional intellect and almost legendary capacity for work gave him a mastery of legislative facts far beyond the narrow range of committee specialization. His honesty, integrity and patriotism were never responsibly questioned. His Republican colleagues in the senate selected him in 1947 as chairman of the senate Republican policy committee, a position he held until his election as senate majority leader in Jan. 1953. It is difficult for anyone outside the congress to evaluate precisely the worth of one of its members. Much of the actual work is done in closed committee meetings and in informal conferences. The congress itself is the only point at which all the myriad facts and pressures coalesce. Perhaps the most meaningful tribute to Senator Taft's stature is that he was regarded by his colleagues, Democrats as well as Republicans, with unprecedented respect and esteem.

Taft lacked many of the traits commonly associated with a good politician in the United States. He was thought by many to be cold and austere. His genial personality and gentle humour were reserved for friends and for direct personal contacts. He had no trace of demagoguery. His appeal was to logic, rarely to emotion. He championed unpopular causes. He disdained the use of wit, eloquent speech and brilliant metaphor. He spoke bluntly, armed only with facts and simple statements of his principles. His willingness to make an unequivocal statement on any controversial issue frequently embarrassed his political managers. Typical was his forthright condemnation of the Nuremberg trials as vengeance by the victors decked out in the trappings of justice. Whether or not enemy leaders were tried under *ex-post facto* laws was not an issue that would ever come before the senate. His bold expression of his convictions contrary to prevailing public opinion flouted all conventional norms of good politics.

Taft was generally regarded as a conservative in American politics. In recognition of his leadership of the more conservative political party, he was nicknamed "Mr. Republican" by the American press. But even in the field of social-welfare legislation, he was not inflexibly wedded either to the status quo or to his former position. He was an original sponsor of legislation providing for public housing for low-income groups. He sponsored legislation authorizing federal aid to state governments for the improvement of medical care and education and of the living standards of the aged.

On the other hand, Taft was an uncompromising opponent of legislative measures which, in his judgment, undermined personal incentives for economic betterment or demanded excessive government intervention in the lives of its citizens. He consistently opposed compulsory health insurance on the ground that government control of the medical profession made the promised benefits illusory. He opposed peacetime price and wage controls. His political philosophy was perhaps best stated in 1948 when he described the "one great issue in the world today" in these words: "It is that of government operated by a free people on the basis of freedom and justice for every individual, on the one hand, against the totalitarian state on the other—the kind of state which concentrates in a central government power to direct the lives of all its people, its agriculture, its commerce and its industry." Taft often defined the basic domestic issue in American life as one of "liberty versus socialism."

It was in the field of labour law that Taft won his greatest legislative fame. In the nation-wide transportation strike of 1946, Pres. Harry S. Truman made a personal appeal to the congress for legislation authorizing him to draft striking workers into the army "on such terms as he might impose." The house of representatives passed the bill immediately, and the senate seemed likely to follow suit. Notwithstanding the intense pressure for drastic action, Taft blocked it in the senate by utilizing its rule of unlimited debate.

When the Republican party won control of congress in the elections of 1946, Taft had the choice of becoming chairman of either the senate finance committee or the senate labour committee. Typically, he chose the more politically explosive assignment. As chairman of the labour committee he guided to passage over a presidential veto the Labor-Management Relations act of 1947, popularly known as the Taft-Hartley law. He defended it as imposing on labour unions obligations comparable to those imposed on management. Labour union leaders, almost without exception, denounced it as a "slave labour" law. They mobilized their forces to defeat him in 1950. No senatorial campaign in U.S. history attracted so much nation-wide interest. Taft's overwhelming victory was interpreted by his followers as proof that no economic group in America is cohesive enough to decide the outcome of an election through bloc voting on isolated issues.

Prior to United States participation in World War II, Taft opposed measures calculated to increase the chances of involvement. For that stand, he was frequently criticized as an "isolationist." After the war he recognized the United States' new position of world leadership. He urged ratification of the United Nations charter. Because of Soviet Russia's intransigence, however, Taft had little faith in the U.N. as a shield against aggression. In opposition to the Truman administration and many Republicans as well, he advocated reduced foreign aid expenditures, greater emphasis on retaliatory air power and less on ground defense forces in western Europe, increased attention to far eastern problems, and congressional approval of executive decisions to send American troops abroad.

Taft was three times an unsuccessful candidate for the Republican nomination for president. In the Republican national convention of 1940, he lost the nomination to Wendell Willkie; in 1948 to Thomas E. Dewey; and in 1952 to Dwight D. Eisenhower. Despite the bitterness of the prenomination struggle in 1952, Taft and his followers united wholeheartedly behind Eisenhower. It was widely predicted that the differences between Eisenhower and Taft, particularly on foreign policy issues, would make close cooperation between the White House and the Capitol impossible. Taft, however, was determined to make the first Republican administration in 20 years an unqualified success. Most observers agreed that he was eminently successful in bridging the constitutional gap dividing executive and legislative authority which is so essential in the American ideal of freedom and yet so often productive of discord and inaction.

Taft died of cancer in New York city on July 31, 1953. His body lay in state in the rotunda of the Capitol—an honour accorded to only 12 others. He was buried near his home in Cincinnati in the cemetery of the Indian Hill church.

TAFT, WILLIAM HOWARD (1857–1930), the 27th president and tenth chief justice of the United States, was born in Cincinnati, O., on Sept. 15, 1857. His father, Alphonso Taft, was attorney general in Pres. U. S. Grant's cabinet (1876–1877) and minister to Austria (1882–84) and to Russia (1884–85). William Howard Taft graduated second (salutatorian) in his class at Yale college in 1878, and at the law school of Cincinnati college, in 1880, dividing the first prize for scholarship. In the same year he was admitted to the Ohio bar. In 1881 he was appointed assistant prosecuting attorney of Hamilton county (in which Cincinnati is situated), but resigned in 1882 on being appointed U.S. collector of internal revenue for the first district of Ohio.

In 1883 he returned to the law. From 1885 to 1887 he served as assistant solicitor of Hamilton county, and in the latter year was appointed judge of the superior court of Ohio, to fill a vacancy, being elected in the next year. In 1890, he was appointed solicitor-general of the United States by Pres. Benjamin Harrison. In 1892 he was appointed U.S. circuit judge for the sixth circuit.

From 1896–1900 Taft also served as professor and dean of the law department of the University of Cincinnati.

Governor of Philippines.—In 1900 he was appointed by Pres. William McKinley to the presidency of the Philippine commission. He served as such from March 13, 1900, to Feb. 1, 1904, becoming governor ex officio on the establishment of civil government, July 4, 1901 (*see* PHILIPPINES, REPUBLIC OF THE). The delicate matter of confiscated church lands was arranged by Taft in an interview with Pope Leo XIII, in the summer of 1902. The pope sent a special delegate to appraise the

lands, and the sum of $7,239,000 was paid for them in Dec. 1903.

Secretary of War.—In Feb. 1904, Taft returned to the United States to become secretary of war. In Sept. 1906, on the downfall of the Cuban Government and the intervention of the United States he took temporary charge of affairs in that island (Sept.–Oct.). In the next year (March–April) he inspected the Panama canal and also visited Cuba and Porto Rico. He again visited the Philippines to open the first legislative assembly (Oct. 16, 1907). On this tour he visited Japan, and on Oct. 2, at Tokyo, made a speech which had an important effect in quieting the apprehensions of the Japanese on the score of the treatment of their people on the Pacific coast. While secretary of war, Taft entirely reorganized the work of carrying on the construction of the Panama canal, and selected Col. George W. Goethals, whom President Roosevelt put in entire charge of the work. From that moment the enterprise assumed a new vigour, the work was completed and was opened to traffic in 1913.

President.—In 1908 Taft was favoured by President Roosevelt as his successor, and in the November election, was victorious over William Jennings Bryan, the Democratic nominee, by a popular majority of 1,269,900 votes (Taft, 7,679,006; Bryan, 6,409,106) and by a majority of 159 votes in the electoral college. In accordance with his pre-election pledge, he called the Congress to meet in extra session on March 15, 1909, to revise the tariff. The final bill known as the Payne-Aldrich Act was approved by the president on Aug. 5, 1909, although in many respects it was not the measure he desired. The income of the Government under the Dingley tariff had proved inadequate to meet its current expenses, the estimated deficit for the fiscal year ending July 1, 1909, being $100,000,000. He therefore recommended to the Congress the adoption of resolutions to amend the Constitution by expressly granting Congress power to levy an income tax without apportionment among the several States. For the purpose of meeting the immediately anticipated deficiency in the revenues, he recommended the adoption of a provision in the Tariff Bill imposing an annual special excise tax upon corporations organized for profit, measured by a percentage on their net incomes. Pursuant to these recommendations a proposed amendment to the Constitution was passed by both Houses of Congress, afterwards ratified by the requisite number of the States, and became the 16th amendment, and there was included in the Payne-Aldrich Act a provision imposing the proposed annual special excise tax upon corporations, measured by 1% of their net incomes.

Payne-Aldrich Tariff Act.—While the Payne-Aldrich Act was much criticized, because it failed to reduce duties on imports to the extent expected, yet it marked a distinct step towards a lower scale of import duties, and opened the door to the free exchange of commerce with the Philippines. By the enactment of the maximum and minimum tariff provisions, it placed a powerful weapon in the hands of the American Government for the protection of American commerce against unduly discriminatory practices by foreign Governments. It also, for the first time in American history, provided for the establishment of a tariff board to study the questions which lie at the foundation of the protective system.

While Congress was considering the Tariff Bill, the president called upon the heads of the departments of Government to prepare, in advance of the usual time, their estimates for the fiscal year ending June 30, 1911, admonishing them to reduce expenses wherever it could be done. These estimates were then considered by the president and cabinet, and for the first time in American history, a comprehensive budget was prepared. As a result of these efforts, a cut was made of about $55,000,000 in the estimates for the fiscal years 1910 and 1911. In June 1910, the Congress granted the president's request for an appropriation to enable him to employ competent persons to study the methods of transacting the public business of the executive departments and other Government establishments, and to recommend such legislation as might be necessary to carry into effect changes found to be desirable that could not be accomplished by executive action alone. President Taft caused a commission to be organized, and as a result of its studies, sent to Congress four special messages transmitting the reports of the commission, dealing with particular subjects, pointing out defects in the organization and conduct of the business and changes that might be made advantageously.

Federal Budget Urged.—In his message of Jan. 17, 1912, the president called attention to the fact that the United States was the only great nation whose Government was operated without a budget, and recommended the adoption of an annual budget. Nothing was done by Congress in these matters, but many, if not most, of the improvements in the organization and conduct of the administrative branch of the Government which have been adopted in more recent years were first formulated and recommended by President Taft. He also recommended to Congress the enactment of amendments to the interstate commerce law, the establishment of a postal savings bank system, the enactment of laws giving the interstate commerce commission the power to determine upon the uniform construction of appliances used by railway trainmen in the operation of trains and to intervene and investigate the reasonableness of a proposed increase in railway rates before they became effective; of amendments making the Employer's Liability Act more easy to enforce; of laws carrying out with intelligent discrimination the principle of conserving the national resources; the establishment of a national health bureau; requiring publicity of campaign contributions; regulating the procedure of Federal courts concerning the issue of injunctions; and readjusting the regulations concerning postage of second class mail matter. Most of these recommendations were embodied in laws passed by the Congress. By executive order, the President placed the positions of secretaries in the diplomatic service in much the same position as those in the consular service, and introduced into both the principle of appointment for reasons of ascertained fitness and promotion by merit.

Arbitration Treaties.—In 1910 and 1911, President Taft negotiated with the Governments of France and Great Britain identical treaties, signed on Aug. 3, 1913, intended to be models for a series of treaties providing firstly, for the arbitration of all differences which might arise between the parties which it was not possible to adjust by diplomacy, and which were justiciable in their nature, and secondly, for the creation of a joint high commission of inquiry, to which should be referred for impartial investigation, any justiciable controversy between the parties before submission to arbitration, and also any other controversy, even if the parties were not agreed that it fell within the scope of the first article; the report of such commission not to be regarded as a decision on the questions submitted. The first of these provisions embodied in effect the agreement reached in the treaty between the United States and France of Feb. 6, 1928. The second furnished a model for the treaties negotiated by Secretary Bryan in 1914, known as the Bryan Conciliation Treaties. Together, they represented a greater advance in provisions for the peaceful settlement of international controversy than any the world had known. The U.S. Senate qualified its approval by such extensive reservations, that the president withdrew the treaties from further consideration. In 1910, President Taft initiated negotiations with the British Government for the establishment of a reciprocal trade agreement between the United States and the Dominion of Canada. Instead of embodying the desired tariff changes in the formal shape of a treaty, it was agreed that the Governments of the two countries should use their utmost efforts to bring about such changes by concurrent legislation at Washington and Ottawa. It was further agreed that a considerable list of articles produced in both countries should be reciprocally free. As to another group, common rates of duties upon importation from either country into the other were fixed. The proposed legislation was, however, defeated in the dominion parliament, and the effort failed.

As the construction of the Panama canal approached completion, a bill was introduced in Congress to provide for its operation and for the government of the Canal Zone. Taft was of the opinion that as the United States had built the canal at its own

expense, it was entitled to permit the use of the canal by American merchant ships without payment of tolls. Great Britain claimed that this would be a violation of the Hay-Pauncefote Treaty. While not admitting the contention, the president expressed his willingness to arbitrate the question. The bill, as passed, embodied the president's views, but the next Congress modified the act by removing the discrimination.

Other Events in Administration.—President Taft's administration was characterized by a systematic and vigorous enforcement of the antitrust laws. The decisions by the U.S. Supreme Court in 1911, of the prosecutions which had been initiated by Pres. Theodore Roosevelt against the Standard Oil trust and the American Tobacco combination, and which were argued in the Supreme Court by Atty. Gen. George Wickersham, gave an authoritative interpretation to the act, which was at once put into effect by the Department of Justice, and for the first time after the enactment of the law in 1890, a careful, systematic effort was made by the Government to enforce its provisions. Both the oil trust and the tobacco combination were dissolved in such manner as to restore healthy competition in those industries without destruction of the value of their securities held by innocent parties. A large number of combinations in restraint of trade were either put an end to by judicial process, or voluntarily desisted from a continuance of the practices which had been adjudged to be illegal.

During Taft's administration, many vacancies occurred in the Federal judiciary. He was called upon to appoint six justices of the Supreme Court, including a chief justice. On the death of Chief Justice Fuller, in 1910, President Taft nominated as his successor, Associate Justice Edward D. White, a Democrat, a former Confederate soldier, and a Roman Catholic—a nomination which was confirmed by the Senate at once.

Conservation of the natural resources of the nation was one of the subjects which had greatly occupied the attention of the president and his administration. While Taft was in full sympathy with the objects of this policy, he did not approve of some of the means adopted by that administration. In making up his cabinet, he did not include James R. Garfield, secretary of the interior under President Roosevelt, and on Jan. 7, 1910, he dispensed with the services of Gifford Pinchot, the forester. These men, with a number of other adherents of Roosevelt, initiated a campaign against President Taft, based upon the representation that he was opposed to the conservation policy of Roosevelt. Their first attack upon his Administration was directed against Richard Ballinger, who had succeeded Garfield as secretary of the interior. A complaint by L. R. Glavis, an agent in the land office in the department of the interior, of Ballinger's action with regard to certain coal land entries in Alaska known as the Cunningham claims, which President Taft on investigation held to be unfounded, and which led to the dismissal of Glavis from the service, gave rise to a Congressional investigation into the conduct of the interior department by Ballinger. After prolonged hearings a report was made by the committee exonerating Ballinger, but failing to win the confidence of the public, he resigned in the spring of 1911.

In the regular Republican convention at Chicago, Ill., the total number of delegates summoned was 1,078, with 540 necessary to a choice. Taft had 561 votes on the first and only ballot and was declared the nominee. Roosevelt and his progressive supporters, claiming that part of his delegates had been stolen through the action of a hostile committee, refused to accept the results of the convention, organized one of their own, known as the "Bull Moose" convention, nominated Roosevelt for the presidency and carried on an aggresive campaign against Taft, which resulted in splitting the Republican vote in almost every State, and thus electing Woodrow Wilson, the Democratic nominee, as president. The electoral vote was: for Wilson, 435, Roosevelt, 88 and Taft, 8. The popular vote, however (Wilson, 6,285,214; Roosevelt, 4,126,020; Taft, 3,483,922), showed a much closer contest. This Party schism served in large measure to obscure the merits of President Taft's administration.

Subsequent Career.—On retiring from the presidency in 1913, Taft became Kent professor of law at Yale, but devoted much time to lecture engagements. In the same year he was elected president of the American Bar association, and in 1914 first president of the American Institute of Jurisprudence, organized to improve law and its administration. Taft was an active promoter of the League to Enforce Peace, but after U.S. entrance into World War I, he supported the Administration, taking the ground that victory was necessary to the attainment of lasting peace. In 1918, he was appointed by President Wilson a member of the national war labour board for arbitrating labour disputes. In 1919, he endorsed the peace treaty of Versailles, regarding its most important part to be the Covenant of the League of Nations. He spoke throughout the country on behalf of the League urging reservations if these would secure ratification. On the death of Chief Justice Edward White, on June 30, 1921, he was appointed chief justice by Pres. Warren G. Harding. He died in Washington on March 8, 1930.

In 1886 he had married Helen Herron (1861–1943).

Taft is the author of *Popular Government; Its Essence, Its Performance, and Its Perils* (1913); *The Anti-Trust Act and the Supreme Court* (1914); *The United States and Peace* (1914); *Ethics in Service,* Yale lectures (1915); *Our Chief Magistrate and His Powers,* Columbia lectures (1916) and *The Presidency: Its Duties, Its Powers, Its Opportunities and Its Limitations,* lectures at the University of Virginia (1916). (G. W. Wi.)

TAGALOG, the second largest ethno-linguistic group in the Philippines, inhabiting central and southern Luzon and numbering, in 1948, 3,730,028; they are considered the most cultured and westernized Filipino, a pre-eminence resulting largely from their proximity to Manila, the great city of the Philippines which was the focal point of more than 300 years of Spanish contact and a half-century of American influence. Literacy among the Tagalogs in either English or the vernacular is the highest in the Philippines, exceeding 70%. A majority of the national leaders in all fields have come from this group. In 1940 Tagalog became the basis for the Philippine national language and by 1948, persons able to speak Tagalog numbered 7,126,913.

The Tagalogs are primarily rural agriculturists, rice and coconuts being the major crops, and they generally live in barrios (small villages) of from 100 to 700 persons. Nevertheless, many Tagalogs are found in the urban centres, providing a professional and business class.

At least 83% of the people in the Tagalog area are Roman Catholics; the remainder are affiliated with the Philippine Independent Church (about 7%), with one of a number of Protestant churches or evangelical groups (total about 3%) or with some other religious body. The elementary family and the sibling group are the basic units of their social organization and these have marked solidarity as reflected in the Philippine Civil Code. Life in the characteristic rural areas is highly co-operative, being based upon primary group relationships and a system of reciprocal obligations. (R. B. Fx.)

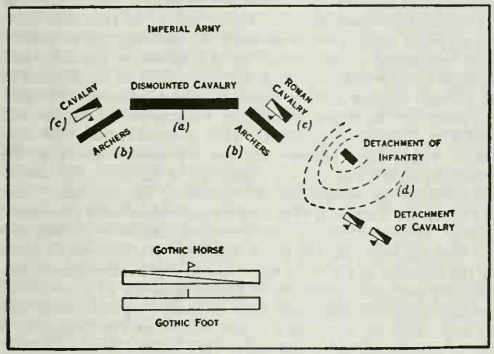
TAGANROG, a Russian seaport in the Rostov *oblast,* Russian Soviet Federated Socialist Republic, U.S.S.R., on the north shore of the northeastern arm of the Sea of Azov. Pop. (1956 est.) 189,000. It is connected by rail with the north, and also with Rostov-on-Don to the east. A colony was founded on the site by Pisan merchants in the 13th century, but was destroyed by the Mongols. Later it was occupied by the Turks and annexed to Russia in 1769.

TAGES, a minor Etruscan deity, the grandson of Jupiter and founder of the art of divination in Etruria. According to the story, during the plowing of a field near Tarquinii a being of boyish appearance sprang out of the furrow. The shouts of the plowman (Tarchon) brought a crowd to the spot and later all the people of Etruria, whom the boy proceeded to instruct in the art of divination. Having done this, he suddenly disappeared. His instructions were committed to writing and formed the 12 books of Tages, containing a complete system of Etruscan lore.

TAGINAE, BATTLE OF (A.D. 552). The battle of Taginae was fought in July 552. It terminated the Gothic Wars of the Emperor Justinian, and was won over the Gothic King

Baduila by the eunuch Narses, a general who in ability rivalled the great Belisarius, his contemporary. Taginae is situated below the Apennines near modern Gubbio. Narses had crossed the head of the valley of the Chiascio when Baduila arrived and seized its main outlet. The Goth ranged the whole of his horsemen in front, his infantry, mostly archers, he drew up in second line. His aim was to ride down the imperial army in one terrific charge.

Belisarius had noted the weakness in the Gothic tactics, namely, that there was no co-operation between lance and bow. Narses



BATTLE OF TAGINAE (JULY, A.D. 552), WON BY NARSES, GENERAL OF THE EMPEROR JUSTINIAN, OVER BADUILA, KING OF THE GOTHS

now aimed at this co-operation, but in a novel form which closely resembles the combined tactics made use of by Edward III. at Crécy. He dismounted his cavalry (*Foederati*) and formed a phalanx 8,000 strong, on the wings of which he drew up 8,000 archers with their outer flanks thrown forward. In rear of these he posted his Roman cavalry to combine fire and shock. His left flank he rested on a small hill, which he occupied by a force of infantry and at the foot of which he deployed a few squadrons of cavalry.

At noon Baduila, ignoring the archers, suddenly charged his enemy's centre, expecting to overwhelm it, for infantry he held in contempt. He was met by a tremendous converging fire of arrows which slew and dismounted hundreds of his knights. After several assaults he clinched with the imperial centre—its protective base of action—which held him firm whilst his flanks were plied with arrows. At length, exhausted, the Gothic horsemen broke back, when immediately Narses launched his mounted squadrons driving them in confusion on to their infantry which were ridden over. The victory was complete.

TAGLIACOZZO, a town of Abruzzi e Molise, Italy, in the province of L'Aquila, 56 mi. by rail E.N.E. of Rome and 10 mi. W. of Avezzano. Pop. (1951) 3,903. It lies 2,428 ft. above sea level, at the mouth of the deep ravine of the Imele. It contains several old churches, notably S. Francesco, with a fine rose window in the façade, and medieval houses.

The palace, built at the end of the 14th century by the Orsini, is fine, with interesting paintings in the interior. At the end of 1268 a battle took place here between Conradin of Hohenstaufen and Charles of Anjou, which resulted in the defeat of Conradin.

Tagliacozzo is a resort and has felt and hosiery mills.

TAGORE, SIR RABINDRANATH (1861–1941), Indian poet and author, was born in Calcutta on May 6, 1861, the youngest son of Maharshi Devendranath and grandson of Prince Dwarkanath Tagore. After a private education in India he was sent to England in 1877 to study law, but soon returned to India, and while still quite young commenced writing for Bengali periodicals. In 1901 he established the famous Santiniketan, a school at Bolpur, 93 mi. from Calcutta, which developed into an important educational institution conducted on unconventional lines. In 1913 Tagore was awarded the Nobel prize for literature, and utilized the amount, £8,000, for the up-keep of his school. He visited Europe on several occasions and travelled also in Japan and the United States. He accepted a knighthood in 1915, but in 1919 resigned it as a protest against the methods adopted for the repression of disturbances in the Punjab. In later years, however, he offered no objection to the use of this title. Tagore was interested in politics only in so far as it concerned the deeper life of India, and he desired that the nationalist movement consider social reforms before political freedom. By his abundant writings, which are permeated by a sense of the beauty of the universe, by a love of children and of simplicity, and by a consciousness of God, Tagore did much to interpret for the west the more serious reflections of the people of Bengal. In 1929 he took up painting. He died Aug. 7, 1941.

His most important works which have been translated into English are *Gitanjali* (1913); *The Crescent Moon* (1913); *Chitra* (1914); *The Post-Office* (1914); *The Gardener* (1914); *One Hundred Poems of Kabir* (1915); *Fruit-Gathering* (1916); *Stray Birds* (1916); *Nationalism* (1917); *My Reminiscences* (1917); *The Parrot's Training* (1918); *The Home and the World* (1919); *Red Oleander* (1924); *Broken Ties* (1925); *Letters to a Friend* (1928); *The Religion of Man* (1931). *See* E. Thompson: *R. Tagore, Poet and Dramatist* (Oxford, 1926).

TAGUS, the second longest river of the Iberian peninsula. Its length is 565 mi., of which 171 are on or within the frontier of Portugal, and the area of its basin is 31,213 sq.mi. The basin is comparatively narrow, and the Tagus, like the other rivers of the Iberian tableland, generally flows in a rather confined valley, often at the bottom of a rocky gorge, as at Toledo and Alcántara, below the general level of the adjacent country. The river rises on the western slope of the Muela de San Juan (5,312 ft.), a mountain which forms part of the Sierra de Albarracin, 88 mi. E. of Madrid. Thence the Tagus flows at first north-westwards, but, after receiving the Gallo on the right, it flows west, and then south-west or west-south-west, which is its general direction for the rest of its course. Regular river navigation begins only at Abrantes, a few miles below which the Tagus is greatly widened by receiving on its right bank the impetuous Zezere from the Serra da Estrella. Passing Santarem, the highest point to which the tide ascends, and the limit of navigation for large sailing vessels and steamers, the river divides below Salvaterra into two arms which enclose a deltaic formation, a low tract of marshy alluvium known as the Lezirias, traversed by several minor channels. Both branches terminate in a broad tidal lake immediately above Lisbon (*q.v.*). The Tagus estuary, though partly blocked by a bar of sand, is one of the chief harbours of south-western Europe.

TAHITI, the largest and most important of the Society Islands (part of French Polynesia) in the central South Pacific ocean. The island lies in lat. 17° 38′ S. and long. 149° 25′ W. It is 33 mi. long, northwest to southeast, and consists of the deeply dissected cones of two ancient volcanoes joined by a narrow isthmus of low land, the whole fringed by a coral barrier reef lying from 1 to 2 mi. offshore. The northern cone is roughly circular in plan, about 20 mi. across and rises to a height of 7,339 ft. Numerous secondary cones rise from its ravined sides and there is a narrow plain encircling the base. To the southeast and joined to the larger cone by an isthmus about ¾ mi. wide, the second cone rises to a height of 4,341 ft. The oval-shaped peninsula of Taiarapu has a northwest-southeast length of 14 mi. and a breadth of 8 mi. For a further account of its physical features, *see* PACIFIC ISLANDS.

Tahiti has an area of 388 sq.mi. and a population (1956) of 36,326. The chief town and seat of the French administration is Papeete at the northwestern end of the island. Its commune population in 1956 was 17,247. All the inhabitants are French citizens (1,000 of metropolitan origin) except for the Chinese (5,242) and some other foreigners (300).

The island produces coconuts, bananas, sugar cane and other tropical plants. The chief export is copra of which 21,570 tons were exported in 1954.

History.—Tahiti seems to have been peopled in about the 14th century by Polynesians from the neighbouring island of Raiatéa. The first European to visit it was the Englishman Samuel Wallis (1767). Then came the Frenchman L. A. de Bougainville (1768) and the Englishman James Cook (*q.v.*; 1769, 1773 and 1777). The first English missionaries landed in 1796 but they were unsuccessful. Interisland wars were mainly responsible for the failures though the attempts were favoured by the support of the local rulers, Pomare I and Pomare II. The latter fled with the missionaries in 1808, but returned with them in 1812, having renounced heathenism, and regained his power in 1815. For a time missionaries made good progress—a printing press was established (1817), and coffee, cotton and sugar were planted (1819); but soon there came a serious relapse.

Pomare II died in 1824. His successor, Pomare III, died in 1827, and was succeeded by his half-sister Aimata, called Queen Pomare IV.

In 1836 French Catholics attempted to open a mission in Tahiti. Queen Pomare, advised by the English missionary and consul, George Pritchard, removed by force two priests who had landed surreptitiously. In 1842 a French frigate appeared under the command of Abel Dupetit-Thouars, and obtained from Pomare the right of settlement for Frenchmen. Pritchard opposed this, and caused Pomare to apply for British protection; but this was a failure, and the native chiefs compelled the queen to turn to France.

A convention was signed in 1843, placing the islands under French protection. Dupetit-Thouars now reappeared, and, alleging that the treaty had not been duly carried out, deposed the queen and took possession of the island. His highhanded action was not countenanced by the French government and the protectorate was re-established. Trouble broke out and it was only in 1846 that the queen, who had taken refuge in the Windward Islands, regained Tahiti.

Queen Pomare died in 1877, and her son Ariane (Pomare V) abdicated in 1880. In the same year Tahiti was proclaimed a French colony and became the centre of French Oceania.

Tahiti, with the other Society Islands, adhered to the "Free French" movement of Gen. Charles de Gaulle during the German occupation of France, 1940–44. In 1946 all the inhabitants became French citizens.

TAHR (*Hemitragus jemlaicus*), a shaggy-haired, brown Himalayan wild goat, characterized by its short, triangular and sharply keeled horns. Besides the tahr the genus includes the wariatu or Nilgiri ibex (*H. hylocrius*), from south India, and the smaller *H. jayakeri*, from south Arabia. Tahr frequent the worst ground of all ruminants.

TAILLE, the equivalent of the English *tallage* (*q.v.*), was in France the typical direct tax of the middle ages, just as the word *tonlieu* was the generic term for an indirect tax. Other words used in certain districts in the same sense as *taille* were *queste* (*questa, quista*), *fouage* (*foragium*), *cote*. The essence of the tax denoted by these names was that the amount was fixed *en bloc* for a whole group of persons, and afterwards divided among them in various ways. In ancient French law we find three forms of *taille:* the *taille servile, taille seigneuriale* and *taille royale*.

The *taille servile* can scarcely be termed a tax; it was rather a tax which had degenerated into a source of profit for certain individuals. Every lord who possessed serfs could levy the *taille* on them, and originally this was done arbitrarily (*a volonté*) both as to frequency and amount. It always remained a characteristic feature of serfdom, but was limited and fixed, either by contracts or concessions from the lord (*taille abonnée*), or by the customs.

The *taille seigneuriale* was a true tax, levied by a lord on all his subjects who were neither nobles nor ecclesiastics; but the writer holds that, when feudalism was set up, the right to levy it did not belong to every lord, but only to the lord having the *haute justice*. But he levied it by right, without the necessity for any contract between him and those who paid it. He fixed the sum to be paid by each group of inhabitants, who then had to see that it was assessed, collected and paid to the lord, electing commissaries (*preud hommes*) from among themselves for this purpose. The seigniorial *taille*, like the servile, had the character of a personal tax (*taille personelle*), a rudimentary tax on income, every man being taxed according to his wages or other income. The king originally had only the right of levying the *taille* in places where he had retained the exercise of the *haute justice*. At that time there was no royal *taille*, strictly speaking; it was only the seigniorial *taille* transferred to the Crown, but it was one of the first taxes his right to levy which upon all the inhabitants of the domain of the Crown, whether serfs or *roturiers*, was recognized. The general *taille*, for the benefit of the king, became more frequent, and tended to become permanent. This transformation was confirmed, rather than effected, by the *ordonnance* of 1439. Its immediate object was, not the regulation of the *taille*, but the organization of the *compagnies d'ordonnance, i.e.*, the heavy cavalry which the king from that time on maintained on a permanent footing. Military expenses thus becoming permanent, it was natural that the *taille*, the tax which had long been devoted to meeting the expenses of the royal wars, should also become permanent. This was contained implicitly in the *ordonnance* of 1439, which also suppressed the seigniorial *taille*, as competing too closely with the royal *taille* by imposing a double burden on the taxpayer. A kind of seigniorial *taille* continued to exist besides the servile *taille*, but this kind presupposed a title, a contract between the taxable *roturier* and the lord, or else immemorial possession, which amounted to a title.

Throughout the *pays d'élections* the *taille* was almost universally personal (*taille personnelle*); *i.e.*, a tax on the whole income of the taxpayer, whatever its source. It was also a distributory tax (*impôt de repartition*); every year the king in his council fixed the total sum which the *taille* was to produce in the following year; he drew up and signed the *brevet de la taille* (warrant), and the contribution of the individual taxpayer was arrived at in the last analysis by a series of subdivisions.

In certain districts the *taille* was real (*taille reelle*); *i.e.*, a tax on real property. It was not an equal tax falling on all landowners, but the question as to whether a certain estate was to be taxed or not was decided according to the quality of the property, and not that of the owner. The *biens nobles* (*fiefs*) and the *biens ecclesiastiques* were exempt; *tenures roturières*, however, by whomsoever held, were taxed. A small part of the *pays d'élections* was also *pays de taille réele*. But it was the chief form of tax in the *pays d'états*, and even there an attempt had generally been made to check the exemption of nobles' property. It has been shown that in these districts the *taille* had originally been personal, having become real by a curious evolution. In these districts there were *cadastres*, or *compoix-terriers* (land registers), which allowed of a non-arbitrary assessment; and at the end of the *ancien régime* merely needed revision.

In certain provinces where the royal *taille* was levied there were neither *élections* nor *généralités*, and the whole administration of the tax was in the hands of the *intendants*. These were the provinces of the east and north, which were united to the Crown at a period when the power of the *intendants* was already fully developed; they were sometimes known as *pays d'imposition*.

See Auger, *Code des tailles* (1788); Henri Sée, *Les Classes rurales et le régime domanial en France au Moyen Âge* (1901).

(J. P. E.; X.)

TAILLEFER, the surname of a bard and warrior of the 11th century, whose exact name and place of birth are unknown. He accompanied the Norman army to England in 1066, and obtained permission from William to strike the first blow at the battle of Hastings, where he was killed. Mention of Taillefer is made by Guido, bishop of Amiens, in his *Carmen de bello Hastingensi*, v. 931–944 (in *Mon. Hist. Brit.*, 1848) and by Henry of Huntingdon in his *Historia Anglorum* (in *Rer. Brit. med. aevi script.*, p.

763, ed., Arnold, London, 1879); and his prowess is depicted on the Bayeux tapestry. The statement of Wace in the *Roman de Rou*, 3rd part, v. 8035–62, ed. Andresen (Heilbronn, 1879), that Taillefer went before the Norman army singing of Charlemagne and of Roland and the vassals who died at Roncevaux, has been considered important in demonstrating the existence of a comparatively early tradition and song of Roland.

See W. Spatz, *Die Schlacht von Hastings* (Berlin, 1896); Freeman, *History of the Norman Conquest*.

TAILOR, one who cuts out and makes clothes (Fr. *tailleur*, from *tailler*, to cut, Lat. *talea*, a thin rod, a cutting for planting). Formerly the tailor, or *cissor*, made apparel for both men and women, and not merely outer garments, but also articles of linen and the padding and lining of armour—whence the style "Taylors and Linen Armourers" applied to the Merchant Taylors Company of the City of London in their earliest charters. But the word is now generally limited to those who make the outer (cloth) garments for men, and less frequently for women, though a phrase such as "shirt-tailor" is occasionally met with. In modern usage, too, it commonly has the implication that the garments are made to the order, and to the measure, of the individual purchaser, as opposed to ready-made clothing, which means articles of apparel manufactured in large quantities in a series of stock or standard sizes, such that any purchaser may expect to find among them one that will fit him with more or less accuracy. The clothing trade was originally confined to goods of the poorest grades, but it has come, both in Great Britain and in America, to include articles of good, though not of the first, quality. It probably first came into existence at seaport towns, where, to meet the convenience of sailors returning from long voyages and requiring their wardrobes to be replenished at short notice, the "outfitters" kept stocks of ready-made garments on sale; but it made no considerable progress until after the middle of the 19th century, when the introduction of the sewing-machine brought about the possibility of manufacturing in large quantities. Its development was attended with gradually increasing subdivision of labour and, to a large extent, with the disappearance of the tailor as a skilled craftsman.

The first step was for a garment, such as a coat, to be completed by the joint efforts of a family. Then followed the "task system," which in America was the result of the influx of Russian Jews that began about 1875. Under it a team of three men, with a "presser" and a girl to sew on the buttons, divided the work between them. Payment was made by the "task," *i.e.*, a specified number of garments, the money being divided between the members of the team in certain proportions. Often several teams would be run by a contractor, who naturally selected the cheapest workshops he could find and packed them as full of workers as possible; and when through stress of competition he had to accept lower prices the plan he adopted was to increase the number of garments to a task, leaving the pay unaltered. The result was the introduction of many of the worst features of the "sweating system," the workers having to work excessively long hours in order to finish the task, which in some cases meant as many as 20 coats a day. In the "factory" or "Boston" system the subdivision is still more minute, and as many as 100 persons may be concerned in the production of one coat. The amount of tailoring skill required in a worker is even further reduced, but the premises come under the regulation of the factory laws. The factory system has also cheapened production in a legitimate way, because it has enabled mechanical power for driving sewing-machines, and also expensive labour-saving machinery, to be introduced to an extent not practicable in small shops.

TAIN, a royal and small burgh in the county of Ross and Cromarty, Scot., near the southern shore of Dornoch firth, 26½ mi. N.E. of Dingwall by road. Pop. (1961) 1,699. The name is from the Icelandic *thing* (assembly). It is the centre of a prosperous agricultural area specializing in raising and exporting seed potatoes (mainly to England) and in rearing the valuable Calrossie shorthorn cattle. There are well-known golf links. Anciently Tain was a place of sanctuary, the "Immunity of Tayne" being marked by four crosses, but the privilege was violated in 1306, when the earl of Ross abducted Robert Bruce's wife and daughter and handed them over to Edward I, and again in 1427 when McNeille of Creich burned the chapel of St. Duthac (Duthus) of which there are remains near the railway station. The church of St. Duthus was built by the bishop of Ross in 1370. In 1487 it became collegiate, the alteration being confirmed by a papal bull still preserved by the corporation. The building was used as the parish church until 1815 when it fell into disrepair, but it was restored in 1871–76. Three and a half miles southeast are the remains of the abbey of Fearn, founded at Edderton in 1230 by Farquhar, 1st earl of Ross, and transferred thither in 1338.

TAINE, HIPPOLYTE ADOLPHE (1828–1893), French critic and historian, son of Jean Baptiste Taine, an attorney, was born at Vouziers on April 21, 1828. J. B. Taine died on Sept. 8, 1840, leaving a moderate competence to his widow, his two daughters, and his son. Taine was educated at the Collège Bourbon, where he formed lifelong friendships with L. A. Prévost-Paradol, long his most intimate friend, Émile Planat, the future "Marcelin" of the *Vie parisienne*, and Cornélis de Witt, who introduced him to Guizot when the latter returned from England in 1846. Taine passed from the Collège Bourbon to the École Normale, but in 1851 he was refused the fellowship in philosophy which was universally regarded as his due. Nevertheless the minister of public instruction appointed him to a professorship at Toulon, which he exchanged for one at Nevers. But he refused to express explicit approval of the coup d'état of Dec. 2, 1851. Consequently he was removed to an inferior post; next year saw a further step downward, and he accordingly applied for, and received, indefinite leave of absence. In a few months his two dissertations, *De personis Platonicis* and the essay on La Fontaine's fables were finished, and May 30, 1853 he took his doctor's degree. This was the last act of his university career; his life as a man of letters was to begin.

No sooner had he deposited his dissertations at the Sorbonne than he began to write an essay on Livy for one of the competitions set by the academy. There again the moral tendency of his work excited lively opposition, and after much discussion the competition was postponed till 1855; Taine toned down some of the censured passages, and the work was crowned by the academy in 1855. In the beginning of 1854 Taine, after six years of uninterrupted effort, broke down and was obliged to rest. The year 1854 was an important one in the life of Taine. His enforced leisure, the necessity of mixing with his fellowmen, and of travelling, tore him from his cloistered existence and brought him into more direct contact with reality. He lived with his mother in the Ile Saint-Louis and once more associated with his old friends, Planat, Prévost-Paradol and Edmond About. He made the acquaintance of Renan, and through Renan that of Sainte-Beuve, and he renewed friendly relations with Ernest Havet, who for three months had been his teacher at the École Normale. These years (1855–56) were Taine's periods of greatest activity and happiness in production. In 1855 he published 17 articles in the *Revue de l'instruction publique*, and 20 in 1856 on the most diverse subjects, ranging from Menander to Macaulay. From 1857 onward he was a regular contributor to the *Journal des débats*.

But he was seeking a larger field. In Jan. 1856 his history of English literature was announced, and in 1855–56 he published in the *Revue de l'instruction publique* a series of articles on the French philosophers of the 19th century, which appeared in a volume at the beginning of 1857. In this volume he energetically attacked the principles which underlie the philosophy of Victor Cousin and his school. The book closes with the sketch of a system in which the methods of the exact sciences are applied to psychological and metaphysical research. The work itself met with instantaneous success, and Taine became famous. In 1858 appeared a volume of *Essais de critique et d'histoire;* in 1860 *La Fontaine et ses fables*, and a second edition of the *Philosophes français*.

In 1864 Taine succeeded Viollet-le-Duc as professor of the history of art and aesthetics at the École des Beaux Arts. Renan's appointment at the Collège de France and Taine's candidature for the Polytechnic school had alarmed Dupanloup, who in 1863 issued an *Avertissement à la jeunesse et aux pères de famille*, which consisted of a violent attack upon Taine, Renan and Littré.

Renan was suspended, and Taine's appointment to Saint Cyr would have been cancelled but for the intervention of the princess Mathilde. In Dec. 1863 his *Histoire de la littérature anglaise* was published, prefaced by an introduction in which Taine's determinist views were developed in the most uncompromising fashion. In 1864 Taine sent this work to the academy to compete for the Prix Bordin. M. de Falloux and Dupanloup attacked Taine with violence; he was warmly defended by Guizot; finally, after three days of discussion, it was decided that as the prize could not be awarded to Taine, it should not be awarded at all. After three attempts to secure admission to the academy Taine was elected in Nov. 1878.

The period from 1864 to 1870 was perhaps the happiest of Taine's life. He derived pleasure from his employment at the Beaux Arts and Saint Cyr, which left ample leisure for travel and research. In 1865 appeared *La Philosophie de l'art*, in 1867 *L'Idéal dans l'art*, followed by essays on the philosophy of art in the Netherlands (1868), in Greece (1869), all of which short works were republished later (1880) as a work on the philosophy of art. In 1865 he published his *Nouveaux essais de critique et d'histoire;* from 1863 to 1865 appeared in *La Vie parisienne* the notes he had taken for the past two years on Paris and on French society under the subtitle of "Vie et opinions de Thomas Frédéric Graindorge," published in a volume in 1867, the most personal of his books, and an epitome of his ideas. In 1867 appeared a supplementary volume to his history of English literature, and in January 1870 his *Théorie de l'intelligence*. In 1868 he married Mademoiselle Denuelle, the daughter of a distinguished architect. He had made a long stay in England in 1858, and had brought back copious notes, which, after a second journey in 1871, he published in 1872 under the title of *Notes sur l'Angleterre*.

Taine, deeply shaken by the events of 1870, felt that it was the duty of every Frenchman to work solely in the interests of France. On Oct. 9, 1870 he published an article on "L'Opinion en Allemagne et les conditions de la paix," and in 1871 a pamphlet on *Le Suffrage universel;* and his intention of writing on the French Revolution returned in a new and definite shape. He determined to trace in the Revolution of 1789 the reason of the political instability from which modern France was suffering. From the autumn of 1871 to the end of his life his great work, *Les Origines de la France contemporaine*, occupied all his time, and in 1884 he gave up his professorship in order to devote himself wholly to his task; but he succumbed before it was finished, dying in Paris on March 9, 1893.

Les Origines de la France contemporaine, Taine's monumental achievement, stands apart from the rest of his work. The problem which Taine set himself was to inquire why the centralization of modern France is so great that all individual initiative is practically nonexistent, and why the central power, whether it be in the hands of a man or of an assembly, is the sole and only power; also to expose the error underlying two prevalent ideas. Against the view that the Revolution destroyed absolutism and set up liberty, he points out that it merely caused absolutism to change hands. Opposing the view that the Revolution destroyed liberty instead of establishing it or that France was less centralized before 1789 than after 1800 he retorts that France was already a centralized country before 1789 and grew rapidly more and more so from the time of Louis XIV onward: the Revolution merely gave it a new form. The *Origines* differ from the rest of Taine's work in that, although he applies to a period of history the method which he had already applied to literature and to the arts, he is unable to approach his subject in the same spirit. He loses his philosophic calm, he cannot help writing as a man and a Frenchman, he lets his feeling have play, and what the work loses thus in impartiality it gains in life.

Taine was the philosopher of the epoch which succeeded the era of romanticism (1820–50) in France. The ideal of the newer generation was truth; their watchword liberty; to get as near as possible to scientific truth became their object. Taine must ever be regarded as one of the most authoritative spokesmen of this period.

Taine served science unfalteringly, without looking forward to any possible fruits or result. In his work we find neither enthusiasm nor bitterness, neither hope nor yet despair; merely a hopeless resignation. The study of mankind was Taine's incessant preoccupation, and he followed the method already described. He made a searching investigation into humanity and his verdict was one of unqualified condemnation. In "Thomas Graindorge" we see him aghast at the spectacle of man's brutality and woman's folly. In man he sees the primeval savage, the gorilla, the carnivorous and lascivious animal, or else the maniac with diseased body and disordered mind, to whom health, either of mind or body, is but an accident. Taine is appalled by the *bête humaine;* and in all his works we are conscious, as with Swift and Voltaire, of the terror with which the possibilities of human folly inspire him. It may be doubted whether Taine's system, to which he attached so much importance, is really the most lasting part of his work. For Taine was an artist as well as a logician, an artist who saw and depicted what he saw in vital and glowing language. From the artist we get his essay on La Fontaine, his articles on Balzac and Racine, and the passages on Voltaire and Rousseau in the *Ancien Régime*. Moreover, not only was Taine an artist who had not escaped from the influence of the romantic tradition, but he was by his very method and style a romanticist. His emotions were deep if not violent, his vision at times almost lurid. He sees everything in startling relief and sometimes in exaggerated outline, as did Balzac and Victor Hugo. Hence his predilection for exuberance, strength and splendour; his love of Shakespeare, Titian and Rubens; his delight in bold, highly-coloured themes.

Taine's influence was great, and twofold. On his own generation it was considerable; during the epoch in which he lived, while a wave of pessimism was sweeping over French literature, he was the high priest of the cult of misanthropy, in which even science was held to be but an idol, worthy of respect and devotional service, but not of faith. In its turn came the reaction against positivism and pessimism, and an attempt at spiritual renascence. Around a man so remarkable as Taine a school was certain to form itself; Taine's school, which was one of positivist doctrines, rigid systems and resigned hopelessness, was equally certain to produce at some time or another a school of determined opponents to its doctrines and system. If, therefore, the tone which pervades the works of Zola, Bourget and Maupassant can be immediately attributed to the influence that we call Taine's, it is also the influence of Taine which is one of the ultimate causes of the protest embodied in the subsequent reaction. (M. Bg.; X.)

BIBLIOGRAPHY.—The official life, *H. Taine, sa vie et sa correspondance*, was published in 3 vol. (1902–05), Eng. trans. by Mrs. R. L. Devonshire (1902–08). His friend, Émile Boutmy, published an appreciative study of Taine's philosophy in his *Taine, Scherer, Laboulaye* (Paris, 1901). *See* also Émile Faguet, *Politiques moralistes au XIX^e siècle* (Paris, 1900); M. Barrès, *Taine et Renan* (1922); F. C. Roe, *Taine et l'Angleterre* (1923); A. Chevrillon, *Taine, formation de sa pensée* (1932).

T'AI-PEI (Japanese, TAIHOKU), one of the chief cities of Formosa (Taiwan). Founded in 1708, T'ai-pei after the middle of the 19th century became an important centre for overseas trade through its outport, Tan-shui. This trade was based upon tea and was dominated by British trading companies.

Situated in the centre of the largest agricultural basin in northern Formosa, T'ai-pei (population in 1956 was 668,093 exclusive of rural areas included in the T'ai-pei city administrative district) forms the nucleus of a major industrial area. The T'ai-pei industrial complex includes light and heavy industries within the urbanized area and also in several industrial suburbs, including Pan-ch'iao and Nan-chiang. Cotton and artificial fibre textiles, rubber goods, electrical appliances, alcoholic beverages, metal products, chemicals, coke and printed materials are produced. T'ai-pei also is the island's major communications centre, containing the central workshops of the government owned railway and Formosa's international airport. National Taiwan university and the Taiwan Provincial Normal university, as well as several professional and specialized training schools, are located in T'ai-pei. Because it contains more mainland Chinese than any other Formosan city, characteristic types of mainland entertainment, such as opera and fine regional restaurants, are found there.

Under Japanese rule (1895–1945) T'ai-pei was the seat of the Taiwan government-general; as a result it acquired the characteristics of an administrative centre, such as public buildings and extensive civil servant housing facilities. After the communists took China in 1949, it became the capital-in-exile of the Nationalist government of the Republic of China, headed by Chiang Kai-shek. (N. S. G.)

T'AI P'ING REBELLION. The T'ai P'ing rebellion of 1851–1864 in China was a great national religious-political upheaval. It inspired many other rebellions and revolutions in late 19th-century China, culminating in Sun Yat-sen's overthrow of the Manchu dynasty in 1911–12. Historical judgment of it has varied. The rebellion has been condemned as the work of "Cantonese bandits" or "long-haired bandits," and has been praised as a national agrarian and proletarian revolution. This great upheaval grew out of a complex background including political corruption of the Manchu regime, foreign aggression during and after the Opium War of 1839–42, agrarian distress, and severe famines that left many people homeless and ready to join the T'ai P'ings.

The titular leader of the rebellion was Hung Hsiu-ch'üan (1814–64), a Cantonese who had struggled in vain to gain office through government civil service examinations. After taking the metropolitan examination at Canton in 1836 he was given nine Christian tracts, which he read cursorily. His third attempt to pass the examination failed in 1837. He was so dismayed that he fell ill, suffered delirium, and had visions of an old man and a middle-aged man in heaven; the latter ordered him to kill demons on earth. After his vision, Hung continued to teach in a village school. Six years later, after his last examination failure in 1843, he decided to give up hope. His cousin then called his attention to the nine Christian tracts. Hung studied the booklets, which had the general title of "Good Words to Exhort the Age" (*Ch'üan-shih Liang-yen*), quotations and paraphrases mainly from the Old Testament, together with sermons. The compiler of the tracts, Liang A-fa (1789–1855), was the first Protestant convert in China. After reading the tracts Hung realized that the old man in his vision was God the Heavenly Father, the middle-aged man was Jesus Christ the Elder Brother, while he himself was the second son of God commissioned to destroy demons, and thus completing a new trinity. Hung and his cousin baptized each other and soon afterward organized the God Worshipers' society.

It was in 1850 that Hung ordered all God Worshipers in various places in mountainous Kwangsi province to resist government troops and to concentrate at Chin-t'ien. Their slogan—to share property in common—attracted many famine-stricken peasants, workers, miners and others. They took Yung-an in Kwangsi on Sept. 25, 1851, and Hung proclaimed himself the heavenly king of the T'ai-p'ing T'ien-kuo, or Heavenly Kingdom of Great Peace. The year 1851 was to be the first year of the new dynasty.

The T'ai P'ings thereupon sought to overthrow the Manchu dynasty, and advanced rapidly from Kwangsi through Hunan and Hupeh along the Yangtze valley. They formed themselves into separate battalions for men and women and behaved much better than the government troops. In March 1853 the T'ai P'ings established their "heavenly capital" at Nanking, and it lasted for 11 years. A northern expedition to take Peking failed but another expedition to reconquer the upper Yangtze valley scored many victories. Victory, however, was followed by a series of murders among the leaders of the rebellion in 1856. Two associate kings with hundreds of their followers were killed; an enormous army was taken away by the assistant king to southwest China.

Meanwhile, the inefficient government troops were replaced by a new force trained in Hunan by Tseng Kuo-fan (1811–1872). A Confucian scholar, Tseng employed his students as officers and created a Confucian army to combat the rebels. Tseng eventually managed to hem Hung's forces in Nanking. The T'ai P'ing attempts to take Shanghai in the 1860s then met with foreign intervention. Western volunteers organized the "Ever-Victorious army" under the command of F. T. Ward and then of C. G. Gordon (*q.v.*), who routed the T'ai P'ings in the greater Shanghai area. Nanking was taken by Tseng's force in July, 1864. By this time Hung Hsiu-ch'üan had committed suicide. Some T'ai P'ings fled to the southern coast and survived until 1866, and some, allied with the "Nien-fei" in North China, continued their anti-Manchu war until 1868. (*See* NIEN REBELLION.)

During their years of power the T'ai P'ings inaugurated many reforms. Their religion was a Chinese pseudo-Christianity. They knew only God the creator of the world, the Ten Commandments and baptism. They recognized the Sabbath and said grace before meals. They did not adopt the Lord's Supper and the Christian ideas of kindness, forgiveness and service to mankind. Their government system was a theocracy. The Heavenly King was both spiritual and temporal ruler, and his four associate kings and an assistant king were civil and military chiefs. All posts were hereditary. The legal code was severe. Organization of the army was elaborate, with strict rules governing soldiers in camp or on the march. The T'ai P'ings planned equal distribution of land according to a primitive form of communism, but did not put this system into practice. Families were graded in a co-ordinated system that took into account the exigencies both of peace and war. There was to be equality between men and women. Monogamy was the rule for the common people, but not for the kings. Prostitution, footbinding and slavery were prohibited, as well as opium smoking, adultery, witchcraft, gambling, and use of tobacco and wine. Chinese language simplification was practised. Westernization and industrialization were planned.

The T'ai P'ing rebellion failed because of poor leadership in military and civil administration, internal dissension, alienation of the Confucian literati, and the combined attack by Tseng's army and foreign-led forces. It ravaged 17 provinces and caused the loss of about 20,000,000 lives.

TAIT, ARCHIBALD CAMPBELL (1811–1882), English divine, archbishop of Canterbury, was born at Edinburgh on Dec. 21, 1811, of Presbyterian parents. He entered Balliol college in 1830 as a Snell exhibitioner from the University of Glasgow. He became fellow and tutor of Balliol and was also ordained deacon (1836) and priest (1838), and served the curacy of Baldon. He never sympathized with the principles of the Tractarian movement, and on the appearance of Tract 90 in 1841 he drafted the famous protest of the "Four Tutors" against it; but this was his only important contribution to the dispute. In 1842 he succeeded Arnold as headmaster of Rugby; and, after a serious illness in 1848, accepted a less strenuous appointment as dean of Carlisle in 1849. During his residence at Carlisle he served on the University commission, restored his cathedral and did much excellent pastoral work. There too he suffered the great sorrow of his life. He had married Catharine Spooner at Rugby in 1843; in the spring of 1856, within five weeks, five of their children died of scarlet fever. He was consecrated bishop of London on Nov. 22, 1856. He became archbishop of Canterbury in 1868. His last years were interrupted by illness and saddened by the death in 1878 of his only son Craufurd, and of his wife.

Tait was constant in his attendance in parliament, and pressed on many measures of practical utility. The modification of the terms of clerical subscription (1865), the new lectionary (1871), the Burials act (1880) were largely owing to him; for all of them, and especially the last, he incurred much obloquy at the time. He played a prominent part also in the royal commissions on ritual (1867) and on the ecclesiastical courts (1881).

Tait was less successful in dealing with matters which called

for the higher gifts of a ruler, and especially in his relations with the liberal trend in modern thought, and the Catholic revival. His object in dealing with questions of faith, as in dealing with the ritual question, was primarily a practical one: he wished to secure peace, and obedience to the law as he saw it. Consequently, after his sympathies had led him to express himself favourably toward some movement, he frequently found himself compelled to draw back. He expressed a qualified sympathy with some of the writers of *Essays and Reviews*, and then joined in the censure of it by the bishops (1861). The same kind of apparent vacillation was found in his action in other cases. Tait was concerned with the Catholic revival during the whole of his episcopate, and above all on the side of ritual. He had to deal with the St. George's-in-the-East riots in 1859, and the troubles at St. Alban's, Holborn, in their earlier stages (1867); he took part as assessor in the privy council judgment in the Ridsdale case (1877); he was more closely concerned than any other bishop with the agitation against confession in 1858, and again in 1877. His method throughout was the same: he endeavoured to obtain a compliance to the law as declared by the courts; failing this, he made the most earnest efforts to secure obedience to the ruling of the Ordinary for the sake of the peace of the Church; after this, he could do nothing. In fact Tait could hardly realize anything but the connection between the English Church and the state. From such a position there seemed to be no escape but in legislation for the deprivation of the recalcitrant clergy; and the Public Worship Regulation act (1874) was the result. A feeling of indignation spread not only among High Churchmen, but among many who cared little for the ritual practices involved. At length, when A. H. Mackonochie was on the point of being deprived of his benefice for contumacy, the archbishop, then on his deathbed at Addington, took steps which resulted in the carrying out of an exchange of benefices (which had already been projected), which removed him from the jurisdiction of the court. This proved to be the turning point; and the ritual difficulty was afterward dealt with from a different point of view, and the Public Worship Regulation act became practically obsolete. The archbishop died on Dec. 3, 1882.

See R. T. Davidson and D. Benham, *Life of Archbishop Tait,* 2 vol. (1891); A. C. Tait, *Catharine and Craufurd Tait* (1880).

TAIT, PETER GUTHRIE (1831–1901), Scottish mathematician and physicist known for his work on thermodynamics, was born at Dalkeith on April 28, 1831. After attending the academy at Edinburgh and spending a session at the university, in 1848 he entered Peterhouse, Cambridge, graduating in 1852. As a fellow and lecturer of his college he remained in Cambridge until 1854 and then left to take up the professorship of mathematics at Queen's college, Belfast. There he joined Thomas Andrews in researches on the density of ozone and the action of the electric discharge on oxygen and other gases. From 1860 to 1901 he was professor of natural philosophy at Edinburgh, where he died on July 4, 1901.

His earliest work dealt mainly with mathematical subjects, and especially with quaternions (*q.v.*), of which he may be regarded as the leading exponent after their originator, Sir William Rowan Hamilton. With the help of Hamilton and Philip Kelland he wrote two textbooks, *Elementary Treatise on Quaternions* (1867) and *Introduction to Quaternions* (1873). He also produced original work in mathematical and experimental physics. In 1864 he published a short paper on thermodynamics, and from that time his contributions to that and kindred departments of science became frequent and important. He worked on thermoelectricity and thermal conductivity, its variation with temperature and its relation to the electrical conductivity of the same material.

From 1879 to 1888 he was engaged on difficult experimental investigations, which began with an inquiry into the corrections required, because of the great pressures to which the instruments had been subjected, in the readings of the thermometers employed by the "Challenger" expedition for observing deep-sea temperatures; his investigations were extended to include the compressibility of water, glass and mercury. Between 1886 and 1892 he published a series of papers on the foundations of the kinetic theory of gases, and about the same time he carried out investigations into impact and its duration.

A selection from Tait's papers was published in two volumes (1898, 1900). With Lord Kelvin he collaborated in writing the well-known *Treatise on Natural Philosophy* (1867), only the first part of which was completed. He collaborated with Balfour Stewart in *The Unseen Universe* which was followed by *Paradoxical Philosophy* (1878).

TAIWAN: *see* FORMOSA.

T'AI-YÜAN (formerly YANGKÜ or YANG-CH'U), capital of Shansi province, China, stands at the northern end of a heavily populated plain on the upper course of the Fen Ho. Ancient Mongol invasion routes lead from the north off the Mongolian plateau and from the south via Ta-t'ung. To the east through the T'ai-hang Shan is the old imperial highway from Peking via Shihmen to T'ai-yüan and then south and west to Sian. Both routes have railways and motor roads. Although the whole area lies within the brown, eroded loess highlands, the fertile T'ai-yüan plain produces an abundance of wheat, cotton and northern fruits and vegetables; sheep on the surrounding hills are raised for wool. There, too, are China's largest known reserves of high-grade bituminous coal. The city was known as the home of nationwide private banking, as a textile and leather centre (gold lacquered leather boxes and trays) and for metal production. Late in the 19th century an arsenal was built using the abundant local coal and iron ore, followed by an ironworks, flour and textile mills. Under Japanese occupation, 1937–45, the city and its industries were vital for the control of north China despite the constant cutting of railway lines by Chinese guerrilla forces. Under the Chinese People's Republic (Communist) the population increased and T'ai-yüan expanded into a major centre for iron and steel, textiles, textile machinery, cement and a phosphorous fertilizer plant (100,000-ton capacity). It has an institute of technology. Pop. (1953) 720,700; (1957 est.) 1,020,000.

(TE. H.)

TAJ MAHAL, the mausoleum built on the south bank of the Jumna river, outside Agra in India, on the orders of the Mogul emperor Shah Jahan in memory of his beloved wife, Arjumand Banu Begum, called Mumtaz Mahal, "chosen one of the palace" (of which Taj Mahal is a corruption). She died in childbirth in the town of Burhanpur in 1631 after having been the emperor's inseparable companion since their marriage in 1612. The building was commenced in 1632, after plans had been prepared by a council of architects from India, Persia, central Asia and beyond; the credit for the final plan is given to one Ustad Isa, either Turkish or Persian, although the master builders, masons, inlayers and calligraphists, like the materials they worked with, came from all over India and central Asia. More than 20,000 workmen were employed daily to complete the mausoleum building itself by 1643, although the whole Taj complex took 22 years to complete, at a cost of 400 lakhs of rupees.

The complex consists of a rectangle measuring 634 yd. by 334 yd. aligned north and south. A central square garden area, 334 yd. on each side, leaves an oblong area at each end; that at the south consists of the sandstone entrance gateway with its attendant service buildings, while that at the north (river) end comprises the mausoleum itself, flanked on the west and east walls by two symmetrically identical buildings, the mosque and its jawab ("answer") respectively. All is enclosed within a high red sandstone boundary wall with octagonal pavilion turrets at the corners, while outside the enclosure at the south are ancillary buildings such as stables, outhouses and guard quarters. The whole complex is the begum's memorial; it was conceived and planned as an entity, since Mogul building practice allowed of no subsequent addition or amendment. Its northern end is the most significant architecturally, with mosque and jawab both facing the mausoleum itself. The mosque and jawab of red Sikri sandstone, with marble necked (not bulbous) domes and architraves and some restrained *pietra dura* surface decoration, contrast well with the mausoleum of pure white Makrana marble. This mausoleum, standing on a 312-ft.-square marble plinth 23 ft. high, is a square of 186 ft. with chamfered corners and with a massive arch in each face, rising to 108 ft.; over all is a bulbous double dome, supported on a tall drum,

the pinnacle of which stands 243 ft. above garden level. The sky-line rhythm is enhanced by parapets over each arch, corner pinnacles and domed kiosks over each corner. At each corner of the plinth stands a three-storied minaret, 138 ft. high to the crowning kiosk; the countersunk face joints of the marble bricks provide textural contrast with the highly finished marble of the mausoleum, but unfortunately recall factory chimney construction to the sophisticated western beholder. Inside the mausoleum is the octagonal chamber, embellished with low-relief patterns and fine *pietra dura*, containing the cenotaphs of the begum and Shah Jahan. These, of marble decorated with superb *pietra dura*, are enclosed by an exquisite perforated marble screen studded with precious stones. A vault below, at garden level, contains the true sarcophagi.

The minarets lead the observer's eye from the mausoleum to its setting; this is now somewhat unsatisfactory, as trees obscure the view of other structures, and from the garden there is some feeling of restlessness; but from the river or from the fort the balance restores itself, and justifies H. R. Nevill's remark that "the Taj . . . is within more measurable distance of perfection than any other work of man" (*Agra Gazetteer*, 1921). Its design, successor in the indigenous tradition to the mausoleums of Humayun and the Khan-i-khanan at Delhi, has been criticized as "too feminine" —thus complimenting the designers' intentions. The Moguls are said to have "built like Titans and finished like goldsmiths"; certainly the Taj Mahal is their finest jewel. *See* ISLAMIC ARCHITECTURE.

BIBLIOGRAPHY.—Percy Brown, "Monuments of the Mughal Period," *Cambridge History of India*, vol. iv (1937), *Indian Architecture: the Islamic Period* (1942); for the controversy over the attribution of the design to a European, *see* V. A. Smith, *History of Fine Art in India and Ceylon*, pp. 182–185 (1930); E. B. Havell, *A Handbook to Agra and the Taj*, appendix i, new ed. (1924). (J. B.-P.)

TAK, a mountainous province of Thailand on the Burmese border. Area 6,027 sq.mi. Pop. (1960) 165,104. The Ping river runs through its northeastern portion, and the provincial capital, Tak or Rahaeng (pop., 1957, 11,641), is the river's major commercial centre south of Chiangmai. The town is an important crossroads of the national highway system, and a motor road, following an ancient caravan route to Burma, now traverses the province from Tak to Maesot (pop., 1957, 9,615). (G. W. Sk.)

TAKAMATSU, capital city and commercial centre of Kagawa prefecture, Jap. Pop. (1960) 228,172. Serving as the transportation hub of Shikoku Island, Takamatsu has a small but flourishing port that is linked by railroad ferry to Uno on the Inland sea coast of Honshu. The water front is dominated by a breakwater, port facilities, a small industrial zone on reclaimed land and extensive salt fields. Federal agencies for Shikoku have their headquarters in Takamatsu. Ritsurin park, once the estate of the Matsudaira family, and Inland sea scenery viewed from Yashima, an elevated tableland noted for its relics of the 12th-century Taira clan, attract many tourists. (J. D. Ee.)

TAKAOKA, a town in Toyama prefecture, central Japan. Pop. (1960) 135,190. In 1609 Maeda Toshingaga, feudal lord of the Kaga clan, built a castle there and Takaoka developed. After his death the castle town flourished as a commercial and industrial centre. With the annexation of the old port, Fushiki, in 1922, Takaoka became one of the busiest port towns on the Japan sea. It is also an important railway junction. There are factories producing copper, iron and lacquer ware as well as cotton-spinning and textile-dyeing industries. (R. B. H.)

TAKASAKI, town in Gumma prefecture, east Japan, situated on a tributary of the Tone river. Pop. (1960) 142,152. Takasaki is a railway communication centre. A typical castle town, it became increasingly important as a commercial centre, especially after the Meiji era (1868–1912), with the growth of the railroads. Various manufacturing industries have developed, including flour milling and machinery. The Yorimasa shrine is located in Takasaki park. (R. B. H.)

TAKIN, a rare, little-known goat antelope (*Budorcas taxicolor*), which inhabits high, rough country from Bhutan to southern Shensi province, China. The takin is clumsily built, with yellowish-brown or gray hair and curiously curved horns, which recall those of the gnu. This shy animal is hunted for food by the people of its native regions, but very few specimens have been captured alive. Its nearest relative appears to be the musk ox (*q.v.*). *See* BOVIDAE.

TAKLA MAKAN, a desert in central Asia, the major central division of the Tarim basin. In general the Takla Makan is a region of drift sand and moving sand dunes, and is a waterless area except for the Khotan and Keriya rivers, which carry water northward into the desert. The sand dune desert is uninhabitable away from these rivers and from the Tarim river, which skirts the northern margins. The sand dunes occupy chiefly the south and southwest parts of the Takla Makan, where the full force of the northeast winds is felt. In this area there are two systems of dunes; one, of high chains, stretches from east to west, and the second, of transverse dunes, runs from north to south or northeast to southwest. The steeper sides of the dunes generally face toward the south, away from the direction of the prevailing winds, though there is local variation in alignment, facing and movement.

Between the lower Tarim river, in the northeast, and the Charchan desert, in the southeast, the surface generally is different from that of the rest of the Takla Makan. In this region the sand dunes are interrupted by tracts of level soil, or by areas of old channels, bare mesas and erosional remnants, swept clean by the wind. This is the zone in which the Tarim river and the lake, Lop Nor, have wandered repeatedly, so that in places there is fresh to brackish water available near the surface.

Vegetation and animal life are almost nonexistent in the dry heart of the Takla Makan, but along the permanent streams and locally in the eastern sector various steppe plants, reeds, tamarisks and poplars provide a thin scattering of plant life. On the lower Tarim river, and around Lop Nor, heavy reed growth does occur. The animal life of the region is concentrated at localities providing water and vegetation. Hares, rodents, foxes, wolves, wild pigs, a few antelope and, in a few places in the east, wild camels, are among the land animals. In general the animal population of the eastern sector is greater than that of the western zone. A variety of fish and birds are found along the lower Tarim river and throughout Lop Nor.

The climate of the Takla Makan is one of extremes. Winter temperatures as low as −23° or −24.5° C. (−10° or −12° F.) occur almost everywhere, and a temperature of −30° C. (−22° F.) has been observed in the southeast, where winter snowstorms sometimes occur. Temperatures as high as 30° C. (86° F.) have been recorded in late spring, but it is likely that higher temperatures occur in the interior dune areas in midsummer. Suffocating sandstorms occur, often enveloping the desert for days and producing an impenetrable dust haze.

TAKORADI: *see* SEKONDI-TAKORADI.

TALAVERA DE LA REINA, a town of central Spain, in the province of Toledo, on the right bank of the river Tagus, and on the Madrid-Cáceres railway. Pop. (1950) 21,728 (mun.). Talavera is of great antiquity, the Caesobriga of the Romans. Portions of the triple wall which surrounded it remain standing and the Arco de San Pedro is one of its Roman gates restored. Among the ancient buildings are the Torres Albarranas, built by the Moors in the 10th century, and the Gothic collegiate church. The bridge of 35 arches across the Tagus dates from the 15th century.

Talavera, Battle of, 1809.—For the operations which culminated in the famous battle of Talavera between the English and the French and those which followed that engagement, *see* PENINSULAR WAR. Sir Arthur Wellesley (afterward Duke of Wellington), the British commander, acting in co-operation with Lieutenant-General Cuesta's Spanish army, took position on July 27, 1809, on the Upper Tagus, protected by his advanced guard. His line, facing due east, ran north from the right bank of the river to a ridge running parallel to the Tagus, beyond which ridge, also parallel to the river, lay the Sierra de Montalban. Cuesta's men with their right flank resting on the river held Talavera itself and the close country to the northward of it; Wellesley's right

connected with Cuesta's left, and his line stretched away northward to the ridge. The Sierra was not occupied until the second day. On the first day the French attacked the allied positions but were unable to breach the defenses. On the 28th the French renewed their efforts and mounted several more attacks which were thrown back. Wellesley finally decided the day by a counter-attack with the 48th regiment, made with great intrepidity and steadiness. The guards, with splendid discipline, resumed their positions, and eventually the French fell back. Failure all along the line and heavy losses left King Joseph no alternative but to retire toward Madrid. The French lost 7,268 men out of 46,138 present, the British 5,363 out of 20,641; the Spanish losses were officially returned at 1,201 out of some 36,000 present.

TALBOT, the name of one of the oldest families in the English nobility, which traces its descent from RICHARD TALBOT (d. 1174–75), who held Eccleswall and Linton, in Herefordshire, in the time of Henry II. Records mention several persons called Talbot living earlier in England, and in Normandy before 1066, among them Geoffrey Talbot (d. 1140), an opponent of King Stephen; but since Talbot was at first a nickname and not a hereditary surname, their relationship is obscure.

The descendants of Richard Talbot, with whom the proved pedigree begins, ranked for several generations among the lesser families of the Welsh border counties. GILBERT TALBOT (1276–1346) took part with other Marcher lords against Edward II's favourites, the Despensers, who had wrested estates from his daughter-in-law Elizabeth Comyn. With his son, Richard, he was taken prisoner by the royal forces at Boroughbridge (1322) but was later pardoned and restored to his estates. He was afterward king's chamberlain and justice of south Wales, and was summoned to parliament as a baron (1332). His son, RICHARD (*c.* 1305–56), 2nd lord, claimed extensive lands in Scotland in right of his wife, Elizabeth, daughter of John Comyn of Badenoch, and in 1332 he joined Edward Balliol in his invasion of Scotland, being present at the victory of Dupplin (Aug. 12). Captured by the Scots in Sept. 1334, he was released for a ransom of £2,000. His wife, also a coheiress of the Valence earls of Pembroke, brought him the manor of Painswick in Gloucestershire and the castle of Goodrich on the river Wye; their grandson later acquired in her right the Irish lordship of Wexford (1389). Richard afterward fought with the English armies in France at Morlaix (1342) and Crécy (1346). His son, GILBERT (*c.* 1332–87) served in France and also Spain. The family estates in Herefordshire, Gloucestershire, Oxfordshire and Kent were further increased by the marriage of Gilbert's son, RICHARD (*c.* 1361–96) to Ankaret, daughter and heiress of John, 4th Lord Strange of Blackmere, who brought him Whitchurch in Shropshire and other lands. His son, GILBERT (*c.* 1383–1418), 5th lord, campaigned in Wales against Owen Glendower, and, after proving himself one of Henry V's most vigorous captains in France, died during the siege of Rouen. On the death of his infant daughter and heir (1421), he was succeeded as 7th lord by his brother, JOHN (1384–1453), whose marriage to Maud, heiress of the lords Furnival, had brought him wide estates in Yorkshire, including Sheffield castle, which became a favourite family residence until 1618. In reward for his distinguished services in France he was created earl of Shrewsbury (1442) and earl of Waterford (1446).

The 1st earl's son, JOHN (*c.* 1413–60) was chancellor of Ireland during his father's lifetime and treasurer of England (1456–58). A strong Lancastrian, he was rewarded with grants from the forfeited Yorkist estates (1459–60) and was killed fighting for Henry VI at Northampton (July 1460). JOHN (1448–73), 3rd earl, at first shared his father's loyalties and was present in Henry VI's army at the second battle of St. Albans and at Towton (1461), but afterward made his peace with the new king, Edward IV, and was appointed chief justice of north Wales in 1471. His son, GEORGE (1468–1538), 4th earl, began a family tradition of devoted service to the Tudor kings. He fought at the battle of Stoke (1487), was steward of the household (1506–38), commanded the army which invaded France in 1513, and, as king's lieutenant in the north, crushed the rebels of the Pilgrimage of Grace (1536). FRANCIS TALBOT (1500–60), who succeeded his father as 5th earl, joined in the invasions of Scotland (1542 and 1544) and spent much of his life on the Scottish borders, being president of the council of the north from 1549 until his death. His son, GEORGE (*c.* 1522–90), 6th earl, who was styled Lord Talbot during his father's lifetime, was selected by Elizabeth I for the unenviable position of custodian of Mary Stuart, who spent the years 1569–84 in his castles at Sheffield and Tutbury or at Chatsworth house. His task was complicated by the limited funds allowed him by Elizabeth, and by the malicious attempts to discredit him of his second wife, Bess of Hardwick (*see* SHREWSBURY, ELIZABETH TALBOT, Countess of).

The 6th earl was succeeded in turn by two of his sons, but in 1618 the direct male line descended from the first earl ceased, and the title and estates passed to the head of a cadet branch of the family founded by SIR GILBERT TALBOT (d. 1517) of Grafton, Worcestershire, a younger son of the 2nd earl. This was GEORGE TALBOT (1566–1630), 9th earl, a Roman Catholic like nearly all his descendants until 1856, who had been ordained priest before he succeeded to the title. His great great nephew, CHARLES (1660–1718), 12th earl, was raised to the dignity of a duke for his services to William III (*see* SHREWSBURY, CHARLES TALBOT, Duke of), but as he left no son this title died with him and the earldom passed to his cousin, GILBERT (1673–1743), a Roman Catholic priest who never assumed the title. From this time the direct line of Sir Gilbert Talbot of Grafton began to fail. A nephew three times succeeded to an uncle, and the title then passed to a cousin, BERTRAM ARTHUR TALBOT (1832–56), the 17th earl, who died unmarried. The lands were claimed under his will by Lord Edmund Howard, a younger son of the 14th duke of Norfolk and afterward Viscount Fitzalan, but the courts decided that the title and estates should remain together, and a successor to the earldom was found in HENRY JOHN CHETWYND-TALBOT (1803–68), Earl Talbot, head of another line of the descendants of Sir Gilbert Talbot of Grafton, who became the 18th earl of Shrewsbury. The head of this family a century before had been WILLIAM TALBOT (d. 1730), successively bishop of Oxford, Salisbury and Durham. His son, CHARLES (1685–1737), lord chancellor (1733–37), was created Baron Talbot of Hensol in 1733. Charles's son, WILLIAM (1710–82), was raised to the dignity of Earl Talbot in 1761, and William's nephew JOHN CHETWYND (1750–93) added the title of Viscount Ingestre (1784), now usually borne by the earl of Shrewsbury's eldest son. All these titles have since been united in the line descended from the 18th earl. (C. D. R.)

TALBOT, MARY ANNE (1778–1808), the "British Amazon," was born in London on Feb. 2, 1778. She believed herself to be the illegitimate child of the 1st Earl Talbot. Early in her career she eloped, in the disguise of a boy, with a captain. In 1792 she was a drummer in Flanders. In the capture of Valenciennes her lover was killed; and Mary Anne deserted and became cabin boy on a French lugger, which she asserted was captured by the British, who transferred her to the "Brunswick," where she served as a powder monkey, being wounded in Lord Howe's victory of June 1, 1794. For this she later received a small pension. When the wound healed she again went to sea, was captured by the French, and imprisoned for a year and a half. Her sex was not discovered until shortly after she was seized by a pressgang. She finally became a household servant to Robert Kirby, a London publisher, who included an account of her adventures in his *Wonderful Museum* (1804) and in *Life and Surprising Adventures of Mary Anne Talbot* (1809). She died on Feb. 4, 1808.

TALBOT, WILLIAM HENRY FOX (1800–1877), English pioneer in photography (*q.v.*), was born at Melbury house, near Evershot, Dorset, on Feb. 11, 1800, and died there on Sept. 17, 1877. He was educated at Harrow and at Trinity college, Cambridge. Before L. J. M. Daguerre in 1839 exhibited pictures taken by the sun, Talbot had obtained similar success, and as soon as Daguerre's discoveries became known he communicated the results of his experiments to the Royal society. In 1841 he made known his discovery of the calotype or Talbotype process and, after the discovery of the collodion process by F. S. Archer (1851), devised a method of instantaneous photography. With Rawlinson

and Hincks he was one of the earliest to decipher the cuneiform inscriptions from Nineveh.

His works include *Pencil of Nature* (1844); *Hermes or Classical and Antiquarian Researches* (1838–39); *Illustrations of the Antiquity of the Book of Genesis* (1839); *English Etymologies* (1846).

TALBOT OF HENSOL, CHARLES TALBOT, 1ST BARON (1685–1737), lord chancellor of England, the eldest son of William Talbot, bishop of Durham, a descendant of the 1st earl of Shrewsbury, was educated at Eton and Oriel college, Oxford, and became a fellow of All Souls college in 1704. He was called to the bar in 1711, and in 1717 was appointed solicitor general to the prince of Wales. Having been elected a member of the house of commons in 1720, he became solicitor general in 1726, and in 1733 he was made lord chancellor and raised to the peerage with the title of Baron Talbot of Hensol. He died on Feb. 14, 1737. Talbot enjoyed the reputation of a wit; he was a patron of the poet Thomson, and Butler dedicated his *Analogy* to the lord chancellor.

See Lord Campbell, *Lives of the Lord Chancellors and Keepers of the Great Seal*, 8 vol. (1845–69).

TALC is the mineral name for the familiar hydrous magnesium silicate, a common mineral occurring as veins, foliated masses and as a constituent in certain rocks in metamorphic terranes. Talc is distinguished from almost all other minerals by its extreme softness. The hardness of 1 (easily scratched with the fingernail) imparts a soapy or greasy feel which accounts for the name soapstone or steatite for the compact aggregates of talc. Soapstones have been employed since ancient times for carvings, ornaments and utensils. Assyrian cylinder seals, Egyptian scarabs and Chinese figure carvings are notable examples. The resistance to attack from most reagents and to moderate heat makes soapstones especially suitable for sinks and countertops. Talc is also used for lubricants, leather dressings, toilet and dusting powders and certain marking pencils. The major industrial uses of talc and soapstone are in ceramics, paint, rubber, insecticides, roofing and paper.

The colour of talc is white, gray, yellow or various shades of green with a pearly or silvery lustre. Talc is usually found in foliated masses of thin, small, sometimes hexagonal plates. The individual plates easily separate along the perfect basal cleavages into thin flexible but inelastic lamellae (cleavage fragments of muscovite (*q.v.*) which can be confused with talc are elastic). Pyrophyllite (*q.v.*) can be distinguished from talc only by optical or chemical methods.

Mode of Occurrence and Composition.—Talc is found as a metamorphic mineral in the lower facies of metamorphism and is often associated with other minerals such as serpentine, tremolite (amphibole) (*qq.v.*) and forsterite (olivine; *q.v.*) and almost always associated with carbonate: calcite, dolomite or magnesite (*qq.v.*). Talc, $Mg_3Si_4O_{10}(OH)_2$, can occur as an alteration of a pre-existing mineral such as tremolite or forsterite as evidenced by preserving the crystal outlines of the pre-existing minerals. Talc also occurs as veins and masses formed at the expense of and replacing pre-existing mineral aggregates. Soapstones have two general types of occurrences: (1) a large group of soapstones are found intimately associated with metamorphosed carbonate rocks probably originally rich in magnesium. By the addition of water and silica and the removal of carbon dioxide, talc can be formed:

$$3MgCa(CO_3)_2 + 2H_2O + 5SiO_2 \rightarrow 2Mg_3Si_4O_{10}(OH)_2 + 3CaCO_3 + 3CO_2$$

(2) a large group of soapstones are found intimately associated with olivine- and/or pyroxene-rich igneous rocks which have been extensively altered by the addition of water and carbon dioxide or water and silica to form talc, for example:

$$\underset{\text{Forsterite}}{3Mg_2SiO_4} + 2H_2O + 5SiO_2 \rightarrow \underset{\text{Talc}}{2Mg_3Si_4O_{10}(OH)_2}$$

or the reaction may be as follows:

$$\underset{\text{Forsterite}}{4Mg_2SiO_4} + H_2O + 5CO_2 \rightarrow \underset{\text{Talc}}{Mg_3Si_4O_{10}(OH)_2} + \underset{\text{Magnesite}}{5MgCO_3}$$

A sequence of mineral formation ending in talc is very commonly observed: olivine plus pyroxene is altered to tremolite, which is altered to serpentine, which in turn is altered to talc plus carbonate. The alteration of serpentine by the addition of silica to form talc is common, with the result that serpentine-rich rocks and soapstones are usually found together. The conditions for the formation of talc apparently are often met in metamorphism—as evidenced by the world-wide occurrence of soapstones in many metamorphic terranes.

One of the remarkable features about talc is its simple, almost constant composition. Unlike other silicates, even closely related ones, talc appears to be unable to accept iron or aluminum into its structure and form solid solution series (*see* MINERALOGY: *The Nature of Minerals: Solid Solution*). This is especially curious because an iron analogue of talc is known, and the structurally related chlorite (*q.v.*) forms at least a partial solid solution series between the iron and magnesium end members.

Crystal Structure.—The crystal structure of talc, a phyllosilicate, accounts for its physical properties. The phyllosilicates are characterized by a hexagonal sheet structure arrangement of the SiO_4 tetrahedral groups formed by the sharing of three oxygen atoms from each SiO_4 tetrahedron with neighbouring SiO_4 tetrahedra with the silicon atoms arranged at the corners of hexagons. The fourth (unshared) oxygen atom of the tetrahedron is capable of forming chemical bonds with other metal atoms. (For description of this structure *see* AMPHIBOLE; PYROXENE.) In most phyllosilicates, talc included, the unshared oxygens are on the same side of the sheet. Two such sheets (oriented such that their unshared oxygens face each other) are bonded together by the magnesium atoms with the remaining charges balanced by OH groups (located at the centres of the hexagonal groups) also bonded to the magnesium atoms. This arrangement results in a double-sheet structure which completely satisfies the valence demands of the atoms. Therefore, these double-sheet units cannot be bonded to adjacent units by other metal atoms satisfying remaining charges. Consequently, the talc crystal is made up of stacks of these double-sheet units held together in the stack by the weakest of chemical bonds—the van der Waals' forces. Thus, this stacking can be disturbed by slight forces causing the slipping of the double-sheet units along this perfect cleavage direction.

(G. W. DEV.)

TALCA, a province of Chile, bounded on the north by Curicó, east by Argentina, south by Linares and Maule and west by the Pacific. The area, since being separated from the province of Curicó, is 3,722 sq.mi.; pop. (1960) 205,448. In the east the Andean slopes cover a considerable part of its territory, and in the west another large area is covered by the coast range. Between these is the central valley of Chile in which the population and industries of the province are chiefly concentrated. The lower mountainous parts are well wooded. The intermediate plain is fertile and devoted to wheat, grapes and stock. The capital of the province is Talca (pop. [1960] 80,277), on the Río Claro, 156 mi. S. of Santiago by rail. The city, founded in 1692 and revived in 1742, has a variable climate.

TALCAHUANO, a seaport of the province of Concepción, Chile, on the bay of Talcahuano, 8 mi. N.W. of the city of Concepción. Pop. (1960) 99,231 (mun.). It has the best harbour on the Pacific coast of South America and is one of the most important ports of southern Chile. The Chilean government established its chief naval base there.

TALE, a general term, in the usual acceptance of the word, for fictitious narratives, long or short, ancient or modern. In this article "tale" is used as equivalent to the German *Volksmärchen* or the French *conte populaire*. Thus understood, popular tales mean the stories handed down by oral tradition from an unknown antiquity. So understood, popular tales are a subject in mythology. The Homeric epics, especially that of the *Odyssey*, contain adventures (for example, the husband who returns in disguise) which are manifestly parts of the general human stock of popular narrative. Other examples are found in the Rig-Veda and in the myths which were handled by the Greek dramatists. The *Thousand and One Nights* (*q.v.*) is full of popular tales, and

popular tales are the staple of the medieval *Gesta Romanorum* and of the collections of G. Straparola and other Italian storytellers. In all these the story, long circulated among the people, is handled with conscious art. *Histoires ou contes du temps passé* of C. Perrault (1697) is one of the earliest collections of tales which were taken down as they were told by nurses to children. The success of Perrault's tales brought the genre into fashion, and the Comtesse d'Aulnoy invented, or in some cases adapted, *contes*, which retain popularity. But the precise and scientific collection of tales from the lips of the people is not much earlier than the 19th century. The chief impulse to the study was given by the brothers Jacob and Wilhelm Grimm. The first edition of their *Kinder- und Haus-Märchen* was published in 1812. In addition to the *märchen* of Indo-European peoples, the Grimms became acquainted with some Malay stories, some narratives of Bechuanas, Negroes, American Indians and Finnish, Estonian and Magyar stories. *See* NOVEL. (A. L.; X.)

TA-LI, a small but historic city in southwest China, about 170 mi. N.W. of the Yünnan provincial capital of Kunming and located on the western shore of Erh lake. Erh lake occupies a deep structural basin; it is about 30 mi. long and from 2 to 5 mi. wide and its surface is 6,700 ft. above sea level. The west shore of the lake comprises a narrow plain, running the length of the lake and rising on the west to the Ts'ang Shan, a massive mountain range topping 14,000 ft.

Ta-li was founded about 746 A.D. as the capital of the Thai (Tai) people's state of Nan Chao. It remained the capital until the Mongols overran the region in the 13th century and the Thai moved southward. Both the ancient Burma-China caravan route and the World War II Burma road touched the southern corner of the lake plain at Hsia-kuan. Much of the city was destroyed by an earthquake in 1925 and was not rebuilt. The Ta-li plain is the home of the Min-chia people, related to the Thai, who have absorbed much of Chinese culture and who comprise about one-third the 20,000 residents of the city of Ta-li. Ta-li is essentially a regional trade and political centre notable for its fine marble products. In the late 1950s the region became a Min-chia autonomous area. (J. E. Sr.)

TALIESSIN: *see* WELSH LITERATURE.

TALLADEGA, a city of Alabama, U.S., the seat of Talladega county, is located 57 mi. E. of Birmingham in the foothills of the Blue Ridge mountains. The city is in an agricultural and dairying region, with marble and limestone quarries and iron mines. The chief industrial products are cotton textiles, cottonseed oil, machine parts, pipe fittings, soil pipe, lumber, woolen worsted fabric and yarn. Talladega college, a coeducational institution founded in 1867 and affiliated with the Congregational Christian Church (United Church of Christ), and the Alabama School for the Deaf and Blind are located there. Nearby are Cheaha State park and Talladega National forest. The name Talladega, also applying to mountains south and east of the town, is Indian for "border town" as its site was on the edge of the Creek Indians' land. Andrew Jackson defeated a large force of Indians there in 1813. Talladega was settled in the 1830s and incorporated in 1835; the county was established in 1832. For comparative population figures *see* table in ALABAMA: *Population.* (B. Cr.)

TALLAGE, a term employed, while it was in ordinary usage, in the general sense of "tax," and applied to various seignorial, royal and municipal taxes (most of them also known by other names such as "aid"), but particularly to a tax imposed by the lord of an estate upon his unfree tenants. Tallage of this kind was already an established seignorial perquisite in England, as elsewhere in western Europe, in the 12th century. Its arbitrariness was generally greater than that of similar aids taken by lords from free tenants. Its frequency or its amount or both might be at the lord's will, though on many estates in the 13th century it had already become a fixed charge. In England from the reign of Henry II a lord sometimes required specific royal authority to take a tallage—when, for instance, the estate to be tallaged was a former royal estate.

In England at the end of the 12th century, "tallage" established itself as the name of a royal tax (developed by Henry II but not in principle novel) levied on estates in the king's hand and on boroughs. It was assessed by the king's itinerant justices, who had administrative as well as judicial duties, or by special commissioners. The assessors usually negotiated with the community of a borough or estate for a lump sum, but sometimes took the less popular course of tallaging individuals separately. Royal tallages were most frequent during John's reign; objection to them found expression in the Magna Carta. Under Henry III an interval of two to four years was usual and the average yield seemed no greater than before. At its highest, the yield of a tallage exceeded £5,000, and payment was prompt. London's contribution was by far the largest single item, sometimes exceeding a third of the whole. In the reign of Edward I, as the summons of representatives of boroughs to parliaments became more frequent, parliamentary taxation of boroughs and the king's estates was preferred to tallage. Edward I took a tallage in 1304 after a lapse of 36 years. It was last taken in 1312. An attempt to revive it in 1332 was abandoned in favour of a parliamentary grant. (ER. S.)

TALLAHASSEE, a city of Florida, U.S., the capital of the state and the seat of Leon county, is in the northern part of the state 166 mi. W. of Jacksonville, 200 mi. E. of Pensacola and 20 mi. N. of the Gulf of Mexico. The city and the surrounding region are characterized by rolling hills, lakes, streams and giant magnolia and oak trees. Leon county and the 12 counties immediately to the west and east comprise the "big bend" of north central Florida, an agricultural area producing livestock, "shade-cured" (formerly called Spanish or Florida) tobacco, pecans, tung oil trees and diversified farm products. Among the industries of the city are lumber-planing mills, naval store refineries and pecan processing plants. It is a key wholesaling and distribution point for northwest Florida and southwest Georgia. It is the seat of two coeducational universities, Florida State university and the Florida Agricultural and Mechanical university (*see* FLORIDA: *Education*). Among its stately homes are the Grove (completed in 1830), the Columns (1835), Goodwood (1843) and the governor's mansion (1957).

In 1539–40, Hernando De Soto and a Spanish expedition spent the winter in the vicinity, this incident leading to a local assumption that the first observance of Christmas in the present United States was conducted in or nearby the site at that time. Other Spaniards, while fighting the Apalachee Indians of the region, are supposed to have fortified a hill near the site in 1638. By 1675 seven Franciscan missions were established in the region, San Luis de Talimali, in the western section of the present city, being the most important. This mission, sometimes called Fort San Luis, was destroyed and the Apalachee Indians were dispersed by Gov. James Moore of South Carolina during Queen Anne's War (the War of the Spanish Succession, 1701–13), when he invaded Florida to punish the Spanish for having incited Indian attacks against white settlers in South Carolina. Tallahassee then acquired its name from a Creek Indian word meaning "abandoned village." From this time until Spain ceded Florida to the United States in 1821, Tallahassee remained quite insignificant.

When Florida became a U.S. territory it had two capitals, one in St. Augustine and one in Pensacola. The first territorial legislature met in Pensacola in 1822, the second in St. Augustine the next year. Tallahassee was named the permanent capital in 1823 by the territory's American settlers; it was incorporated in 1825 and became the state capital when Florida entered the union in 1845.

Before the American Civil War Tallahassee became a trade centre for the rich cotton plantation country of middle Florida, partially because of its connection with the little port of St. Marks nearby. Negro slavery was more prevalent in Leon and adjoining counties than elsewhere in the state. Because it was so far removed from the significant battle areas, Tallahassee was the only state capital in the Confederacy east of the Mississippi river which was not occupied by Federal troops during the Civil War. In the late 1800s and early 1900s, when south Florida entered its boom era, Tallahassee declined as a commercial and business centre. After 1940 it regained importance because of its position as the governmental centre of the state. The city has a council-

manager form of government, in effect since 1920. For comparative population figures *see* table in FLORIDA: *Population.*
(W. T. Jo.)

TALLAPOOSA, a river of northwestern Georgia and east central Alabama, U.S., rises in the piedmont area of western Georgia about 30 mi. W.N.W. of Atlanta and flows southwest in an irregular, steplike course for about 268 mi. to where it joins the larger Coosa river about 10 mi. N. of Montgomery, Ala., to form the Alabama river. Its only large tributary is the Little Tallapoosa which joins it about midway in its course. All but the lower part of the drainage basin of about 4,500 sq.mi. lies in the Alabama-Georgia piedmont. Falls at Tallassee, Ala., chief city on the Tallapoosa, about 43 mi. upstream from its mouth, and a steep gradient above that prevented use of the river for navigation. Three private power dams (Martin, Yates and Thurlow) above Tallassee have created reservoirs such as Lake Martin (1,630,000 ac.ft.) for river control and recreation as well as power.

The name Tallapoosa is of Creek origin and many Indian villages were situated along the lower river before the 19th century. The Creek War battle of Horseshoe Bend (1814) was fought in a river bend near what is now the northern end of Lake Martin, about 9 mi. N. of Dadeville, Ala. (M. W. M.)

TALLCHIEF, MARIA (1925–), U.S. ballet dancer noted for the crisp perfection of her technique, was born in Fairfax, Okla., Jan. 24, 1925, of American Indian descent. After studying with Bronislava Nijinska she joined Ballet Russe de Monte Carlo in 1942 and soon became a leading dancer. In 1947 she was guest artist at the Paris Opéra, and in 1948, the year it was founded, she joined the New York city ballet as prima ballerina. Tallchief particularly excelled in the roles created for her by George Balanchine in *The Firebird, Orpheus* and *The Nutcracker.*
(LN. ME.)

TALLEMANT DES RÉAUX, GÉDÉON (1619–1692), French writer of informative and entertaining *Historiettes,* or short biographies. Born at La Rochelle on Oct. 2, 1619, of a rich Protestant family, Tallemant went early to Paris and began to frequent literary circles. In 1646 he married Élisabeth Rambouillet in the Protestant temple at Charenton. His later life was made miserable by family bankruptcy and by separation from his wife. She was received into the Catholic Church in 1665, he not until July 1685, about three months before the revocation of the Edict of Nantes. Tallemant died in Paris on Nov. 10, 1692.

Tallemant published nothing in his lifetime save a few poems in anthologies. His *Historiettes* were not published till 1834, from a folio manuscript that had appeared in a Paris auction. This contains a mass of particulars about leading men and women in Parisian society and French public life of the first half of the 17th century. Tallemant appears to have started writing in 1657 from data collected earlier. A good listener, he also took the trouble to seek out well-informed authorities for his lives (such as Boisrobert on Richelieu and Racan on Malherbe), with the aim of recording anything of interest that was not in the printed histories. His new, disturbing and apparently chatty information about dignified persons was at first decried, but research has done much to establish its reliability. These acute jottings, often so near to the actual event, may be considered a firsthand source and have been useful as a corrective to later interpretations. There are modern editions by G. Mongrédien, 8 vol. (1932) and in the "Pléiade Series" by A. Adam (1960–).

See E. Magne, *La Joyeuse Jeunesse . . .* (1921) and *La Fin troublée de Tallemant des Réaux* (1922); also E. Gosse, *Tallemant des Réaux or the Art of Miniature Biography* (1925). (W. G. ME.)

TALLEYRAND-PÉRIGORD, CHARLES MAURICE DE (1754–1838), French diplomatist and statesman, was born at Paris on Feb. 12 or 13, 1754, the son of lieutenant general Charles Daniel de Talleyrand-Périgord. His parents, descended from ancient and powerful families, were in constant attendance at the court of Louis XV. In his third or fourth year, while under the care of a nurse in Paris, he fell from a chest of drawers and injured his foot for life. This accident darkened his prospects; for though by the death of his elder brother he should have represented the family and entered the army, yet he forfeited the rights of primogeniture, and the profession of arms was thenceforth closed to him. At the age of 8 he was sent to the Collège d'Harcourt at Paris, and, at 13 to St. Sulpice, where he conceived a dislike of the doctrines and discipline thrust upon him. After a visit to his uncle, the archbishop of Reims, he returned to St. Sulpice to finish his preliminary training for the church, but in his spare time he read the works of Montesquieu, Voltaire and other writers who were beginning to undermine the authority of the *ancien régime,* both in church and state. As subdeacon he witnessed the coronation of Louis XVI at Reims, but he did not take priest's orders until four years later. While rejecting the authority of the church in the sphere of dogma and intellect, he observed the proprieties of life, and respected the outward observances of religion.

During his life at Paris he frequented the salon of Madame de Genlis, and there formed his ideas in favour of political and social reform. After taking his licentiate in theology in March 1778, he gave little more attention to theological studies. Nevertheless his ability and his social position gained for him in the year 1780 the position of agent-general of the clergy of France. The growing claims of the state on the exchequer of the clergy made his duties responsible. At the extraordinary assembly of the clergy in 1782 he made proposals, by one of which he sought, though in vain, to redress the most glaring grievances of the underpaid *curés.* Though the excellence of his work as agent-general in the years 1780–86 was fully acknowledged, yet he did not gain a bishopric until the beginning of the year 1789, probably because the king disliked him as a freethinker. He now became bishop of Autun, and was installed on March 13.

The Revolution.—The first important act of the new bishop was to draw up a program of the reforms which he desired to see carried out by the states-general of France. It comprised the following items: the formation of a constitution which would strengthen the monarchy by calling to it the support of the whole nation, the drafting of a scheme of local self-government on democratic lines, the reform of the administration of justice and of the criminal law and the abolition of the most burdensome of feudal and class privileges.

His influence in the estate of the clergy, however, was cast against the union of the three estates in a single assembly, and he voted in the minority of his order which in the middle of June opposed the merging of the clergy in the National Assembly. Thereafter he inclined more and more to the democratic side. In July he was chosen as one of the committee to prepare a draft of a constitution; and in the session of the assembly which the comte de Mirabeau termed the *orgie* of the abolition of privileges (Aug. 4) he intervened in favour of discrimination and justice. On Oct. 10 he proposed to the assembly the confiscation of church lands to the service of the nation, but on terms rather less rigorous than those in which Mirabeau (*q.v.*) carried the proposal into effect on Nov. 2. He identified himself in general with the left of the assembly. The course of events harmonized with the anticlerical views of Talleyrand, and he gradually loosened the ties that bound him to the church. He took little part in, though he probably sympathized with, the debates on the measure known as the Civil Constitution of the Clergy. When the Assembly sought to impose on its members an oath of obedience to the new decree, Talleyrand and three other bishops complied out of the thirty who had seats in the Assembly. The others, followed by the greater number of the clergy throughout France, refused, and thenceforth looked on Talleyrand as a schismatic. He did not long continue to officiate, as many of the so-called "constitutional" clergy did; for, on Jan. 21, 1791, he resigned the see of Autun, and in the month of March was placed under the ban of the church by the pope.

Just before his resignation he had been elected, with Mirabeau and Sieyès, a member of the department of Paris; and for some eighteen months he supported the cause of order in the turbulent capital. Though he was often on strained terms with Mirabeau, their views generally coincided. Talleyrand's reputation for immorality, however, was as marked as that of Mirabeau. While excelling Mirabeau in suppleness and dexterity, Talleyrand lacked the force of character possessed by the great "tribune of the

people"; and his influence was gradually eclipsed by the Girondins and the Jacobins.

Debarred from election to the second National Assembly (known as the Legislative) by the self-denying ordinance passed by the "constituents," Talleyrand, at the close of 1791, sought to enter the sphere of diplomacy. The condition of affairs on the continent seemed to French enthusiasts to presage an attack by the other powers on France. In reality those powers were far more occupied with the Polish and eastern questions than with the affairs of France; and the declaration of Pilnitz, drawn up by the sovereigns of Austria and Prussia, which appeared to threaten France with intervention, was recognized by all well-informed persons to be "a loud-sounding nothing." The French foreign minister, Delessart, hoping to confirm Pitt in his intention of keeping England neutral, sent Talleyrand to London. Talleyrand found public opinion there so far friendly that he wrote off to Paris, "Believe me, a *rapprochement* with England is no chimera." Pitt received him cordially; and to Grenville the envoy stated his hope that the two free nations would enter into close and friendly relations. Great Britain returned no definite answer, but Talleyrand was convinced that it would not intervene against France unless the latter attacked the Dutch Netherlands.

He returned to Paris on March 10, 1792, to persuade the foreign minister (Dumouriez now held that post) of the need of having a fully accredited ambassador at London. The ex-marquis Chauvelin was appointed, with Talleyrand as adviser. But the overthrow of the monarchy on Aug. 10 and the September massacres rendered hopeless all attempts at an *entente cordiale* between the two peoples; and the provocative actions of Chauvelin undid all the good accomplished by the tact and moderation of Talleyrand. The latter now sought to escape from France, where events were becoming intolerable; he landed in England on Sept. 23, avowedly on private business, but still animated by the hope of averting a rupture between the two governments. In this he failed. The provocative actions of the French Convention had brought the two nations to the brink of war, when the execution of Louis XVI (Jan. 21, 1793) made it inevitable. Talleyrand was expelled from British soil and made his way to the United States. There he spent thirty months in a state of growing uneasiness and discontent.

The Directory.—The course of events after the Thermidorian reaction of July 1794 favoured his return to France. Thanks to the efforts of Daunou and others his name was removed from the list of *émigrés*, and he set sail for Europe in November 1795. Landing at Hamburg in the January following, he spent some time there in the company of his friends Madame de Genlis and Reinhard and returned to Paris in Sept. 1796. He gained the post of foreign minister, entering on his duties in July 1797.

Talleyrand, despite the weakness of his own position (he was as yet little more than the chief clerk of his department), soon came to a good understanding with Bonaparte, and secretly expressed to him his satisfaction at the terms which the latter dictated at Campo Formio (Oct. 17, 1797). The *coup d'état* of Fructidor (September 1797) had perpetuated the Directory and led to the exclusion of the two "moderate" members, Carnot and Barthélémy; but Talleyrand saw that power belonged really to the general who had brought about the *coup d'état* in favour of the Jacobinical Directors headed by Barras.

With the renewal of war on the continent Talleyrand had little or no connection. His powers as minister were limited, and he regretted the extension of the area of war. Moreover, in the autumn of 1797 his reputation for political morality (never very bright) was overclouded by irregular dealings with the envoys of the United States sent to arrange a peaceful settlement of certain disputes with France. Talleyrand refused to clear himself of the charges made against him, and the incident probably told against his chances of admission into the Directory. A year later he resigned the portfolio for foreign affairs (July 20, 1799), probably because he foresaw the imminent collapse of the Directory. If so, his premonitions were correct. Their realization was assured by the return to France of the "Conqueror of the East" in October. The general and the diplomatist soon came to an understanding, and Talleyrand brought about the alliance between Bonaparte and Sieyès (*q.v.*) (then the most influential of the five Directors) which paved the way for the *coup d'état* of Brumaire.

Talleyrand's share in the actual events of the 18th, 19th Brumaire (9th, 10th of November) 1799 was limited to certain dealings with Barras on the former of those days. About midday he took to Barras a letter, penned by Roederer, requesting him to resign his post as Director; on that afternoon Barras left Paris. Talleyrand's reward for helping on the winning cause was the ministry for foreign affairs. In the great work of reconstruction of France now begun by the First Consul, Talleyrand played no unimportant part. His great aim was to bring about peace, both international and internal. After the battle of Marengo an Austrian envoy had to come to Paris in response to a proposal of Bonaparte, and Talleyrand persuaded him to sign terms of peace. These were indignantly repudiated at Vienna, but peace was made between the two Powers at Lunéville on Feb. 9, 1801.

As regards French affairs, Talleyrand used his influence to help on the repeal of the vexatious laws against *émigrés*, nonjuring priests, and the royalists of the west. He was also in full sympathy with the policy which led up to the signature of the Concordat of 1801–2 with the pope (*see* Concordat); but it is probable that he had a hand in the questionable intrigues which accompanied the closing parts of that complex and difficult negotiation. At the end of June 1802 the pope removed Talleyrand from the ban of excommunication and allowed him to revert to the secular state. On Sept. 10, 1803, owing to pressure put on him by Bonaparte, he married Madame Grand, a *divorcée* with whom he had long been living.

During the meeting of Italian notables at Lyons early in 1802 Talleyrand was serviceable in manipulating affairs in the way desired by Bonaparte, and it is known that the foreign minister suggested to them the desirability of appointing Bonaparte president of the Cisalpine Republic, which was thenceforth to be called the Italian Republic. In the negotiations for peace with England which went on at Amiens during the winter of 1801–2 Talleyrand had no direct share, these (like those at Lunéville) being transacted by Napoleon's eldest brother, Joseph Bonaparte (*q.v.*). On the other hand he helped the First Consul in assuring French supremacy in Switzerland, Italy and Germany. In Germany the indemnification of the princes who lost all their lands west of the Rhine was found by secularizing and absorbing the ecclesiastical states, and Talleyrand is known to have made large sums of money by trafficking with the claimants of church lands.

While helping to establish French supremacy in neighbouring states and assisting Bonaparte in securing the title of First Consul for life, Talleyrand sought all means of securing the permanent welfare of France. He worked hard to prevent the rupture of the peace of Amiens in May 1803, and he did what he could to prevent the sale of Louisiana to the United States earlier in the year. These events, as he saw, told against the best interests of France and endangered the gains which she had secured by war and diplomacy. Thereafter he strove to moderate Napoleon's ambition and to preserve the European system as far as possible. The charges of duplicity or treachery made against the foreign minister by Napoleon's apologists are nearly all unfounded. On assumption of the imperial title by Napoleon in 1804, Talleyrand became grand chamberlain of the empire.

The Empire.—Talleyrand had rarely succeeded in bending the will of the First Consul. He altogether failed to do so with the Emperor Napoleon. His efforts to induce his master to accord lenient terms to Austria in November 1805 were futile; and he looked on helplessly while that power was crushed, the Holy Roman empire swept away, and the Confederation of the Rhine set up in central Europe. In the negotiations with England which went on in the summer of 1806 Talleyrand had not a free hand; they came to nought, as did those with Russia which had led up to the signature of a Franco-Russian treaty at Paris by d'Oubril which was at once disavowed by the tsar. The war with Prussia and Russia was ended by the treaties of Tilsit (July 1807). Talleyrand had a hand only in the later developments of these negotiations.

Talleyrand had long been weary of serving a master whose policy he more and more disapproved, and after the return from Tilsit to Paris he resigned office. Nevertheless Napoleon retained him in the council and took him with him to the interview with the Emperor Alexander I. at Erfurt (September 1808). Talleyrand disapproved of the Spanish policy of Napoleon which culminated at Bayonne in May 1808; and the stories to the contrary may in all probability be dismissed as idle rumours. On Talleyrand now fell the disagreeable task of entertaining at his new mansion at Valençay, in Touraine, the Spanish princes virtually kidnapped at Bayonne by the emperor. They remained there until March 1814. At the close of 1808, while Napoleon was in Spain, Talleyrand entered into certain relations with his former rival Fouché (*q.v.*), which aroused the solicitude of the emperor and hastened his return to Paris. He subjected Talleyrand to violent reproaches, which the ex-minister bore with his usual ironical calm.

After the Danubian campaign of 1809 and the divorce of Josephine, Talleyrand used the influence which he still possessed in the imperial council on behalf of the choice of an Austrian consort for his master, for, like Metternich (who is said first to have mooted the proposal), he saw that this would safeguard the interests of the Habsburgs, whose influence he felt to be essential to the welfare of Europe. He continued quietly to observe the course of events during the disastrous years 1812–13; and even at the beginning of the Moscow campaign he summed up the situation in the words, "It is the beginning of the end." Early in 1814 he saw Napoleon for the last time; the emperor upbraided him with the words: "You are a coward, a traitor, a thief. You do not even believe in God. You have betrayed and deceived everybody. You would sell even your own father." Talleyrand listened unmoved, but afterwards sent in his resignation of his seat on the council. It was not accepted. He had no share in the negotiations of the congress of Châtillon in February–March 1814. On the surrender of Paris to the allies (March 30, 1814), the Emperor Alexander I. took up his abode at the hôtel Talleyrand, and there occurred the conference wherein the statesman persuaded the tsar that the return of the Bourbons was the only possible solution of the French problem, and that the principle of legitimacy alone would guarantee Europe against the aggrandizement of any one state or house. The tsar was convinced, and Talleyrand, on April 1, convened the French senate (only 64 members out of 140 attended), and that body pronounced that Napoleon had forfeited the crown. Ten days later the emperor recognized the inevitable and signed the Act of Abdication at Fontainebleau. The next effort of Talleyrand was to screen France under the principle of legitimacy and to prevent the schemes of partition on which some of the German statesmen were bent. Thanks mainly to the support of the tsar and of England these schemes were foiled; and France emerged from her disasters with frontiers which were practically those of 1792.

The Restoration.—At the congress of Vienna (1814–15) for the settlement of European affairs, Talleyrand, as the representative of the restored house of Bourbon in France, managed adroitly to break up the league of the Powers (framed at Chaumont in February 1814) and assisted in forming a secret alliance between England, Austria and France in order to prevent the complete absorption of Poland by Russia and of Saxony by Prussia. The new triple alliance had the effect of lessening the demands of those Powers and of leading to the well-known territorial compromise of 1815. Everything was brought into a state of uncertainty once more by the escape of Napoleon from Elba; but the events of the Hundred Days, in which Talleyrand had no share—he remained at Vienna until June 10—brought in the Bourbons once more; and Talleyrand's plea for a magnanimous treatment of France under Louis XVIII. once more prevailed in all important matters. On July 9, 1815, he became foreign minister and president of the council under Louis XVIII., but diplomatic and other difficulties led him to resign his appointment on Sept. 23, 1815, Louis, however, naming him high chamberlain and according him an annuity of 100,000 francs. The rest of his life calls for little notice except that at the time of the July Revolution of 1830, which unseated the elder branch of the Bourbons, he urged Louis Philippe, duke of Orleans (*q.v.*), to take the throne offered to him by popular acclaim. The new sovereign offered him the portfolio for foreign affairs; but Talleyrand signified his preference for the embassy in London. In that capacity he took an important part in the negotiations respecting the founding of the new kingdom of Belgium. In April, 1834 he crowned his diplomatic career by signing the treaty which brought together as allies France, Great Britain, Spain and Portugal; and in the autumn of that year he resigned his embassy. During his last days he signed a paper signifying his reconciliation with the Roman Catholic Church and his regret for many of his early actions. The king visited his death-bed. His death, on May 17, 1838, called forth widespread expressions of esteem for the statesman who had rendered such great and varied services to his country. He was buried at Valençay. He had been separated from the former Madame Grand in 1815 and left no heir.

The Talleyrand *Mémoires* were edited by the duc de Broglie in 5 vols. (Paris, 1891–92). They have been translated into English by A. Hall, 5 vols. (London, 1891–92). Of his letters and despatches the following are the chief collections:—G. Pallain, *La mission de Talleyrand à Londres en 1792* (Paris, 1889), and *Le ministère de Talleyrand sous le Directoire* (Paris, 1891); P. Bertrand, *Lettres inédites de Talleyrand à Napoléon*, 1800–09 (Paris, 1889); G. Pallain, *Talleyrand et Louis XVIII.* (Paris, 1881), and *Ambassade de Talleyrand à Londres* (1830–34), 2 vols. (Paris, 1891).

Among the biographies, or biographical notices, of Talleyrand the following are, on the whole, hostile to him: G. Touchard Lafosse, *Talleyrand, histoire politique et vie intime* (Paris, 1848); G. Michaud, *Hist. politique et privée de Talleyrand* (Paris, 1853); A. Pichot, *Souvenirs intimes sur Talleyrand* (Paris, 1870); Sainte-Beuve, "Talleyrand," in *Nouveaux lundis*, No. xii.; and Villemarest, *Talleyrand.* The estimate of him of Sir H. L. E. Bulwer Lytton in his *Historical Characters*, 2 vols. (London, 1867) and that of Lord Brougham in *Historical Sketches of Statesmen*, 3 vols. (London, 1845, new edition), are better balanced, but brief. Of recent biographies of Talleyrand the best are Lady Blennerhasset's *Talleyrand* (Berlin, 1894, Eng. translation by F. Clarke, 2 vols. London, 1894); *Talleyrand, a Biographical Study*, by Joseph McCabe (London, 1906); and Bernard de Lacombe, *La vie privée de Talleyrand* (1910); C. Dupuis, *Le Ministère de Talleyrand en 1814* (2 vols., 1919). (J. H. Ro.)

TALLIEN, JEAN LAMBERT (1767–1820), French revolutionary, was born in Paris in 1767. He entered a printer's office, and by 1791 he had reached the position of overseer of the printing department of the *Moniteur.* While thus employed he conceived the idea of the *journal-affiche*, and after the arrest of the king at Varennes in June 1791 he placarded a large printed sheet on all the walls of Paris twice a week, under the title of the *Ami des Citoyens, journal fraternel.*

This enterprise, financed by the Jacobin Club, made him well known to the revolutionary leaders; and he made himself still more conspicuous in organizing the great "Fête de la Liberté" on April 15, 1792, in honour of the released soldiers of Château-Vieux, with Collot d'Herbois. He was active in the events of Aug. 10, and was made clerk to the Revolutionary Commune of Paris. At the close of September he resigned his post on being elected a deputy to the Convention by the department of Seine-et-Oise. He took his seat upon the Mountain, and was one of the most vigorous Jacobins, particularly in his defence of Marat, on Feb. 26, 1793; he was elected a member of the Committee of General Security on Jan. 21, 1793. He took an active part in the *coups d'état* of May 31 and June 2, which resulted in the overthrow of the Girondists. On Sept. 23, 1793, he was sent with Claude Alexandre Ysabeau (1754–1831) to Bordeaux. This was the month in which the Terror was organized under the superintendence of the Committees of Public Safety and General Security.

Tallien showed himself one of the most vigorous of the proconsuls sent over France to establish the Terror in the provinces and soon awed the great city. Among his prisoners was Thérèse, the divorced wife of the comte de Fontenay, and daughter of the Spanish banker, François Cabarrus, one of the most fascinating women of her time, and Tallien not only spared her life but fell in love with her. Suspected of "Moderatism" on account of this incident, Tallien increased, in appearance, his revolutionary zeal, but from the lives Thérèse saved by her entreaties she received

the name of "Our Lady of Thermidor," after the 9th of Thermidor. Tallien was even elected president of the Convention on March 24, 1794. Robespierre began to see, however, that he must strike at his own colleagues in the committees if he was to carry out his theories; but they determined to strike first, and on the great day of Thermidor Tallien opened the attack upon Robespierre. Robespierre and his friends were guillotined; and Tallien, as the leading Thermidorian, was elected to the Committee of Public Safety. He suppressed the Revolutionary Tribunal and the Jacobin Club and fought bravely against the insurgents of Prairial. He was supported by Thérèse, whom he married on Dec. 26, 1794, and who became the leader of the social life of Paris. His last political achievement was in July 1795, when he was present with Hoche at the destruction of the army of the *émigrés* at Quiberon, and ordered the executions which followed.

Tallien's political importance came to an end with the Convention for, though he sat in the Council of Five Hundred, the moderates attacked him as terrorist, and the extreme party as a renegade. Madame Tallien also tired of him, and became the mistress of the rich banker Ouvrard. Bonaparte took him to Egypt in his great expedition of June 1798, and he edited the *Décade Egyptienne* in Cairo. But General J. F. Menou sent him away from Egypt, and he was captured by an English cruiser and taken to London, where he had a good reception among the Whigs and was well received by Fox. On returning to France in 1802 he obtained a divorce from his wife (who in 1805 married the comte de Caraman, later prince de Chimay), and was for some time without employment. At last he was appointed consul at Alicante, and remained there until he lost the sight of one eye from yellow fever. On returning to Paris he lived on his half-pay, and his latter days were spent in poverty. He died in Paris on Nov. 16, 1820.

Tallien left an interesting *Discours sur les causes qui ont produit la Révolution française* (1791) and a *Mémoire sur l'administration de l'Égypte à l'arrivée des Français. See* "Tallien et l'Expédition d'Égypte" in *La Révolution Française: Revue d'histoire moderne et contemporaine*, t. iii. p. 269. On Madame Tallien *see* Arsène Houssaye, *Notre Dame de Thermidor* (1866); J. Turquan, *Souveraines et grandes Dames: La citoyenne Tallien, témoignages des contemporains et documents inédits* (1898); and Louis Gastine, *La belle Tallien* (1909).

TALLINN, (Tallin, Reval), primary seaport and capital of Estonia, in 59° 26′ N., 24° 46′ E., on a bay in the south coast of the Gulf of Finland. Pop. (1959) 281,714. The port, frozen over about 45 days each winter, accommodates vessels drawing 30 ft. The chief exports are textiles, cereals, timber, paper and Portland cement, and the imports foodstuffs, cotton and coal. The town has textile, paper, cement and timber industries. The remains of the Toompea citadel (1539) and the ancient city wall with many of its towers make Tallinn picturesque. Many new buildings dominate the town, including a town hall. The Art Museum has a fine collection of modern Estonian painting and sculpture.

A Danish settlement on the high Silurian crag known as the Domberg existed in 1093, and the Danish king, Valdemar II, built a castle in 1219. It was captured by the Livonian knights in 1228, but returned to the Danes in 1237. Merchants from Lübeck and Bremen settled here in the 13th century, and it became a port of the Hanseatic league. It was fortified early in the 14th century and in 1343 sustained a siege by the revolted Estonians. Valdemar III sold Estonia to the Teutonic knights in 1346, but on the dissolution of the order, in 1561, Estonia and Reval surrendered to the Swedish king, Erik XIV. A great conflagration in 1433, the pestilence of 1532, the bombardment by the Danes in 1569, and the Russo-Livonian War destroyed its trade. The Russians besieged Reval in 1570 and 1577 and in 1710 it was surrendered to Peter the Great, who erected a port for his Baltic fleet. His successors continued to fortify the access to Reval from the sea, especially in the early years of the 19th century. It passed from Russian to Estonian rule in 1918, but fell to Russia in 1940, and to Germany in 1941. In World War II the shipping sections were heavily bombed.

TALLIS (Tallys, Talys or Tallisius), **THOMAS** (*c.* 1515–1585), justly styled "the father of English cathedral music," was born probably before 1515. It has been conjectured that, after singing as a chorister at old Saint Paul's under Thomas Mulliner, he obtained a place among the children of the chapel royal. He is known to have become organist at Waltham abbey, where, on the dissolution of the monastery in 1540, he received, in compensation for the loss of his preferment, 20s. for wages and 20s. for reward. In the library of the British Museum there is preserved a volume of ms. treatises on music, once belonging to the abbey, on the last page of which appears his autograph, "Thomas Tallys"—the only specimen known. Not long after his dismissal from Waltham, Tallis was appointed a gentleman of the chapel royal.

One of the earliest compositions by Tallis to which an approximate date can be assigned is the well-known *Service in the Dorian Mode*, consisting of the *Venite*, *Te Deum*, *Benedictus*, *Kyrie*, *Nicene Creed*, *Sanctus*, *Gloria in Excelsis*, *Magnificat* and *Nunc Dimittis*, for four voices, together with the *Preces*, *Responses*, *Paternoster* and *Litany*, for five, all published for the first time, in the Rev. John Barnard's *First Book of Selected Church Music*, in 1641, and reprinted, with the exception of the *Venite* and *Paternoster*, in Boyce's *Cathedral Music* in 1760. (Boyce's omission of the very beautiful *Venite* is hard to account for.) That this work was composed for the purpose of supplying a pressing need, after the publication of the second prayer-book of King Edward VI. in 1552, there can be no doubt. Written in the style known among Italian composers as *lo stile famigliare*, *i.e.*, in simple counterpoint of the first species, *nota contra notam*, with no attempt at learned complications of any kind, it adapts itself with equal dignity and clearness to the expression of the verbal text it is intended to illustrate. In self-restraint the *Litany* and *Responses* bear a close analogy to the *Improperia* and other similar works of Palestrina.

Tallis raised the English school to a height which it was to maintain until the death of its last representative, Orlando Gibbons, in 1625. Though this school is generally said to have been founded by Dr. Tye, there can be no doubt that Tallis was its greatest master, and that it was indebted to him alone for the infusion of new life and vigour which prevented it from degenerating, as some of the earlier Flemish schools had done, into a mere vehicle for the display of fruitless erudition. Like every other great musician of the period, he produced occasionally works confessedly intended for no more exalted purpose than the exhibition of his stupendous skill. In his canon *Miserere nostri* (given in Hawkins's *History of Music*) the intricacy of the contrapuntal devices seems little short of miraculous; yet the resulting harmony is smooth and normal, and only the irregular complexity of the rhythm betrays the artificiality of its structure. The famous forty-part motet, *Spem in alium*, written for eight five-part choirs, stands on a far higher plane, and the *tour de force* of handling freely and smoothly so many independent parts is the least remarkable of its qualities. It was edited by Dr. A. H. Mann in 1888 (London, Weekes and Company). (In the sixth volume of *Tudor Church Music* [Oxford University Press, 1928] all the forty parts are printed on one page.) The art with which the climaxes are built up shows that Tallis's object in writing for forty voices is indeed to produce an effect that could not be produced by thirty-nine. But this illustrates one phase only of Tallis's many-sided genius, which shines with equal brightness in the eight psalm tunes (one in each of the first eight modes) and unpretending little *Veni Creator*, printed in 1567 at the end of Archbishop Parker's *First Quinquagene of Metrical Psalms*.

In 1575 Tallis and his pupil William Byrd—as great a contrapuntist as himself—obtained from Queen Elizabeth royal letters patent granting them the exclusive right of printing music and ruling music-paper for twenty-one years; and, in virtue of this privilege, they issued, in the same year, a joint work, entitled *Cantiones quae ab argumento Sacrae vocantur, quinque et sex partium*, containing sixteen motets by Tallis and eighteen by Byrd, all of the highest degree of excellence. Some of these motets, adapted to English words, are now sung as anthems in the Anglican cathedral service. But no such translations appear to have been made during Tallis's lifetime; and there is strong

reason for believing that, though both he and Byrd outwardly conformed to the new religion, and composed music expressly for its use, they remained Catholics at heart.

Tallis's contributions to the *Cantiones Sacrae* were the last of his compositions published during his lifetime. He died on November 23, 1585, and was buried in the parish church at Greenwich, where a quaint rhymed epitaph, preserved by Strype, and reprinted by Burney and Hawkins, recorded the fact that he served in the chapel royal during the reigns of Henry VIII., Edward VI., Mary, and Elizabeth. This was destroyed with the old church about 1710; but a copy has since been substituted. Portraits, professedly authentic, of Tallis and Byrd, were engraved by Vandergucht in 1730 for Nicolas Haym's projected *History of Music*, but never published. One copy only is known to exist. A list of the printed and manuscript works of Tallis will be found in Grove's *Dictionary*.

TALLOW, the solid oil or fat of ruminant animals, but commercially obtained almost exclusively from oxen and sheep. *See* OILS, FATS AND WAXES.

TALLOW TREE, the common name of a small tree, *Sapium sebiferum*, family Euphorbiaceae, a native of China, but cultivated in other warm countries. The seeds are thickly coated with a white greasy substance—so-called vegetable tallow—from which candles are made, and which is also used in soapmaking and dressing cloth in parts of the orient. Elsewhere the tallow tree is used as a shade or ornamental tree. The butter tree or tallow tree of Sierra Leone is *Pentadesma butyracea*, family Guttiferae. The fruit, which is four to five inches long and about three inches in diameter, has a thick fleshy rind abounding in a yellow greasy juice which is used locally as butter.

TALLY. The wooden tally used in reckoning comes from two primitive notions; that of notching (scoring) a piece of wood for counting, as Robinson Crusoe did, and that of the broken stick shared between two parties to a bargain: the developed tally combines both. Use of this double tally, once prevalent all over Europe, is still frequent in the less advanced countries and not unknown in most. In England, though now nearly obsolete, it was exceedingly common mediaevally and its methods were highly developed; it endured long in certain connections; and its nomenclature survives in many words; to score at cricket (in Pickwick's day "to notch") derives from the single tally, and the verb "to tally" comes obviously from the double one; and other derivatives are many, if not quite so direct.

In England, however, the chief interest of the tally centres in its public use. This is earlier even than the very early "exchequer" organization (*see* EXCHEQUER); by a date not long after 1100 it was a settled system—a system, moreover, carefully differentiated from any private one and used for money only; and the tally continued to be the recognized form of receipt for payments into the Royal Treasury down to 1826. During this long period, though there were modifications of wording, it changed little outwardly save for a continually increasing length; the original 9 in. being extended in one extreme example which still survives at the Bank of England to 8 ft. 6 inches. This, however, is due solely to the increased number of thousands (notches of the thickness of a man's hand) which the tally might be required to show; and (apart from any difficulty due to the writing) a 13th century clerk could have interpreted it; the revolutionary changes lie, not in the tally's form, but in its employment.

The Assignment System.—At a very early date anticipation of the royal revenue became habitual and in this practice the tally was invaluable; nothing was easier than to "levy" a tally for a sum due for payment later and to "assign" this as payment to a royal creditor. Probably, at certain periods, creditors themselves had little objection to a practice which, in an age of difficult transport and clumsy currency, held many advantages. At the same time it might obviously lead to the lowering of royal credit and to endless confusion in accounts. Assignments were, in effect, payments; but tallies were essentially receipts; and as such, from the 13th century onwards, were all entered on "receipt rolls" and, later, figured in numerous supplementary series of records. Moreover an "assignment" tally frequently went wrong, and the mediaeval administrator could think of no better device than to substitute a fictitious "loan" on the roll, so as to square the account. The roll of "receipts" might thus include actual payments of cash, sums credited long before they were paid or due, and entries which indicate no payment at all, but rather a debt to be cleared later. The difficulties of the modern historian desiring to use these (exceedingly important) records, with none of the contemporary clerk's expert knowledge, needs no emphasis.

The Last Tally, 1826.—By Pepys' time tally-making at Westminster had become a ritual involving numerous officials, much delay and many fees, and from then onwards periodical attempts were made to destroy it. But vested interest successfully withstood reform till the 18th century; and it was not till 1826 that the last tally was levied and a system of "indented cheque receipts" substituted. A few years later (1834) reforming zeal celebrated its triumph by destroying (in the furnaces which heated the House of Lords) the whole accumulation of ancient tallies, with disastrous results; the old Houses of Parliament were burned and, incidentally (till the casual discovery in 1909, in the Chapel of the Pyx, of about 1,300 Exchequer tallies, practically all "stocks" of the 13th century), English historians were left without an essential clue to the understanding of some of the richest record series in the national collections.

See Hilary Jenkinson, "Tallies," *Archaeologia*, lxii (1911) and lxiv (1924). (H. JE.)

TALMA, FRANÇOIS JOSEPH (1763–1826), French actor, a rebel in politics and in art, was born in Paris on Jan. 16, 1763. He received part of his excellent education in England, where his father, a dentist, worked for several years. Although Talma practised dentistry after returning to Paris, he soon entered the School of Elocution for future *sociétaires* of the Comédie Française and made his debut at the famed theatre on Nov. 21, 1787, as Seide in Voltaire's *Mahomet*. Influenced by his friend the painter David, Talma became one of the early advocates of historical costuming when he appeared in a Roman toga and headdress in the small role of the tribune Proculus in Voltaire's *Brutus*. He found his great opportunity in Joseph Chénier's antimonarchical *Charles IX*, which not only provided him with an exciting role, acted with careful attention to psychological and historical detail, but also led him to challenge the monopoly of the aristocratic Comédie Française. The revolutionary sentiments of Chénier's play caused demonstrations in the theatre and aroused such dissension among the *sociétaires* that republican Talma established a rival troupe, known as the Théâtre de la République, on the site of the present Théâtre Français. There Talma developed realism in staging and costuming. When the two companies were reunited in 1799 at his theatre as the Comédie Française, Talma emerged the supreme tragedian of the era. Napoleon heaped honours on him; in 1808, for example, he had Talma perform at Erfurt before an audience of crowned heads. In both his scenic reforms and his acting, Talma was a leading precursor of 19th-century French romanticism and realism. He substituted intense emotionalism and realistic accuracy for the dignified repose of the French classical tradition. His artistic credo was "grandeur without pomp, nature without triviality." Talma died in Paris on Oct. 19, 1826.

Talma wrote *Reflections on the Actor's Art* as a preface to the *Memoires de Lekain* (1825). (H. K. CY.)

TALMUD (Heb. "learning"), a compilation that was revered by the Jews as a sacred book from the time it was compiled down to the 18th century, the laws expounded there being considered of divine origin on a par with those in the Torah (*see* PENTATEUCH). After the emergence of the *Haskalah* (Enlightenment) movement, and later upon the rise of the Reform movement, many Jews ceased to think of it as divinely inspired, regarding it nonetheless as of great value for the study of Jewish history, law, theology, folklore and ethics. A large segment of the Jewish population continues to regard the laws set forth in the Talmud as having been given by God, and the power of thought displayed in it by the Jewish sages of antiquity inspires profound respect in all students.

The Talmud comprises two main sections, the Mishnah and

the Gemara (the latter often called Talmud also), plus some additional laws called Baraitot and passages from another collection called Tosefta. The Mishnah ("repetition") is a lawbook, the production of the sages who lived in Palestine before the destruction of the Second Temple (A.D. 70) and a century and a half thereafter. The Gemara ("completion"), a commentary on the Mishnah, is the work of later sages, the *amoraim*. The Talmud deals, in the main, with legal matters, and this part is called *halaka* (pl. *halakot;* "law"); the nonlegal part is called *haggadah* ("saying," "narrative"). The *halakot,* the laws embodied in it, are based on Oral Law.

The Talmud is a storehouse of law, religion, history, ethics, metaphysical speculations, medical science, astronomy and folklore. It is an encyclopaedia covering every phase of human activity, a mine of information for the study of religion, history and civilization not only of the Jews but of the peoples of the entire middle east. It is important for a proper understanding of the origin of Christianity, since this literature came from men who taught at the time when Jesus lived. It is essential for a true comprehension of the controversies over the law between the Pharisees and Jesus as recorded in the Synoptic Gospels.

For the Jews the Talmud was not merely a lawbook, regulating life; its discussions, being divinely inspired, were the purpose and essence of life itself. When the Jews were persecuted and driven from public life during the middle ages, they found consolation in the study of the Talmud. It stimulated and cultivated their minds, saving them from stagnation. By its study they were assured of a reward in the future world, and this conviction was a religious incentive to every Jew. In the middle ages, when the great majority of the European population was illiterate, the Jews were saved from total ignorance by their intense devotion to the study of the Talmud.

ORAL LAW

Traditional Laws.—The Jewish people, like other peoples, in early times had unwritten as well as written laws. The written laws are those in the code called the Torah, the Pentateuch. But in the writings of the prophets as well as in the Hagiographa (*i.e.,* the Old Testament books exclusive of the Pentateuch and the Prophets) there are references to customs and laws that are not found in the Pentateuch. In the book of Jeremiah, for example, it is stated that when the prophet bought a field from Hanamel he wrote a deed in the presence of witnesses who affixed their signatures. There is no mention in the Pentateuch of the requirement of a deed and witnesses in the transfer of real property. In the book of Ruth it is said that Boaz told his kinsman that he would have to marry Ruth when he purchased the field from Naomi "in order to restore the name of the dead to his inheritance" (iv, 5). It is further stated that this was the custom "in former times in Israel concerning redeeming and exchanging: to confirm a transaction, the one drew off his sandal and gave it to the other, and this was the manner of attesting in Israel." This custom of transferring immovable property by the symbolic act of drawing off the shoe is not mentioned in the Pentateuch.

In ancient times, if a man did not pay his debts, his creditor had the right to take him into servitude; if he died and left the debt unpaid, the creditor could enslave his children. This is shown by a passage in II Kings (iv, 1) in which a woman cries to Elisha, "'Your servant my husband is dead; and you know that your servant feared the Lord, but the creditor has come to take my two children to be his slaves.'" This law is not mentioned in the Pentateuch.

It is evident from the book of Genesis that among the early Hebrews a man had to purchase his wife from her father. Jacob paid Laban in manual labour for the right to marry his daughters; David paid Saul 200 foreskins of the Philistines for the right to marry his daughter Michal. Yet the Pentateuch makes no reference to bride price. Nor is any writ in connection with marriage referred to in the Bible; nonetheless a custom of writing marriage documents prevailed among the early Hebrews. Such a document is recorded in the Elephantine papyri. Also, in the book of Tobit, it is said that when Raguel gave his daughter Sarah to Tobias he called her mother, "took a scroll and wrote out the contract; and they set their seals to it" (vii, 14).

The unwritten laws were as old as, and perhaps older than, some of those embodied in the Pentateuch. The sages of the Talmud recognized this when they said that thousands of laws or customs were forgotten during the time of mourning for Moses. Such nonpentateuchal laws came to be known as *halakot, torah shebe-al pe,* "Oral Law," while the laws of the Pentateuch were described as *torah shebikthab,* "written laws."

The unwritten law has been considered holy by all peoples. Sophocles made Antigone justify the burying of Polynices, against the order of King Creon, on the basis of "the immutable unwritten laws of god. They were not born today nor yesterday; they die not; and none knoweth whence they sprang." Aristotle spoke of written and unwritten laws, the latter of which were based upon nature and universally recognized. Philo, in his *Special Laws,* wrote, "For customs are unwritten laws, the decisions approved by men of old, not inscribed on monuments nor on leaves of paper which the moth destroys, but on the souls of those who are partners in the same citizenship." He differentiated between written and unwritten laws, stating, "Praise cannot be duly given to one who obeys the written laws, since he acts under admonition of restraint and the fear of punishment. But he who faithfully observes the unwritten deserves commendation, since the virtue which he displays is purely willed." Aristotle reflected a similar opinion in the *Rhetoric.*

Pharisees and Sadducees.—According to Josephus, who is upheld by the tannaitic literature, the Sadducees denied the authority of the Oral Law while the Pharisees adhered to it. But the Sadducees could not reject all the laws that were not mentioned in the Pentateuch, since no state can function without custom. The cleavage between the Pharisees and the Sadducees was due to the fact that the former maintained that the Oral Laws were as binding as the written laws and that transgressors of the unwritten laws should be punished as were those who transgressed the written laws. The Sadducees denied this, on the ground that the unwritten laws were less binding than the pentateuchal laws. The Pharisees also maintained that the pentateuchal laws must be amended and interpreted so as to conform to the changing culture and economic condition of the people; the Sadducees rejected such innovations. (*See* JEWISH SECTS DURING THE SECOND COMMONWEALTH: *Pharisees; Sadducees.*)

Revisions and New Laws.—In the course of time, however, all laws, written and unwritten, become outmoded. Some device or institution is needed to provide for amendment and interpretation in order to bring them into consonance with contemporary life. In the Jewish second commonwealth period such an institution was developed—the Sanhedrin (*q.v.*).

Before the Hasmonaean period the Jewish government was a theocracy. Religious authority was vested in the high priest, the representative of God. Theocracy was abolished after the establishment of the commonwealth, and nomocracy (the rule of the law) was instituted in its stead. A *bet din* ("court"), commonly known as Sanhedrin, was inaugurated in 141 B.C., with authority to interpret the pentateuchal laws and to enact the unwritten laws into statutory laws. Further, new laws were added by the *sopherim,* "scribes," of the Sanhedrin (*see* SCRIBES). Rabbi Joshua said that certain new laws were introduced by the *sopherim,* "and I cannot gainsay them" (*Tebul Yoṁ* 4, 6). The *sopherim* also modified the pentateuchal laws, holding that their modifications were in the tradition of the fathers. They amended, for example, the pentateuchal law concerning levitical purity. According to the Pentateuch, ritual cleansing could not be completed till after sunset. In later times this worked great hardship on the people, interfering with their daily lives. The sages therefore declared that the law applied only to priests in the matter of eating the sacred food. But the requisite of washing the whole body still worked hardship, so the sages reduced it to a mere washing of the hands before meals. Reference to this law is made in the Synoptic Gospels, where it is described as the "tradition of the elders."

It is stated in the Pentateuch that a Jew may not carry a burden on the sabbath, but Oral Law specified that things may be carried

in the house. According to the Pentateuch cattle must be slaughtered before their flesh is eaten, but the method of slaughtering is not described; the Oral Law defines ritualistic slaughter as cutting the throat.

In some cases Oral Law took precedence over the written law or even nullified it. The Pentateuch states that the blood of a fowl should be covered with sand, but according to the Oral Law it may be covered with anything that happens to be at hand. The sages took cognizance of the fact that the Oral Law expresses the spirit of the law, namely that the blood be covered.

Civil Law.—Civil as well as religious laws in the Pentateuch are so ambiguous and narrow that no civilized society could have been governed without the Oral Law, which supplemented and interpreted the pentateuchal laws, making them adaptable to changing conditions and expressive of the evolving views of society. There are laws in the Pentateuch regarding damages and injury, but there are no specifications of gradations in torts, injuries and liabilities. No law is given regarding damages that are not discernible. For example, a person might mix another person's wheat with "sacred wheat," making it impossible for the second man to use it and thus causing a financial loss; yet the damage was not recognizable in pentateuchal law. According to the Oral Law, however, the person committing this act was obligated to pay for the damages he caused.

The laws of partnership, of the means of acquiring property and of personal agency are not dealt with in the Pentateuch but are based on Oral Law. The pentateuchal laws dealing with inheritance, for example, assumed the inalienability of bonded property from the possession of the tribe. When a person dies his estate is inherited by his sons; where there are no sons it passes to his daughters, and where there are no daughters it goes to the nearest kin. It must always remain in the family of the tribe. The idea of testament is not found in the Pentateuch for the simple reason that the Pentateuch does not recognize that property may be transferred to a stranger. The Oral Law took cognizance of changed sociological conditions and gave a person the right to write a will devising part of his property to anyone, even to a stranger. According to the Oral Law, man is immortal but the title to property is limitable by time. A man may stipulate that his will take effect after his death and the court is obligated to carry out his bequest.

No reference is made in the Pentateuch to writs, whether in connection with property transactions or loans. It is clear from papyri that as early as the 5th century B.C. a debtor gave his creditor a note in which he not only obligated himself to pay the debt but also gave the creditor the right to seize his property if the debt was not paid; if the debtor died before the loan was paid, his children had to pay it. The right of seizure of a debtor's property was based on the unwritten law, and the promissory note nullified the biblical laws that gave the creditor rights over the person of the debtor and his children.

Use of promissory notes also modified the pentateuchal law in connection with the sabbatical year. The Pentateuch clearly specifies that a debt that outlasts the sabbatical year can no longer be collected. To encourage loans to the needy, Hillel introduced the *prosbul* (derived from the Greek *pros boule*, "before the council"), in which the creditor deposited with the court a note stating that a debt owed him by A might be collected at any time the creditor chose. The creditor thus secured his debt against the provision of the pentateuchal law concerning the sabbatical year. A loan for which no note was given was forfeited if not paid before the year of release.

The Pentateuch refers twice to the *lex talionis*, an eye for an eye, a tooth for a tooth (Ex. xxi. 24; Lev. xxiv. 20), but injury and bodily mutilation as well as theft were considered private wrongs. It was not for the state to punish the offender; the matter was to be settled between the person who inflicted the injury and the one injured. The man who suffered the loss of an eye or any other member of his body could absolve entirely the man who caused the injury or could demand any satisfaction, even to taking out the eye of the man who caused the loss of his eye. *Talio* was the extreme satisfaction the plaintiff might demand, but it was not mandatory; the injured person could obtain satisfaction with money if he so wished. On the principle that two different persons could not have exactly the same members of the body, the sages enacted a law by which the injured man could not demand an eye from the person who caused the loss of his eye but that he could demand the value of his eye. In this way, the *lex talionis* was abolished.

Shammaites and Hillelites.—The sages of the commonwealth endeavoured not only to interpret the pentateuchal laws so as to bring them into consonance with contemporary life but also to incorporate some of the old *halakot* into statutory laws—in other words, to make them written laws in order that they might be used as a basis for deducing new laws in accord with the demands of the times. Two schools of thought arose in regard to the soundness and the validity of interpreting the pentateuchal laws and the *halakot*. One, the Shammaites, represented the conservative, the other, the Hillelites, the liberal point of view. They were named after the great sages Shammai and Hillel (*qq.v.*), the fifth and last of the *zugot* ("pairs"), or joint heads of the Sanhedrin. Every sage enrolled himself as a Shammaite or as a Hillelite, and the two schools, which arose with the establishment of the commonwealth, continued until the time of the compilation of the Mishnah.

To establish a legal system by which the pentateuchal laws could be interpreted, and to legalize the modification, Hillel applied three hermeneutic devices. These are (1) *kal wa-homer*, inference *a minori ad maius*, from the less important (law) to the more important (law); (2) *gezerah shawah*, inference by analogy of words; and (3) *hikish*, inference by analogy of subjects. These three principles were not introduced by Hillel, but it was he who organized them into a juristic discipline by which the entire pentateuchal law could be interpreted. Later the three were developed into seven, and Rabbi Ishmael, who lived after the destruction of the Second Temple, increased them to 13. In accepting the hermeneutics as a legal system the sages found it necessary to limit them in certain ways. In regard to penal law, for example, the inference from *minori ad maius* could not be applied; no penalty could be inflicted that was based upon an inference. Again, the principle of inference could not be made from a *halaka;* it was applicable only to the laws of Scriptures and to those *halakot* that had become statutory.

The method of interpretation of the pentateuchal laws was called Midrash Mikra and that of interpretation of the old *halakot* was called Midrash Halakot. The sages who interpreted the pentateuchal laws were called *darshanim*, "interpreters," and the place where they assembled was known as the Bet ha-Midrash.

The idea of intention as a legal principle was the great innovation introduced by Hillel. An act without intention, although willed, was not considered a legal act. For example, if a man gives a ring or money to a woman, this does not make her his wife. The consummation of a marriage requires intention. The man has to give the ring to the woman with the intention of marrying her by open declaration. Hence, according to talmudic law, marriages of minors and lunatics are invalid, since such persons cannot exercise intention. The principle of intention had a far-reaching influence on all Jewish laws, ritual, civil and criminal. Shammai and his school strongly opposed this innovation, but it became an integral part of the legal system of the Talmud.

***Rabbon* and *Tanna*.**—With the liberal views of Hillel prevailing among the sages, there came a change in the leadership of the Sanhedrin. Previously two men had headed this institution, the *nasi* and the *ab bet din*. The office of the latter was now abolished. Gamaliel (*q.v.*), grandson of Hillel, became the sole leader of the Sanhedrin, with the title *rabbon*, "our *nasi*" (*rabba* is the Aramaic form of *nasi*). The sages who interpreted the law were called *sopherim*, "scribes," before the destruction of the Second Temple, and this term occurs in the Gospels; no title was appended to their names. After the destruction of the Temple the sages came to be called *tannaim*, and those who received authorization had the title rabbi.

The *tannaim* were jurists, as is exemplified in the *halakot* with regard to *jus in personam* and *jus in rem*. They held that the law

was made for man and not man for the law. They maintained that society cannot be governed without law, and that the purpose of law is to prevent men from doing what is wrong and to punish violators. They held however that equity should be applied to decisions and leniency should take precedence over strictness in the application of the law. The *tannaim*, who were the spiritual leaders of the people, aimed to promote the general welfare by regulating the relations between man and God and between man and man.

THE MISHNAH

After the destruction of Jerusalem by the Romans in A.D. 70, Jabneh (modern Jamnia, located on the Judaean plain of western Israel) became the centre of Jewish learning. With the collapse in A.D. 135 of the Bar-Cochba revolt, which led to the virtual decimation of the Judaean population, the centre was moved to Usha in Galilee (near modern Haifa). During this momentous period in the history of the Jews the sages decided that the *halakot* should be assembled and codified. There was disagreement as to how the collection should be organized, one school holding that the *halakot* should be collected in the order of the biblical verses from which they were interpreted, the other maintaining that they should be arranged according to the subject matter. The view of the latter school prevailed, and the assembling of the *halakot* on this plan, begun by Rabbi Akiba, was continued by his disciples (especially Meir) and completed in the early part of the 3rd century A.D. by Rabbi Judah ha-Nasi, the Prince, known as rabbi par excellence. This collection of the *halakot* was called Mishnah (Gr. Deuterosis), second to the Torah (the word is variously transliterated also as Mishne and Mishna). Soon after its completion it became the standard work for further interpretations of the *halakot* and was revered as second only to the Bible. The halakic decisions in the Mishnah became binding.

Orders of the Mishnah.—The Mishnah is divided into six "orders" (*sedarim*), each order into tractates (*masechot*) and each tractate into chapters (*perakim*). The *sedarim* are as follows:

1. *Zeraim* ("seeds"), 11 tractates. The first tractate, called *Berachot*, deals with worship and treats of benedictions and prayers and the time of the reading of the *shema*. In other tractates the biblical precepts are set forth relating to the rights of the poor, tithes given to the priests and the Levites, rules and regulations connected with agriculture and the laws connected with the sabbatical year.

2. *Moed* ("festivals"), 12 tractates. In this order the laws in connection with the sabbath and the festivals are set forth. One tractate is devoted to the laws connected with fasts. Another, *Shekalim*, treats of the half-shekel which every Jew had to contribute to the Temple.

3. *Nashim* ("women"), 7 tractates. This order deals with the laws of marriage and divorce and Levirate marriage and divorce. Also given are the regulations governing the relations between husband and wife and between the sexes in general. In this order the tractate *Nedarim* treats of vows and their annulment. Another tractate, *Nazir*, gives the laws concerning Nazirites.

4. *Nezikin* ("damages"), 10 tractates. The first tractate, called *Nezikin*, is divided into three parts: *Baba Kama* ("first gate"), in which the laws of damages and injuries and those regarding theft and robbery are set forth; *Baba Metzia* ("middle gate"), which treats of laws concerning found property, usury and hired labour; and *Baba Bathra* ("last gate"), which deals with *hazakah* (usucapion), the laws regarding the sale and purchase of immovable and movable property, and the laws of partnership and inheritance. *Sanhedrin* ("court") concerns the composition of the court and trial procedure, with the different punishments for various offenses, with the principle of corpus delicti and with the laws of arbitration. *Makkoth* ("stripes") deals with the lashings to which a person is condemned by a court. *Shebuoth* ("oaths") treats of the different kinds of oaths, those made in private life and those administered in court. *Aboda Zara* ("idolatry") treats of the laws concerning idols and the relation to idol worshipers. Two other tractates that bear no relation to the main subjects are included in this order: *Eduioth* ("testimonies"), a collection of traditional laws; and *Aboth* ("fathers"), a collection of ethical maxims of the sages.

5. *Kodashim* ("holy things"), 11 tractates. This order, devoted to the subject of sacrifices, contains the tractates *Tammid* ("daily sacrifice") and *Middoth* ("measurements"), which describe the daily sacrifices of the morning and of the evening, and of the area of the Temple, its courts, gates and the daily services of the priests and the Levites.

6. *Toharoth* ("purifications"), 12 tractates. It sets forth the laws of ritual cleanliness and uncleanliness, both in persons and in things, and the laws in connection with purifications. The tractate *Yadayim* ("hands") is devoted to the laws in connection with the ritual impurity of the hands, their defilement of the Holy Scriptures. In this tractate is related the controversy in regard to the canonicity of Ecclesiastes and the Songs of Solomon.

Character of the Mishnah.—The Mishnah is a code of *halakot* consisting of religious laws and laws governing society. These *halakot* in general are not based on the Pentateuch; biblical texts are not quoted to substantiate the *halakot*. In *Baba Bathra*, which consists of ten chapters dealing with civil law, there is not a single reference to the Bible. References are made to biblical verses only in some chapters of a few tractates, and this practice can be traced to the Midrash form applied by many sages in interpretation of *halakot*.

Two orders—*Kodashim*, which treats of sacrifices, and *Toharoth*, which sets forth the laws of ritual cleanliness and uncleanliness—are concerned with matters that had become obsolete. They were included in the Mishnah because, first, many of the tractates had already been compiled before Rabbi Judah's time, and, second, the Jews of the period had complete confidence that before long the Temple would be rebuilt and sacrifices restored.

The Mishnah, because of the fact that the tractates were compiled at various different times, shows a lack of consistency. The unevenness of the Hebrew language also can be attributed to the fact that it represents many periods of antiquity and of post-Hadrianic times. The sequence of many tractates within each order is of a later era and is mechanical. Rabbi Judah did not set the sequence.

The Mishnah, being a code, does not contain *haggadoth*, legends such as occur in the tannaitic literature and in the Talmud (*see* below, *The Talmuds*). Messianic and eschatological ideas that were prevalent among the Jews of the time of its compilation are largely ignored. It is stated that those who do not believe in the Revelation and those who deny resurrection (spiritual) will not share in the future world. No mention is made of those who deny the coming of the Messiah. No reaction may be seen in the Mishnah toward the Christians in general, or, with one exception, toward the Jewish Christians. In the tractate *Berachot* it is stated that, by law, when a Jew greets another Jew he should pronounce the Name, the Tetragrammaton, although pronouncing the name of God is prohibited in the Pentateuch (*e.g.*, Ex. xx, 7, "You shall not take the name of the Lord your God in vain"). Jewish Christians, on meeting their fellow Christians, greeted them, "Peace in the name of God and the Lord Jesus Christ." The sages, disregarding the injunction of the Pentateuch, introduced a law requiring pronunciation of the Tetragrammaton in order to signify that there is one Lord and that he is God, and that Jesus was not the Messiah; furthermore, this greeting would reveal believers in Jesus.

It may be asked, if the Mishnah is a corpus juris, why does it contain divergent opinions in connection with the laws? The answer is that Rabbi Judah believed that the opinions of the minority as well as of the majority should be recorded, even though the decision of the law had to follow the majority opinion. The minority opinion was included so that if at some future time new laws were enacted the rabbis would be able to find support for their decisions in these minority opinions. When Judah thought that the decision of the law should follow the opinion of one particular sage he recorded his opinion anonymously or in the name of the sages; *i.e.*, he stated it as a majority opinion. Other principles were laid down regarding decisions of the law; for example, when there was a controversy between the schools of Shammai and Hillel, the law was decided in accordance with the latter.

The Mishnah, though a code, cannot be compared to the Pentateuch, which was believed to be revealed by God to Moses and had to be administered by a high priest, a vicar of God. Nor can it be compared to the code of the Roman law—the sages did not derive their authority from secular rulers or magistrates. Their authority was based rather on their profound knowledge of the law and ability to interpret it, and on the authorization received from their spiritual mentors, which, according to tradition, came down unbroken from Moses.

Writing of the Mishnah.—A divergence of opinion exists with regard to the compilation of the Mishnah. Many rabbis of the middle ages, particularly of Spain, followed by many modern scholars, maintained (and maintain) that neither the Mishnah nor the *halakot* were committed to writing until the 6th century A.D. and that the Mishnah was organized only orally by Rabbi Judah. On the other hand, many medieval rabbis, particularly of France and Germany, supported by many other modern scholars, were (and are) of the opinion that the Mishnah was committed to writing by Judah. It can be deduced from internal evidence not only that the Mishnah was written by Judah but that many *halakot* had been put in writing long before his time. The injunction against the writing of *torah shebe-al pe* (the unwritten law) refers only to the customs and the oral laws that had not yet been made statutory.

Great *Tannaim*.—Among the *tannaim* responsible for the shaping of the *halakot*, two disciples of Rabbon Johanan ben Zakkai deserve particular mention: Rabbi Eliezer and Rabbi Joshua. Another sage was Rabbon Gamaliel, the grandfather of Rabbi Judah ha-Nasi, the successor of Johanan ben Zakkai as head of the academy of Jabneh and chiefly responsible for the organization of the *halakot*. Rabbi Akiba by his great intellect and acumen had great influence in the shaping of the *halakot*. He introduced new methods of interpretation of the Bible for the purpose of enacting new laws. He laid the groundwork for the compilation of the Mishnah that was accomplished later by Judah. His dialectic methods are recognized in the halakic discussions of his disciples, particularly those of Simon, Judah, Jose and Meir. The last had the keenest legal mind. To this group must be added Rabbi Simon ben Gamaliel, the father of Judah ha-Nasi, who headed the academy at Usha. These are only a few of the *tannaim* who flourished after the destruction of the Second Temple. The tannaitic period ended with the compilation of the Mishnah.

THE TANNAITIC LITERATURE

Midrash Mikra.—There are other collections of laws, the works of the sages who maintained that the *halakot* should be arranged according to the sequence of the pentateuchal passages. They are: (1) *Sifra* ("the book" par excellence), in which the *halakot* are arranged in the order of the passages in the book of Leviticus; and (2) *Sifre* ("the books"), in which the *halakot* are arranged in the order of the passages in the books of Exodus, Numbers and Deuteronomy. These collections are called Midrash Mikra. (*See* also MIDRASH.)

Tosefta and Baraitot.—Rabbi Judah collected *halakot* that he felt should be recorded in the Mishnah as a way of life for the Jews. He did not include those which at that time were out of date due to social and religious changes that had occurred in the life of the Jews. For example, the laws of impurity, held by the sages to be inapplicable to the pagans, had become obsolete after the destruction of the Second Temple, since pagans were now considered human beings like the Jews and the laws of impurity became applicable to them; likewise, the law that a woman can be among the seven called to the Torah was omitted, since at this time women were already segregated in the synagogues. Rabbi Judah's disciple Rabbi Hiyya made a collection, called Tosefta, of those *halakot* that were not recorded in the Mishnah. The sequence and the arrangement of the orders of the tractates in the Tosefta are similar to those in the Mishnah; three tractates—*Aboth*, *Middoth* and *Tammid*—were omitted since they did not contain *halakot*.

There are notable differences between the Mishnah and the Tosefta. In the Mishnah eschatological ideas are not recorded and there are no references to reward for the righteous and punishment for the wicked after death. The Tosefta, on the other hand, deals with these speculations, and it states that wicked Jews and wicked pagans will be judged in Gehenna for 12 months as a kind of purgatory. However the Jewish apostates and informers would never be released from punishment. Righteous pagans would share a portion in the future world, and thus were placed in the same category as Jews. None of this, not even the word Gehenna, is found in the Mishnah.

During the second commonwealth the Pharisees were inimical toward the apocalyptists, who were occupied with esoteric doctrines and metaphysical ideas and believed in a supernatural Messiah and a physical resurrection. The apocalyptists became influential after the conquest of Jerusalem by the Romans; some accepted Christianity while others infiltrated the ranks of the Jewish people. The *tannaim*, heirs of the Pharisees, continued their opposition, which is revealed in a story related in the Tosefta: Four men—Simon ben Azzai, Simon ben Zoma, Elisha ben Abuya and Rabbi Akiba—went into *pardes* ("paradise") and steeped themselves in mystic and esoteric philosophy. Only Akiba emerged without impairment to his faith or detriment to his intellect. Simon ben Azzai met with an untimely death, Simon ben Zoma became demented, and Elisha ben Abuya turned apostate.

The opposition of the *tannaim* toward apocalyptic doctrines was unsuccessful; indeed some of the *tannaim* themselves resorted to such speculations. Their strictures against superstition did not deter some *amoraim* from adopting these beliefs. Under the stress of personal misfortune and national calamity, people tend to seek solace in superstition and mysticism, and such has been the inclination of many Jews throughout the ages. Medieval Cabala (*q.v.*) was an outgrowth of apocalyptism, and many rabbis of the middle ages regarded Cabala as a menace to true Judaism, as their predecessors, the *tannaim*, had regarded apocalyptism. (*See* also APOCALYPTIC LITERATURE.)

A story in the Tosefta illustrates the endeavours of the followers of Jesus to convert the Jews to belief in him as the true Messiah, and also the disposition of the *tannaim* toward the Jewish Christians. It concerns a nephew of Rabbi Ishmael, Eliezer, who was bitten by a serpent. A certain Jacob sought to heal him in the name of Jesus, son of Panthera. Rabbi Ishmael forbade Eliezer to accept the ministrations of Jacob, and though Eliezer died, yet Rabbi Ishmael exulted, because his nephew had not succumbed to the Christian faith. The story led the 3rd-century Christian writer Origen, in his treatise against the pagan Celsus, to accuse the Jews of spreading false tales regarding the genealogy of Jesus by maintaining that he was the son of Panthera.

A number of additional *halakot* not included in the Tosefta but found in the Talmud are laws of the tannaitic period called Baraitot (sing. Baraita; from a word meaning "outside," thus *halakot* outside the Mishnah). The Tosefta and the Baraitot, since they contain *halakot* that were already obsolete at the time of compilation of the Mishnah, as well as other *halakot* that arose afterward, are more important than the Mishnah itself for the history of the religious and social life of the Jews. The use of Roman legal terms in the Tosefta and Baraitot shows the influence of Roman law on the tannaitic *halakot*.

Both the Tosefta and the Baraitot in some respects differ from the Mishnah. The latter, since it is a code, presents the laws in a legal form. The others are more informal, and in the Tosefta some laws are illustrated by parables. For example, a law which states that the owner of a field must not throw stones from the field onto public property is illustrated in the Tosefta by a story that stresses the moral. Once a proprietor in clearing a field threw the stones onto the public road. A pious man, observing this, told the owner that he was really throwing stones onto his own property. Subsequently the owner, for economic reasons, was compelled to sell his field. Walking on the road where he had thrown the stones he stumbled on them and was injured.

THE TALMUDS

The Mishnah attained canonical authority soon after its completion. The sages and teachers who expounded it were called

amoraim, and the work that resulted from their endeavours was the Gemara, known as the Talmud. The Gemara constitutes both a commentary on and an interpretation of the Mishnah. There are two Gemaras—the Palestinian (*Talmud Yerushalmi*), written in Western Aramaic and replete with many Greek and Latin terms and expressions; and the Babylonian (*Talmud Babli*), written in the Eastern Aramaic dialect and sprinkled with Persian words. The Babylonian Talmud or Gemara is often called the Talmud.

Contents.—The Palestinian Gemara consists of 39 tractates: the entire orders of *Zeraim*, *Moed*, *Nashim* and *Nezikin* (with the exception of *Eduioth* and *Aboth*); and a section of the tractate *Niddah* of the order *Toharoth*. It contains none of the tractates of the order *Kodashim*.

The Babylonian Gemara consists of 37 tractates: one tractate, *Berachot*, of the order *Zeraim;* all of the order *Moed* except the tractate *Shekalim;* all of the order *Nashim;* all of *Nezikin* except *Eduioth* and *Aboth;* all of *Kodashim* except the tractates *Middoth* and *Kinnim;* none of the order *Toharoth* except *Niddah*.

The reason for the omissions is not known; perhaps they were lost. Although the Palestinian Talmud contains more tractates than the Babylonian, the latter is much fuller and larger.

Talmudic Academies.—The disciples of Judah ha-Nasi took up the study of the Mishnah after his death. Tiberias became the centre of Jewish learning, but there were other *yeshibot*, or academies, in Caesarea and Acco. The talmudic academies in Palestine soon fell into decay because of political and economic conditions. The Palestinian Jews at first were under the yoke of the Roman despotism. Later, when Christianity became the dominant religion of Rome, their condition worsened. They were not even allowed to communicate with their coreligionists in Babylonia and were compelled to employ a code to notify them of the intercalations of the year. By the end of the 4th century all of the academies in Palestine had ceased to exist and the compilation of the Palestinian Talmud came to an abrupt end.

Abba Arika, known as Rab, and Mar Samuel, disciples of Judah ha-Nasi, returned to Babylonia, their native land, after the death of their master, and Mar Samuel became the head of the *yeshiba* in Nehardea on the Euphrates. After that city was sacked by the Palmyrians a *yeshiba* was organized at Sura, headed by Rab (A.D. 219). Rab Judah ben Ezekiel, a disciple of Samuel, in 247 organized the great *yeshiba* in Pumbeditha which lasted more than seven centuries. These two *yeshibot* became the leading centres of Jewish learning. The *yeshiba* of Pumbeditha was noted for the keen dialectics employed in the halakic discussions, particularly prominent in which were Judah ben Ezekiel, Rabbah bar Nahmani and his nephew Abaye and his colleague Rabba. Their discourse at times soared into the realm of the incomprehensible.

In the *yeshibot* the studies were designed for those persons, called *haberim*, who devoted their lives to research in the *halakot*. Sessions were also organized, however, to disseminate knowledge among laymen. There was a maxim among the *tannaim*, adhered to by the *amoraim*, that knowledge is superior to observance. These sessions were held in the spring in the month of Adar (March) and in the autumn in Elul (September), and the laity came to the *yeshibot* and participated in talmudic discussions.

Authors.—All the *amoraim* contributed to the Talmuds, but the chief architect of the Palestinian Talmud (compilation of which ceased late in the 4th century) was Johanan bar Napacha, while the Babylonian Talmud was chiefly compiled by Rabbi Ashi (*q.v.*), the head of Sura academy in the early part of the 5th century A.D. It was completed by Rabina *c.* 499.

The *saboraim* ("those who reflect"), who flourished in the 6th and the first part of the 7th century, explained the terminology and interpreted many passages. They also established rules to help in the understanding of the Talmud. Their interpretations and explanations became a part of the work. While some of their interpretations help in the understanding of intricate passages, others lead to confusion. It is difficult to know what passages came from the *amoraim* and what passages were interpolated by the *saboraim*, since no early manuscripts exist. The work of the *saboraim* on the Talmud was later carried on by the *geonim* (*see* GAON).

The Babylonian Talmud became the standard text of Jewish law and religion. It was considered divine. The *halakot* in the Talmud were authoritative; no rabbi could differ from them, he could only interpret. However, the *geonim* conceded that *haggadah* was not authoritative.

Character of the Talmud.—The Talmud consists of *halaka* and *haggadah* (Aramaic *agada*, "legend" or "narrative"), the former being far more numerous. The *amoraim* used the same method in their interpretation of the Mishnah as the *tannaim* had in their interpretation of the Holy Scriptures. They employed exegetical principles in elucidating the *halakot* and expressions in the Mishnah. Where there was tautology of words or expressions, the *amoraim* used them as basis for the deduction of new *halakot*. When there was a clash between two tannaitic principles, the *amoraim*, in their endeavour to harmonize conflicting opinions, introduced a new law.

Halakot.—The *halakot* of the Babylonian Talmud are the production of sages who lived in the Diaspora. This is reflected in the many laws that had to be adjusted to the life of Jews who no longer had their own state and government. Mar Samuel in 219 introduced a law that was far reaching in the life of the Jews throughout the ages—that the civil laws of the country were binding on the Jews. Many *halakot* reveal the influence of the laws of the country in which the Jews lived: the Palestinian Talmud reveals a marked influence of the Roman law, whereas in the Babylonian Talmud there is evidence of the effect of Parthian customs. On the other hand, many *halakot* in both Talmuds are academic, showing no reflection of the prevailing laws nor of the life of the Jews of the time.

Some *halakot*, particularly those of an academic nature, are characterized by dialectics and sometimes by quibbling and hair-splitting. Only a few *amoraim* indulged in this sort of discussion, however; the Palestinian *amoraim* protested against it, and the majority of Babylonian *amoraim* also condemned it.

Haggadoth.—A considerable part of the Talmuds consists of *haggadoth* of varying types. Those whose purpose is biblical exegesis are homiletical and explain the Scriptures allegorically. Others are stories, legends and proverbs whose purpose is to convey a moral message. Some are theological, dealing with rewards and punishments in the future world, the messianic age and the resurrection. There are *haggadoth* dealing with mysticism, angelology, demonology, astrology, dreams and their interpretation. Others are political, describing in legendary form the lives of the Romans and the Persians. There are historical legends about the lives of biblical and postbiblical people and accounts of the sufferings endured by the Jews. There are also aphorisms and maxims, humour and gaiety.

The aphorisms often reveal psychological insight and a humanitarian spirit: "He who gives charity in secret is greater than Moses himself." "The house that does not open to the poor shall open to the physician." "Let the honour of your neighbour be to you like your own." "There are three crowns: of the Torah, the priesthood, the kingship; but the crown of the good name is greater than all." "Whoever runs after greatness, greatness runs away from him; he who runs from greatness, greatness follows him." "No man is to be made responsible for words he utters in his grief." "The soldiers fight and the kings are the heroes." "When the thief has no opportunity for stealing, he considers himself an honest man." "One eats, another says grace." "The thief invokes God while he breaks into the house."

Superstition.—Superstition figures prominently in the Talmuds, particularly the Babylonian. Though some *amoraim* opposed preoccupation with magic and demonology, regarding them as idolatrous, others succumbed. The sages who deplored superstition were forced by public pressure to permit the wearing of amulets on the sabbath in order to avert the evil eye and protect the wearer from evil spirits. Dreams and their interpretation occupied the minds of men of the ancient world; references in the Bible to dreams and to those who had the wisdom to interpret them rightly are familiar. In the Talmud lengthy passages are devoted to dream interpretation, some sages believing that dreams are prophetic, others that they are of no significance. Belief in omens and astrology was widespread even among intellectuals, hence

astrological speculations are found in the Talmud. Most *tannaim* and *amoraim*, however, condemned these beliefs as idolatrous. Other *amoraim*, regarded by the people as holy men capable of performing miracles, indulged in speculations in theosophy and mysticism. But mysticism was not integral to normative Judaism, and halakists opposed it.

Science.—The sages of the Talmud were learned in geometry, astronomy and medicine, sciences that were of great importance in halakic decisions: geometry in connection with the rules and matters of agriculture, astronomy in relation to the intercalation of the months and years, medicine in the matter of the laws of ritual purity and impurity.

Other Religions.—The attitude of the sages toward other religions was antagonistic. As monotheists, who maintained that God is universal—the God of the entire human race—they opposed idol worship. They forbade the partaking of bread and wine with pagans, since they used wine in their libations to the idols and bread in their worship, and to the Jews the table was sacred. Their attitude toward non-Jews was analogous to that of the Hellenes toward non-Hellenes, but it was based not on belief in racial superiority but on religion, and the sages welcomed proselytes—one who accepted Judaism was regarded more highly than a native Jew. No laws were directed against gentile Christians, but certain strictures were passed upon Jewish Christians, who were regarded as heretics and apostates and suspected besides of being informers to the Romans. The rabbis, since they considered the Jewish Christians to be the destroyers of Judaism, showed great animosity toward them. When Christianity became a gentile religion their animosity disappeared, since the rabbis regarded Christianity as a different religion, one that brought the idea of the universality of God to the pagans. Passages about Jesus in the Babylonian Talmud show that the Babylonian *amoraim* had no conception of the historical Jesus and of the time when he lived; all they knew about him was compounded from hearsay. It is worthy of note that there is no mention of Christianity and its founders in the Palestinian Talmud. Either the rabbis were indifferent, or they were afraid to speak candidly because at that time Christianity was the dominating religion of Rome, or, perhaps, passages concerning Jesus and Christianity have been deleted.

CRITICISM AND COMMENTARY

Attacks.—The first attack against the Mishnah was made by the Church Fathers, who construed it as a menace to Christianity. The Fathers interpreted biblical passages so as to support the truth of Christianity, while the *tannaim* employed the same passages to support their own tradition. There is no word in the Mishnah about the founders of Christianity, hence the Church Fathers inferred that it denied the truth of Christianity. As a new, young religion, Christianity had to fight for its very existence, and the Mishnah was regarded as a threat. Unable to read the Talmud in the original, church authorities relied occasionally on tendentious translations made by Jewish apostates. In the 6th century the emperor Justin prohibited the reading of the Mishnah.

Throughout the middle ages the Talmud continued to be attacked by Christians. A public disputation was held in Paris in the 13th century, and later there were disputations elsewhere. In the early part of the 16th century the apostate Johan Pfefferkorn wrote a bitter attack against the Talmud, on the basis of which the emperor Maximilian ordered it to be burned; the Christian humanist Johann Reuchlin, however, defended the work against the accusations of the apostate, and the emperor rescinded his decree. The Talmud was, however, in fact frequently burned, and it is for this reason that so few early manuscripts survive. As late as the mid-18th century copies were burned in Poland, though after the middle ages the work was subject more to censorship than to destruction.

During the middle ages the Jewish Karaites, motivated chiefly by resentment against the exilarch and the *geonim*, attacked the Talmud as a compilation of casuistic arguments, myths and superstitions, denying also the divine origin of its laws (*see* KARAISM). During the period of decline in Jewish intellectual life during the late middle ages and Renaissance the Talmud came to occupy an exaggeratedly exalted position, being studied even to the exclusion of the Bible. The enlightenment that came in the 18th century, particularly as exemplified by Moses Mendelssohn, brought a reaction. Liberal Jews in modern days do not regard the Talmud as divinely inspired but as a portion of the sacred tradition and a monumental source of Jewish history. In modern *yeshibot* it is still the major, sometimes the sole subject of study.

Commentaries.—The best commentary on the Babylonian Talmud was written by Rashi (*q.v.*), but there are numerous other commentaries and novellae compiled by rabbis throughout the ages. Among translations may be mentioned Herbert Danby's of the Mishnah and the Soncino translation of the Talmud. However they are not perfect, and a critical edition of the Talmud is yet to be made. Many passages are corrupt, and the work was never well edited. While its language is chiefly Aramaic, it is a mixture of many dialects. It may be compared to a primeval, dense forest in which a person will lose his way without a skilful guide. (S. Z.)

Source Criticism.—The Talmud is not immune to the manifold problems besetting all ancient texts, particularly those that were orally transmitted (*see* TEXTUAL CRITICISM). Indeed textual criticism of the Talmud is as old as the Talmud itself, though not until modern times did it become a separate scholarly concern.

The rabbis of antiquity often emended rabbinic texts, inserting readings (*e.g., Talmud Babli, Berakot* 13b), substituting one reading for another (*e.g., T.B. Yebamot* 41a) or rejecting outright Baraitot (*e.g., T.B. Gittin* 73a) or statements of *amoraim* (*e.g., T.B. Pesahim* 11a) because they considered them to be hopelessly corrupt. Nor did later scholars of the Talmud desist from correcting one text on the basis of another that seemed to them to be more reliable. Sometimes they even emended a text without support from another text. Talmudic text criticism, unlike biblical criticism, which had to contend with a long and revered tradition, was always acceptable even to the religiously conservative scholar; it is more often than not the modern liberal scholar who protests against excessive emendation (even when sanctioned by tradition) on the ground that it is inconsonant with what is known about the natural development of texts in general.

That is not to say that the traditional attitude set no limits to talmudic textual criticism. A distinction was always drawn between a reading substantiated by internal evidence in the Talmud itself and a reading not so substantiated. The former was always taken to be valid, while the latter was acknowledged to have been open to the possibility of scribal error. With the advent of modern scholarship, this distinction was no longer compelling.

Source criticism seeks to differentiate between the original statements as they were enunciated by their authors and the forms they took as a consequence of being orally transmitted; that is, between the sources and their later traditions. It is not to be confused with the kind of analysis—frequently carried out by the rabbis of the Talmud—which merely traces the historical sources of a given passage without judging whether or not the passage faithfully reflects these sources. Source criticism claims that the transmission of the Talmud was not, and perhaps could not have been, verbatim, and that the text became altered in transmission, with the result that many statements in the Talmud have not come down in their original form. Instead, what survives is the form assumed in the last phase of transmissional development. While such a study is pertinent to most ancient texts, it is particularly relevant to the Talmud, which primarily consists of quotations and their interpretations.

Traces of source criticism can be found in geonic literature, but credit for pioneering work belongs to the Galician-born scholar H. M. Pineles (1805–70), who in his *Darka Shel Torah* (1863) for the first time offered a systematic critical approach to the study of talmudic sources. J. N. Epstein (1879–1950), professor of Talmud at the Hebrew university, Jerusalem, made a major contribution to source criticism through his comprehensive *Introduction to the Mishna* (1948) and *Introduction to Tannaitic Literature* (1957).

TAM, JACOB BEN MEÏR (1100–1171), a grandson of Rashi (*q.v.*), was the most famous French glossator (*tosafist*) on the text of the Talmud. In 1147 he was attacked and injured by a disorderly band who had attached themselves to the Crusaders. He escaped to the neighbouring Troyes, where about 1160 was held the first of the Jewish synods, for which the Rhinelands became celebrated. At this meeting it was laid down that disputes between Jew and Jew were not to be carried to a Christian court, but were to be settled by fraternal arbitration. New conditions of life had arisen because of the closer terms on which Jews and Christians lived, and Jacob Tam was foremost in settling the terms which were to govern the relations, from the Jewish side. His practical ordinances (*Takkanoth*), connected with marriage and divorce, trade and proselytism, as well as with synagogue ritual, bear the stamp of enlightened independence within the limits of recognized authoritative tradition and law. Of his legal work the most important was collected in his *Sefer ha-yashar*. He was also a poet and grammarian. (I. A.)

TAMALE, the capital town of the Northern Region of Ghana, is situated 437 mi. N.N.E. from Takoradi, Ghana's chief seaport on the Gulf of Guinea, and 406 mi. north from Accra, the capital of Ghana. Tamale lies 600 ft. above sea level in a plain between the White Volta to the west and the tributaries Taha Kulibong and Pagazaa to the east. Its nearest point to the White Volta is at Dalong, 22 mi. away. The climate is hot and wet. The town covers approximately 4.5 sq.mi. Pop. (1960) 40,443.

The official residence of the chief regional officer is in Tamale, and many government departments have their offices there. In addition to the regional education office, government educational establishments include a teachers' training college and a centre for instructing artisans in various trades. The vernacular literature bureau provides newspapers and literature for mass literacy campaigns in the region; personnel for these campaigns and for work in community development are trained at the rural training centre. There is a social and cultural institute in the town, and a public park and polo ground.

Tamale is an agricultural trading centre where the main occupation is farming and crop cultivation in particular. Yams, maize, guinea corn, millet, rice, peanuts and cow peas are grown, and a small quantity of cotton is produced. There is some cotton milling and the shea nut is processed. Commodities exported, but almost exclusively within Ghana, are rice, guinea corn, peanuts, cow peas and shea butter. The principal imports are cotton prints, farm tools, hardware, salt and kola nuts.

The main road, which runs northward from the coast roughly through the centre of the country, passes through Tamale; other roads enter it from the east and west. There is an air service between Tamale and Accra. (J. S. Km.)

TAMARACK: *see* Larch.

TAMARIND, the name popularly applied to a tropical leguminous tree, *Tamarindus indica*, and its pod fruit. The tree is widely distributed in tropical countries, but it is generally considered to be native to eastern tropical Africa, from Abyssinia southward to the Zambezi river. The name (meaning in Arabic "Indian date") shows that it entered medieval commerce from India, where it is used not only for its pulp but also for its seeds, which are astringent; its leaves, which furnish a yellow or a red dye; and its timber. The tree attains a height of 70 to 80 ft. and bears elegant pinnate foliage and purplish or orange veined flowers arranged in terminal racemes.

The pods are filled with an acid juicy pulp containing sugar and various acids, such as citric and tartaric, in combination with potash. The acid pulp is used as a laxative, the pods being largely exported from the West Indies and Indonesia.

TAMARISK, common name for the genus *Tamarix*, a small group of shrubs or low trees constituting the tamarisk family (Tamaricaceae). The species of tamarisk and of an allied genus *Myricaria* (false tamarisk) grow in salt deserts, by the seashore or in other more or less sterile localities in warm-temperate, subtropical and tropical regions of the eastern hemisphere. Their long slender branches bear very numerous small appressed leaves, in which the transpiring surface is reduced to a minimum. The numerous small pinkish flowers, borne in long clusters at the ends of the branches or from the trunk, give the shrubs a feathery appearance. Each has four to five free sepals, and as many petals springing with the four to ten stamens from a fleshy disk. In *Tamarix* the stamens are free, while in *Myricaria* they are united into one parcel. The fruit is capsular and contains numerous seeds, each usually with a long tuft of hairs at one end. The value of these shrubs or trees lies in their ability to withstand the effects of drought and a saline soil; they grow where little else can flourish. On this account the common tamarisk, *T. gallica*, the salt cedar or French tamarisk, is planted on seacoasts and affords shelter where none other could be provided. *T. aphylla*, the Athel tamarisk, native to western Asia, has been introduced as a windbreak in desert areas in southern California. Several species are cultivated as ornamentals.

For tamarisk manna, *see* Manna.

TAMATAVE (known locally as Tòamàsina), chief seaport of the Malagasy Republic (Madagascar), is on the eastern coast. Pop. (1956) 46,272. A coral reef forms a harbour, entered by two openings but exposed to frequent cyclonic storms and to a tidal bore. The town is built on a sandy peninsula.

Imports to Tamatave consist principally of piece goods, farinaceous foods, and iron and steel goods, and exports of gold dust, raffia, hides, caoutchouc and live animals. Of the total foreign trade of Madagascar, 46% is through Tamatave. The town is connected with the interior of the country by a network of roads and railways. Since 1895 the native population has settled in a new village to the northwest.

TAMAULIPAS, a northern Gulf-coast state of Mexico. Area, 30,822 sq.mi. Pop. (1960) 1,024,182. The central and southern parts of the state are mountainous but in the north are fertile plains. The coastal zone, sandy and broken by lagoons, is sparsely inhabited. Inland, the foothills region is wooded and fertile and low alluvial valleys penetrate into the sierras. There are four important rivers in the state. The climate, hot and humid on the coast, is pleasant in the interior. Rainfall is abundant, especially on the mountain slopes of the south. The principal industry is agriculture. Sugar, cereals, tobacco, cotton, fruit and coffee are grown. Stock raising is carried on and istle fibre is prepared for export. Copper is mined and extensive deposits of petroleum and asphalt are being exploited.

Ciudad Victoria (pop. [1960] 50,797), the capital, is a small sierra town about 120 mi. from Tampico. Other towns include Tampico, Nuevo Laredo, Matamoros, Ciudad Madero and Reinosa.

TAMAYO Y BAUS, MANUEL (1829–1898), Spanish dramatist, came of a family connected with the theatre, his mother being the eminent actress Joaquina Baus. The earliest of his printed pieces, *Juana de Arco* (1847), is an arrangement from Schiller, as also is *Angela* (1852), while *Virginia* (1853) is a dramatic essay in Alfieri's manner. *La Locura de Amor* (1855) established Tamayo's reputation as Spain's leading playwright. *Hija y Madre* (1855) is a failure, and *La Bola de Nieve* (1856) is notable solely for its excellent workmanship. Tamayo's straitened means during the next few years forced him to put original work aside and to adapt pieces from Léon Laya, Jules Sandeau and Émile Augier. In this period he produced only one original piece, *Lances de Honor* (1863), which turned upon the immorality of dueling, and led to a warm discussion among the public.

TAMBOV, an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., was formed in 1937. Area, 13,243 sq.mi. Pop. (1959) 1,549,001. It occupies the low, level Oka-Don plain on the watershed between the two river basins. Only in the east does the land rise slightly toward the Volga uplands. Drainage is north to the Oka by the Tsna and its tributaries and south to the Don by the Vorona and several smaller streams. The climate is continental, with a January average temperature of 11° C. (13° F.) and a July average of 20° C. (68° F.). The annual rainfall is 19 in., with a summer maximum. The natural vegetation is forest steppe, much of which has been cleared for agriculture since the soils are rich chernozems. Only along the right bank of the Tsna and along the Vorona are large areas of pine forest on sandy soils.

In 1959 only a small proportion, 408,210 or 26% of the population, was urban. These people live in seven towns and five urban districts, of which the largest are Tambov (172,171) and Michurinsk (80,653). Most of the industry is concentrated in these two towns, the other centres being engaged in processing local farm produce.

Agriculturally the *oblast* is important, with grains occupying first place. Winter rye, spring wheat, maize (corn), oats and millet are grown. Sunflowers are the chief industrial crop, but there is some sugar beet, hemp and tobacco. Potatoes, melons and other vegetables are widespread. Beef and dairy cattle and poultry are the main livestock.

Other principal towns are Morshansk, founded in the 17th century on the Tsna (manufactures of glass, cloth and makhorka tobacco); and Kirsanov (founded 18th century) on the Tambov-Saratov railway (smelting works). (R. A. F.)

TAMBOV, a town and *oblast* administrative centre of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the left bank of the upper Tsna, on the Oka-Don plain, 260 mi. S.E. of Moscow. Pop. (1959) 172,171. It was founded in 1636 as a fortress on the Belgorod defensive line. In 1779 it became centre of a *guberniya* (pre-Revolutionary province). Development came slowly, chiefly in the late 19th century after the construction of the Moscow-Saratov railway through the town. Tambov's chief industry is engineering, chiefly the making of parts for vehicles and farm machinery, and the manufacture of electric motors and turbines, and machinery for the chemical and food industries. The last two are represented by the manufacture of synthetic rubber, dyes and paints and the processing of local agricultural produce. There are also rolling stock repair yards. Apart from the main line, there is a branch railway to Balashov and to Kamyshin on the Volga, and the Tsna is navigable downstream as far as Morshansk for pleasure launches and small barges.

In 1940 the southeastern part and adjacent suburb were constituted as the separate town of Kotovsk. Cultural institutions at Tambov include a pedagogic institute and a school of music. (R. A. F.)

TAMERLANE: *see* TIMUR.

TAMIL, peoples from south India who have perhaps the oldest cultivated Dravidian language and literature. Numbering about 28,000,000 in the 1960s, Tamil speakers (*see* DRAVIDIAN LANGUAGES) inhabited chiefly Madras state and parts of Kerala, Mysore, Andhra Pradesh and northern Ceylon (*q.v.*). Emigrant Tamil may be found in Madagascar, Malaya, Burma, Indochina, Thailand, south and east Africa, the Fiji and Mauritius islands, and the West Indies. The term Tamil was in very ancient times applied to the language and peoples of a wider area of south India, including those now speaking Malayalam. The term is used also to designate the culture and literature of the people; it is a linguistic and geographical word and includes persons of varied social status and customs.

The Tamil area in India is a centre of traditional Hinduism. The largest occupational group are cultivators, and although most are Hindu, there are Christian and Muslim Tamil. They are predominantly patrilineal with patrilocal residence; in the kinship system of the lower castes, however, matrilateral and affinal bonds are also found. Traditional marriage alliances are maintained between clanlike exogamous patrilineal subdivisions of endogamous castes and tribes. Among non-Brahmans divorce is common, as is remarriage and widow remarriage; Brahmans and some non-Brahmans disapprove of these and place greater emphasis on the lineage and on respect for elders in the extended family.

The Tamil have a long history of achievement; sea travel, city life and commerce seem to have developed early. Tamil trade with Greeks and Romans is verified by literary, linguistic and archaeological evidence. Their rich literature reaches to the early Christian era, and Tamil schools of personal religious devotion (bhakti) have been important in Hinduism (*q.v.*). South Indian classical music and the celebrated classical dance Bharata Natyam (*q.v.*) owe much to the Tamil who are masters and teachers of these arts.

(M. B. S.; R. RA.)

TAMIL LANGUAGE, one of the principal Dravidian languages (*q.v.*) spoken in South India and perhaps the only example of an ancient classical tongue which has survived as a spoken language for more than 2,500 years with its basic structure almost unchanged. The official language of Madras (*q.v.*), it is one of the 14 major languages recognized by the constitution of India (1949). At the 1951 census, Tamil was the mother tongue of 26,546,764 persons, 7.4% of the total population of India. Moreover, it is also spoken in the north of Ceylon and by many settlers in South and East Africa, Mauritius, Malaya and Fiji.

The Tamil script can be traced to Grantha and Vaṭṭēluttu epigraphical sources of the 3rd century A.D. onward (*see* TAMIL LITERATURE). That it had reached something akin to its present form by the 11th century may be seen from the inscription of Rājarāja Cola in the Great Temple in Thanjavur. Tamil script differs from others of South India mainly in excluding separate characters for the voiced velar, palatal, retroflex, dental and labial plosives, the voiced and voiceless aspirated plosives of these series, and the sibilants. However, the character of the palatal plosive *c* is realized as a dental or palatal sibilant in certain positions and is used to represent sibilants in loanwords. Also, Grantha characters are borrowed to represent the sibilants *ṣ, sh,* the voiced plosive *j* and the voiced spirant *h*. Other plosives are represented by the corresponding voiceless unaspirated plosive.

Thus, the character for *k* represents also *kh, g* and *gh* in, for instance, Sankskrit loanwords. Moreover, the plosives are realized as voiced in certain positions according to fairly consistent rules, the principal being that a medial single plosive is realized as voiced, and a medial doubled plosive as voiceless with tense utterance. Tamil includes three consonants not found in the syllabaries of the Indo-Iranian languages of India and not now fully represented in other Dravidian languages: the trilled *r,* the alveolar nasal *n* and the retroflex fricative *l*.

Like other Dravidian languages, Tamil is regarded as agglutinative in formation. While its close affinity with other south Dravidian languages, especially Malayāḷam and Kanarese, is undisputed, the affiliations of the whole family have not been satisfactorily explained. The classical view, as stated by R. A. Caldwell, is that they are connected with the Scythian languages, but many of the similarities of structure and forms he cites may be accidental.

Tamil exhibits inflexional features also, wherein postpositional words are reduced to suffixes, sometimes monosyllabic. It agrees generally with other languages in broadly classifying words into verb roots, nouns and adjectives. In common with other languages of the same family, there is evidence, although vestigial, of a separate negative verbal conjugation and, in the sense of the Spanish *ser,* the verb for "to be" is unexpressed except in the negative. Case terminations are added to the plural noun-suffix and are unaffected by it, being identical with those used for the singular.

TAMIL LITERATURE. Tamil is perhaps the best-known of the Dravidian languages (*q.v.*) spoken in South India. Apart from Sanskrit, its literature is the oldest in India and, if epigraph-

ical sources are included, may be said to commence in the 3rd century B.C. with some fragmentary cave graffiti found near Madurai. (*See* also TAMIL; TAMIL LANGUAGE.)

Period of the "Sangam".—The earliest Tamil writings that may properly be termed literature are those of the *sangam,* or "literary academy." Tradition, much of it doubtless fanciful, tells of a *sangam* at Madurai which grew up during the middle ages, where a number of anthologies of secular court poetry were compiled—the Eight Anthologies, *Eṭṭuttōkai,* and the Ten Songs, *Pattuppāṭṭu.* Possibly unique in early Indian literature, which is almost entirely religious, these poems are concerned with two main topics, love and the praise of kings and their deeds. Many, especially on the latter subject, display great freshness and vigour and are singularly free from the literary conceits of much of the other early and medieval literatures of India (*see* INDIAN LITERATURE).

Since they are secular, these poems are also free from the complex mythical allusions which are such an outstanding feature of most Indian art forms. *Sangam* poetry seems to be at least partly based on personal experience; in this respect it is curiously modern and unlike anything else to be found in India before the late 19th century. From references to trade with the west and other internal evidence, it seems likely that these poems belong to the first four centuries A.D., when trade with Rome via the middle east was still active.

Paripāṭal, possibly the last of these anthologies, marks the transition to the next, more formal, stereotyped style, for it includes both religious poetry, abounding in the usual allusions, and, still in the older vein, some fine descriptive poetry, which depicts the course of the Vaigai river, on which Madurai stands.

Sixth to Ninth Centuries.—To the 6th century and after belongs that great collection of Śaiva religious poetry (*see* HINDUISM: *Gods*) called, collectively, *Tirumuṟai.* Among its 12 books are the *Tevāram,* consisting of the hymns of Appar (Tirunāvukkaracu), Tiruñāṉacampantar and Cuntarar; and Māṇikkavācakar's mystical poem *Tiruvācakam* (Eng. trans. by G. U. Pope). The 12th book, the 12th-century *Pēriyapurāṇam* of Cekkiḻār, describes the lives of the 63 Śaiva *nāyaṉmār* ("saints").

Of possibly the same period as the first few books of *Tirumuṟai* are the "Eighteen Minor Works." Largely didactic, these include the well-known collections of aphorisms, *Tirukkuṟaḷ,* by Tiruvaḷḷuvar. This work is highly esteemed by the Tamilians, and there are several translations. Another similar work is the *Nālaṭiyār.*

Similar in subject matter to the *Tevāram,* though somewhat later in date, are the hymns of the *Nālāyirappiraṉantam,* which differ only in that they praise the god Viṣṇu (Vishnu). They are the work of the 12 Vaiṣṇava devotees or Āḻvārs, the most interesting of whom is, perhaps, Āṇṭāḷ, the girl-foundling reared by a Vaiṣṇava priest.

The epics *Cilappatikāram* and *Maṇimēkalai,* written by Iḷaṅkovaṭikaḷ and Cāttaṉār respectively, may probably be assigned to the 6th or 7th century. The former tells of a merchant Kovalaṉ who neglects his wife Kaṇṇaki, lavishing his wealth on a courtesan called Mātavi. Later, impoverished as a result of his excesses, Kovalaṉ and his faithful wife travel to Madurai, where they try to start a new life, selling Kaṇṇaki's golden anklets to raise capital. Wrongfully accused of stealing these from the queen, Kovalaṉ is executed. Kaṇṇaki fully exonerates her husband before the king, who dies of remorse, and she herself, in her frenzied grief, tears off her left breast and curses the city, which is consumed by fire. She then makes her way to another royal city, Vañci, where she dies, and is received into heaven to join Kovalaṉ.

Though a Buddhist work, *Maṇimēkalai* is a sequel to the *Cilappatikāram* in that its heroine, Maṇimēkalai, is the daughter of Mātavi by Kovalaṉ. Mother and daughter have both become Buddhist nuns; the prince, Utayakumāraṉ, falls in love with Maṇimēkalai, and the pair finally realize that they were married in a former birth.

Ninth to Twelfth Centuries.—Three famous Tamil poets, Kampaṉ, Oṭṭakkūttaṉ and Pukaḻenti, belong to this period, but it is not possible to date them with any exactness. Kampaṉ was author of the principal Tamil version of the *Rāmāyaṇa.* In his version, given a South Indian setting, Rāma is regarded not only as hero of the story but as a god and incarnation of Viṣṇu—as is usually the case with vernacular *Rāmāyaṇas* in India. The work, begun by Kampaṉ, was completed by Oṭṭakkūttan.

Cayaṅkoṇṭāṉ's *Kaliṅkattupparaṇi,* an 11th-century work, describes the victorious war waged by the Coḻa king against the neighbouring ruler of Kaliṅga. It opens with a grandiose genealogy of the Tamil king, and closes with a gruesome description of the carnage of battle and of the corpses being devoured by shedevils.

A number of commentators and grammarians belong to this period. Among the former may be mentioned Aṭiyārkkunallār, who wrote the commentary on *Cilappatikāram,* and Naccinārkkiṉiyar, who, in addition to commentaries on *Pattuppaṭṭu* and some of the *Eṭṭuttōkai,* wrote one on part of the early "grammar" *Tōlkāppiyam.*

Twelfth to Sixteenth Centuries.—Tamil literature became increasingly concerned with philosophical treatises and with creating *Purāṇas* (anthologies of religious legends), which, in this case, describe the myths about the various shrines of South India. Most important among the former are perhaps those (for example Mēykaṇṭatevar's *Civañāṇapōtam*) which expound Śaiva-siddhānta philosophy.

Among the *Purāṇas* mention may be made of the *Tiruviḷaiyāṭaṟpurāṇam* of Parañcotimuṉivar, which recounts the 64 divine sports of the god Śiva (Shiva) in connection with the founding of the great temple at Madurai.

European Influence and the Modern Period.—After the collapse of the Vijayanagar empire in 1565, South India was split into a number of petty states, but some of these, such as Thanjavur (Tanjore), continued to patronize writers. Missionaries from the west were also active in the Tamil area. The earliest of these, apart possibly from St. Francis Xavier (*q.v.*), were Roberto de Nobili in the 17th century and another Italian Jesuit, Joseph Beschi, born near Mantua in 1680. Both lived as Hindu ascetics, and Beschi studied not only grammar but composition. He produced an epic, the *Tempāvaṇi,* which tells the story of St. Joseph and is based on an earlier model, *Cīvakacintāmaṇi.* In 1738 he produced a grammar of Tamil in Latin, probably the first to be written in a European language.

British Tamil studies were initiated by the manuscript collections of Col. Colin Mackenzie, who arrived in India in 1783. Later scholars of Tamil from the west included Robert Caldwell, whose *Comparative Grammar of the Dravidian . . . Languages* appeared in 1856; and the Rev. G. U. Pope who, besides writing a number of grammars, translated several Tamil works, including the *Tirukkuṟaḷ.*

In the 19th century, Tamil increasingly availed itself of western literary forms and ideas, and prose, hitherto reserved for inscriptions and commentaries, became accepted as a literary medium. The first novel was *Piratāpa Mutaliyār Carittiram,* by Vedanāyakam Piḷḷai. The most famous poet of modern times is C. Subrahmanya Bharati (d. 1922). Perhaps his most lasting work is *Kaṇṇan Pāṭṭu,* a touching and lyrical cycle on the god Kṛṣṇa (*see* VISHNUISM). His work combines the best of the techniques of east and west. More recent is *Pāratidācan* whose poems about children and the family are especially attractive.

Much modern Tamil writing is devoted to regional politics and as such can hardly be said to be of permanent value; however, such writers as Aṇṇāṯturai and Karuṇāniti have proved their worth in other work; for example, in the writing of filmscripts, and their contribution to Tamil literature may become more lasting. The economic lot of South Indian writers in the mid-20th century was a hard one, and a number of excellent literary journals, such as the humorous weekly *Āṉanta Vikaṭaṉ* and the magazine *Kalki* afforded them a most necessary medium and helped to foster good writing.

TAMM, IGOR EVGENYEVICH (1895–), Russian physicist, who was awarded the 1958 Nobel prize for physics jointly with P. A. Cerenkov and I. M. Frank "for the discovery and interpretation of the Cerenkov effect," was born in 1895. This effect, which was first described by Cerenkov in 1934, is concerned with the emission of light waves by electrons moving at very high speeds and is of great importance for the study of nuclear physics.

Tamm, a professor at Moscow university, and his co-worker I. M. Frank provided a theoretical explanation of the Cerenkov effect in 1937. He became one of the best-known Russian physicists and a member of the Academy of Sciences of the U.S.S.R.

In 1946 Tamm shared the Stalin prize with Cerenkov and Frank for their joint work on electron radiation. He worked on the quantum theory of diffused light in solid bodies, on the photo-effect on metals and on methods for the control of thermonuclear reactions. His method of interpreting the interaction of elementary nuclear particles is known as the Tamm method. He is the author of treatises "On the Magnetic Moment of the Neutron" (1934) and "Relativistic Interaction of Elementary Particles" (1935). (W. J. Bp.)

TAMMANN, GUSTAV HEINRICH JOHANN APOLLON (1861–1938), German physical chemist whose researches into the states and reactions of matter, especially of metals, made him one of the founders of metallurgy, was born at Yamburg (Kingisepp), near St. Petersburg (Leningrad), on May 28, 1861. He studied at the University of Dorpat (Tartu) in Estonia, and in 1892 became professor and director of the Chemical institute there. In 1903 he went to the University of Göttingen in Germany as a professor of inorganic chemistry and was head of the Institute of Physical Chemistry there from 1907 to 1930. He died at Göttingen on Dec. 17, 1938. Tammann made fundamental investigations of the changes in the condition of matter and their dependence on temperature and pressure and also studied the reactions of matter in a hard and brittle condition. Especially valuable were his introduction of thermal analysis in the construction of constitutional diagrams of metals, and his researches into the nature and structure of alloys.

Among Tammann's publications were *Lehrbuch der Metallographie* (1914; 4th ed., 1932); *Die chemischen und galvanischen Eigenschaften von Mischkristallreihen und ihre Atomverteilung* (1919). He was an editor of *Zeitschrift für anorganische und allgemeine Chemie.* (O. W. K.)

TAMMANY HALL. The name popularly used in connection with the executive committee of the Democratic party of New York county; sometimes applied to the entire party structure in the county or in the city. From about 1800, with only occasional intermissions, as a political organization it played an important role in the city and exercised considerable influence in state administration and national affairs.

Origin.—Before the American Revolution groups proclaiming fealty to King George III were organized in societies bearing the names of St. George, St. Andrew and St. David. As a countermove, the revolutionists formed associations called the Sons of Liberty or the Sons of St. Tammany, the latter after Tammanend, a Delaware Indian chief, famed for wisdom, benevolence and love of freedom, with the "saint" thrown in as a form of ridicule. After the achievement of American independence, in 1776, these associations dissolved.

During the 1780s the leaders of the aristocratic and propertied elements of New York city and state successfully managed to limit the suffrage to freeholders and to strengthen the Order of the Cincinnati, a group of former officers of the Revolutionary army with centralist and monarchial tendencies. To resist these influences, William Mooney, an upholsterer in New York city, founded the Society of St. Tammany or Columbian Order, on May 12, 1789, a fortnight after the establishment of the national government. His purpose was the creation of a national society native in character and democratic in principle and action. Its officers were given Indian titles; the society's chief was grand sachem and his fellow chiefs, sachems.

For more than three decades after its organization, Tammany represented the middle class opposition to the pretentions and power of the aristocratic party. Its "democracy" did not incorporate the aspirations of the lower economic groups. In that period it also lost its national and nonpolitical character and became intimately identified with politics in New York city.

Under the control of Aaron Burr until his political downfall after killing Alexander Hamilton in a duel in 1804, the society had an influential share in bringing about victories of the Republican (later called the Democratic) party and was richly rewarded, particularly by Thomas Jefferson after his election as president in 1800.

Organization.—Criticisms made by the opposition that a private society was engaging in politics resulted in a separation of the hall's social and political functions. In 1805 the Society of St. Tammany obtained from the legislature a charter of incorporation as a benevolent and charitable body to give relief to members and others. Politically, the Democratic party was organized as an apparently distinct body; in reality, however, the society's sachems controlled the political mechanism and by preventing hostile factions from meeting in the society building, Tammany hall, claimed the right of party regularity.

The political organization initiated at that time consisted of general, nominating, corresponding and ward committees. In the general committee was vested the power of convening the party's meetings and of making all necessary arrangements for elections. Composed originally of 30 members, three from each of the city's ten wards, this committee was gradually expanded until it had many thousands of members penetrating every section of the city. The real power consequently passed into the hands of the ward leaders, later organized as the executive committee of the party.

Boss Rule.—As early as 1806–07, revelations of widespread corruption of Tammany city officials resulted in the removal of the controller, the superintendent of the almshouse, the inspector of bread and others. Despite such proved charges, many of the removed officials, including the society's founder, remained powerful Tammany sachems.

The bitterest opponents of Tammany were the Irish immigrants who were ineligible to be members of the "native-born patriots." As a protest against Tammany bigotry, hundreds of Irish migrants broke into a general committee meeting on the evening of April 24, 1817. Within a few years, the propertied leaders of Tammany were forced for their own preservation to take in the immigrants, naturalize and vote them, and join in the fight for manhood suffrage.

In the 1830s the pressures exerted by the Workingmen's party and its successor, the Equal Rights party, forced the general committee to oust the banking and merchant leaders. The election of its grand sachem, Martin Van Buren, as president of the U.S. in 1836 redounded to Tammany's prestige. Within a few years, however, the immigrant groups, organized into gangs, came under the control of the astute, unscrupulous and engaging Fernando Wood, several times mayor of New York, who used them to break with and later control Tammany. Grand Sachem William M. Tweed initiated complete boss domination of the hall in 1868. Corruption reached a climax under Tweed, when New York city was plundered of more than $200,000,000. Tweed died in jail but most of his confederates retained their wealth. Throughout the world, Tammany became synonymous with corruption.

John Kelly, who succeeded Tweed, induced the leading reformers like Samuel J. Tilden, August Belmont and Horatio Seymour to serve as sachems. The real resuscitating factor, however, was the attachment of the tenement house masses to the district leaders. The helping hand outweighed all of the denunciations. Richard Croker in 1886 and his successor in 1902, Charles F. Murphy, carried on the façade of making liberal avowals and supporting progressive candidates for the top of the ticket but failed to curb corruption within the administrative machinery.

Reform.—After Murphy's death in 1924, Judge George W. Olvany became county leader and with the assistance of Gov. Alfred

E. Smith sought to alter the character of the hall. On March 16, 1929, Judge Olvany resigned and was succeeded by a leader of the old school, John F. Curry. Revelations of corruption in Mayor James Walker's administration, as shown in the Seabury report, discredited Curry but he remained in power until successive defeats of Tammany candidates led to his replacement by James J. Dooling in July 1934.

During the 12 years of Fiorello LaGuardia's reform administration, Tammany declined in power and was eclipsed by the more powerful Brooklyn and Bronx Democratic leaders. Many Democratic party candidates repudiated Tammany. The organization found itself in dire financial condition and had to give up its headquarters in the building maintained by the Tammany society. A succession of county leaders—Timothy J. Sullivan, Michael J. Kennedy and Edward Loughlin—promised the elimination of corruption and pledged leadership for good government but failed to induce public confidence in the hall. In the election of 1945, however, Tammany once more established its ability to turn out a sizable vote. The newly elected mayor, William O'Dwyer of Brooklyn, sought to control Tammany by ousting Loughlin and forcing the acceptance in March 1947 of Frank J. Sampson as county Democratic leader.

Lacking the support of the district leaders, Sampson functioned as a figurehead and was soon replaced by Hugo Rogers, Manhattan's borough president. An embittered struggle between city hall and Tammany ensued, reflected in a series of district leadership fights in the 1949 primaries in which the regular organization defeated a group of insurgent reformers. Rogers, however, was ousted in favour of Carmine G. De Sapio.

Pressures from within and outside the organization brought about a reconciliation of Mayor O'Dwyer and the new Tammany leader but charges of underworld control of some district leaders and of others high in Tammany councils led to insistent demands for reform. Acting Mayor Vincent R. Impellitteri, who had been denied the regular nomination, ran as an independent, anti-Tammany candidate in the special election in 1950 and beat the organization decisively.

The hall lost other important local and city elections to independent Democrats, moreover. De Sapio managed, however, to stave off threats to his leadership in the primary campaigns of 1951 and 1953. In 1953, he joined with Edward Flynn of the Bronx to support Manhattan Borough Pres. Robert F. Wagner, Jr., for the Democratic mayoralty nomination. After Flynn's death and Wagner's nomination and election, De Sapio was recognized as an important leader. He succeeded Flynn as Democratic national committeeman and also became secretary of state for New York.

TAMMERFORS: *see* TAMPERE.

TAMMUZ, Sumerian, Babylonian and Assyrian god, who died and rose annually with dying and reviving vegetation, originally *Dumu-zi*, "the son who rises, goes forth (from the nether world)," but generally interpreted "faithful son." Philologically both interpretations are correct, and no Accadian commentary exists to explain which meaning was accepted by them. The interpretation as "the son who rises," "the resurrected child," accepted in this article, is new and differs from all views held in the standard works on this cult. It is clear, however, that the main principle of this cult is the resurrection of the dying god, and the verb *zi* stands for the root *zig* to rise up, not *zid*, to be faithful. (*See* S. Langdon, *Sumerian Liturgies and Psalms*, p. 287, 17, *ušubba-za uziga-za*, "In thy fall and in thy resurrection.")

There are many titles of the youthful god, loved by his sister, the earth and heaven goddess, Innini (Ishtar), who descends yearly into Aralû (under-world) at the time of his death to bring him back to earth in her bosom. Since he represents the mystery of life and death, as seen in the withering vegetation of the hot Mesopotamian summer, and the rapid renewal of its life at the season of the spring rains, Tammuz is the patron of flocks and irrigation as well as of vegetation. Titles such as god *Sipa*, the shepherd, *umun mirsi*, lord of the flood, god *Ab-ú*, father of vegetation, god *Zulumma*, god of the date palm, are not so old as those which reveal theological speculation concerning the brother, lover and husband of the earth mother. Theology gave rise to this, the most widely spread and profoundly religious aspect of West Asiatic and Egyptian religion (where it appears as the cult of Osiris and Isis). *Dumu-zi* appears in the oldest texts without a divine title, *c.* 3200 B.C., and in Sumerian texts of Eannatum of Lagash (*c.* 2850 B.C.), as god *Dumuzi-apsu*, "risen child of the deep," describing him as the son of the god of the nether sea of fresh waters, *Ea*, *Enki*, a title confined apparently to early Lagash, where he appears more often under the title Ningišzida, "Lord of the faithful tree," a title which developed into an independent deity. In the legend of Eridu, in which Adapa is sent to the gates of heaven for judgment because he had broken the wings of the south-wind, he found Tammuz and Ningišzida at the gate of heaven; they offered him bread and water of life, which he, on the advice of the water god of Eridu, refused and thus lost immortality. Tammuz and Ningišzida appear to have been identified with the stars Castor and Pollux or, perhaps, Procyon and Sirius.

The liturgical wailings for Tammuz during the period of his sojourn in Aralû are numerous and describe every aspect of the theological doctrines concerning him. They are invariably composed in Sumerian, rarely with Accadian interlinear translation. These wailings occurred at midsummer, and the sixth month of the calendar at Lagash from the 28th to the 24th centuries is named the "month of the festival of Tammuz." There is a variant name for this month at Nippur, called "month of the mission of Innini," referring to her descent to Aralû in search of her departed lover.

The Babylonians retained the old name of the fourth month and for some reason described it as the "month Tammuz," corresponding to July, retaining the name "month of the mission of Innini" for the sixth month (Elul). In this month (fourth) Tammuz is said to have been bound, and the liturgies speak of his having been drowned among flowers which were thrown upon him as he sank beneath the waves of the Euphrates. He is described as the shepherd who left his flocks, as the shepherds sat in the fields wailing for Tammuz.

There is a strange inconsistency in the hymns of these wailings concerning the relation of the mother goddess to her lover, Tammuz. In the early Sumerian texts she is his sister, but soon the Semitic view that she is his mother prevails. The two theories appear inconsistently together throughout the entire history of the cult. He is, however, invariably the husband and lover of the otherwise consistently described virgin goddess of love, Innini, Gestinanna, *Bêlit-sêri*, and the cult is particularly associated with the great city Erech, home of the cult of Anu, the heaven god, and Innini. In all ceremonies connected with his cult his mother or sister is invariably associated with him, and it is the one aspect of Sumerian and Babylonian religion which may be described as universal. Badtibira, near Erech, seems to have been the original seat of the cult, and in the Sumerian tradition of the ten prediluvian kings, the name of one at Badtibira is Dumuzisipa, "Tammuz the shepherd"; one of the names of Tammuz is Tibira. No great temple was built to him, and a few casual references to a temple of Tammuz clearly refer to shrines in the temple of the local deity reserved for the wailings and mystic ceremonies of the cult. Worship of Tammuz spread far beyond the lands to which the Sumerian religion was principally confined. Ezekiel speaks of it as firmly installed at Jerusalem in his time; it is mentioned in the Christian era in Mandean and Syriac literature, and it survived among the Sabeans at Harran as late as the middle ages.

In astrology Tammuz was identified with Aries; in the magic rituals he is symbolized by a white kid, and he is also connected with the ram, which led to this astral identification. Under the title *Sibzianna*, "faithful shepherd of heaven," he was identified with Orion. During the period of deified king worship in the Dungi period of Ur, and in the time of the Isin dynasty, the deified kings habitually identified themselves with Tammuz and were worshipped as husbands of the mother goddess. For this

reason it has been argued that the cult arose in prehistoric times when a king was put to death as a sacrifice to the earth mother in order to secure the good will of the deity of vegetation. There is, however, no evidence for this in the earlier texts, and so far as Sumerian religion is concerned, the theory must be dismissed as unproved. He was held to be a god of healing, bestower of health and one who, like all other deities, had power over the demons.

It is obvious that a cult which is based upon the death and resurrection of a propitiating god and upon the love of a divine mother who wails for her son, has direct connection with the facts and the theological views based upon them, which gave birth to Christianity. But the form of the cult which apparently most directly affected the origins of Christianity is that in which Marduk of Babylon was identified with Tammuz. At the Nisan or new year festival at Babylon, Bêl (Marduk) was said to have been imprisoned in the lower world, and a priestess weeps at his sepulchre. A malefactor was slain with Bêl and they descend together to the land of darkness. Beltis, his wife, descends to hell to seek him, and Bêl's garments are given to Ishtar (mother of Tammuz). Bêl was laid in a sepulchre, from which he soon comes forth. This Marduk transformation of the national Tammuz cult is only another effort of the priesthood of the capital to enlarge the worship and importance of the local cult. It obtained nowhere else in Babylonia and Assyria, and may be regarded as a true interpretation of what transpired regularly in the Tammuz cult itself. That the cult had direct influence upon the origins of Christianity cannot be denied, and the Greek cult of Adonis owes its essential content to the Sumerian Tammuz.

(S. L.)

TAMPA, the seat of Hillsborough county, Fla., U.S., the principal manufacturing city and agricultural centre on the west coast of the state, is located at the mouth of the Hillsborough river as it enters an arm of Tampa bay. The population in 1960 was 274,970, an increase of 120.5% in the decade; that of the Tampa-St. Petersburg standard metropolitan statistical area (Hillsborough and Pinellas counties) was 772,453, an increase of 88.8%. (For comparative population figures for the two cities *see* table in FLORIDA: *Population.*) (*See* also SAINT PETERSBURG.)

History.—Tampa was the name of an Indian settlement recorded by historians in the 16th century after Spanish explorers, including Hernando de Soto, and missionaries landed in its vicinity. Fort Brooke was established on the site in 1824 when the U.S. army began the removal of Seminole Indians from north to south Florida. The fort was also active in the seven years of warfare (1835–42) brought on by attempts to remove the Indians to the west, and during the American Civil War it was bombarded and the port blockaded to prevent the shipment of cattle from Tampa to Cuba. Tampa was incorporated in 1855. In 1886 Vincente Martinez Ybor induced several cigar manufacturers to move there after they had been driven out of Havana, Cuba, by revolutionary disorders and from Key West because of labour disturbances and a disastrous fire. Tampa became a world leader in the production of clear Havana handmade cigars.

The greatest developer of Tampa was Henry B. Plant, who made it an international port and tourist resort. In the mid-1880s he connected the city by a standard-gauge railway with lines to the north; he also inaugurated steamship service to Key West and Havana. In 1891 Plant opened the Tampa Bay hotel, a dark red brick castle of Moorish architecture topped by silvery domes and 13 minarets on which he had lavished $3,000,000. Five stories in height and extending over a 6-ac. tract on the Hillsborough river, it became one of the popular luxury hotels of the world.

During the Spanish-American War about 30,000 soldiers were camped in and near the city before embarking for Cuba. Cigar makers supported the Cuban independence movement, their aid being organized by the Cuban patriot José Martí; the cottage in Tampa where he made his headquarters is now a shrine.

The Latin quarter, known as Ybor City, which accounts for about 15% of the population, is the home of Spaniards and Cubans connected primarily with the cigar industry. They maintain their own imposing social clubs and hospitals. Their restaurants have an international reputation.

In the mid-1920s the man-made Davis Islands were created in the bay to provide sites for hotels, residences, apartments, a hospital and an airport. A landscaped 6-mi. boulevard bordering the crescent-shaped bay forms a scenic residential section.

Commerce, Industry and Transportation.—Tampa is a port of entry; after the opening of the Panama canal in 1914 it became one of the most important ports on the Gulf of Mexico. The location of two-thirds of the state's citrus groves in the Tampa area has made the city a centre for processing fruit. A large percentage of all phosphate mined in the U.S. is extracted from the adjoining county; much of it is shipped from Tampa. In addition to the numerous cigar factories there are more than 700 manufacturing plants. The tourist business is also important in the economy. The city is well served by rail and air lines as well as by harbour facilities.

Education and Recreation.—The University of Tampa, a private institution chartered in 1931, in 1933 was given a 99-year lease on the Tampa Bay hotel building by the city. Florida Christian college is a private junior college chartered in 1944. The state-supported University of South Florida was established in 1958 and opened in 1960. Features of the winter season in Tampa are the Gasparilla and Latin-American pageants and festivals, baseball, golf, tennis and sailing. (A. J. H.)

TAMPERE, formerly Tammerfors, an industrial city of Finland in 61° 28′ N., 23° 45′ E., on the rapids connecting Lakes Näsi-järvi and Pyhä-järvi, and at a railway junction. Pop. (1960) 126,573. It manufactures textiles, paper and leather goods.

TAMPICO, a city and leading port of Mexico, in the state of Tamaulipas, on the north bank of the Pánuco river, about 6 mi. from the Gulf of Mexico. In summer the climate is hot and humid, although a sea breeze modifies the temperature somewhat. In winter the temperature falls to freezing on occasional days when northers blow down along the Gulf coast. Tampico is almost surrounded by swampy lands and lagoons.

The eastern and poorer part of the town stands on low ground only two or three feet above the river, and is subject to inundations. However, a modern sewer system, up-to-date street paving and a better water supply, constructed after the beginning of the 20th century, greatly improved the sanitary condition and reduced the death rate from epidemics. The western part rises about 150 ft., consists largely of residential districts and is provided with still better sanitary equipment. The business section is well built, largely of stone and brick, while many of the newer structures are of reinforced concrete and rise to six and seven stories. The city is well supplied with gas and electric light.

Tampico has excellent railway facilities, road connections with the Pan-American highway, and air services are available to Mexico City, Veracruz, Brownsville, Tex., and other points. Although a bar exists at the mouth of the Pánuco river, jetties were built and the depth increased by dredging, so that vessels drawing up to 33 ft. can approach the water front of the city, while scows and other boats of light draught can navigate the river for more than 100 mi. upstream.

The Chijol canal, begun in 1901, affords a waterway 6 ft. deep and 25 ft. wide for about 75 mi. southward through the oil fields to Túxpan. Modern port works, spacious enough to accommodate at the wharves 14 vessels at a time, steel sheds and warehouses, a union railway station within easy reach of the water front and excellent equipment for loading oil tankers make Tampico the most up-to-date harbour in Mexico.

Tampico owes its importance to four of the most productive oil fields in the country (the Ebano, Pánuco, Huasteca and Túxpan) which are situated within about 100 mi. of its site. Until 1901 it was a second-rate port, outlet of the fertile but relatively

underdeveloped hinterland, with a reputation for unhealthful and unsanitary conditions. The rapid exploitation of petroleum resources resulted in a marked increase of population from about 10,000 in 1900 to 24,980 in 1921, to 82,475 in 1940, to 94,342 in 1950 and to 134,204 in 1958. For several years Tampico ranked as the greatest oil port in the world. Pipelines lead from the nearby fields, while fleets of scows bring oil from farther up the river. Pipelines and barges together are capable of transporting approximately 1,200,000 bbl. of oil daily from the fields to the port of Tampico.

Up river from the port agricultural activities were stimulated, fruits, vegetables and grains being grown to supply the local food demands. Modern commercial establishments are stocked with U.S. and European goods. Hotels, clubs, restaurants and places of amusement are numerous and well served. Because of high prevailing wage rates, the standard of living is generally higher than in most Mexican cities. Tampico is also noted as a vacation resort with excellent bathing, golfing, hunting and fishing.

Besides those connected directly with the oil business, the industrial establishments of Tampico include many for the handling and repair of oil well machinery, yards for the building of river boats, an electric light and power plant, factories for making ice, clothing and fruit preserves, sawmills, etc. In addition to petroleum, the exports include silver bullion (from San Luis Potosí, Aguascalientes, Torreón and Monterrey), istle fibre, sugar, hides, live cattle, cottonseed cake, honey, fustic, sarsaparilla, coffee and copper ores.

Tampico grew around a monastery which was founded in the ruins of an Aztec village by Andrés de Olmos, a Franciscan friar, in 1532. It was destroyed in 1683 by pirates and not reoccupied until 1823 when Gen. Lopéz de Santa Anna ordered that the site should be settled.

In 1829 a Spanish force under Isidro de Barredas was defeated at Tampico by Santa Anna. It was briefly occupied by U.S. forces during the Mexican War and again in 1862 by the French. The arrest of some American sailors in Tampico on April 9, 1914, led to the bombardment and occupation of Veracruz on April 22, 1914, by the U.S. navy. (J. W. Mw.; R. B. McCk.)

TAMWORTH, city of New South Wales, Austr., on the Peel river, 280 mi. by rail N. of Sydney. Pop. (1961) 19,064. Tamworth is the main provincial city of north and northwestern N.S.W. and the market of a pastoral and agricultural district. Flour and saw milling, the production of glucose, starch and kindred wheat products, egg processing, joinery and the manufacture of furniture are its main industries. Tamworth was the first city in Australia to provide electric street lighting, in 1888.

TAMWORTH, a market town and municipal borough in the Lichfield and Tamworth parliamentary division of Staffordshire, Eng., 15 mi. N.E. of Birmingham by road. Pop. (1961) 13,555. Area 4.2 sq.mi. It lies at the junction of the Tame and Anker rivers, in open country with wooded uplands. Offa, overlord of Mercia, built a palace there in the 8th century and surrounded the burgh by the great entrenchment known as Offa's dyke. During the 9th century Tamworth was destroyed by the Danes, but in A.D. 913 Aethelflaed, daughter of Alfred the Great, defeated them and built a timbered stockade at the junction of the rivers where the present castle stands. William the Conqueror bestowed the manor upon Robert de Marmion, who built the Norman castle, the walls and keep of which remain. It was largely restored in the Jacobean period. Tamworth, a borough since Saxon times, once possessed a royal mint, dating from Aethelstan's reign. Originally half the borough was in Staffordshire, the other half in Warwickshire, but in 1319 Edward III granted the Warwickshire half to the burgesses by letters patent. The town was incorporated by Elizabeth I in 1560 and a further charter was granted by Charles II in 1663. The whole borough was transferred to Staffordshire in 1889. The church of St. Editha (8th century) was rebuilt, after the Danes had burned it, by king Edgar who made it collegiate in A.D. 963. The existing Decorated building was erected after a fire in 1345. The grammar school, granted a charter by Elizabeth I in 1588, once formed part of the collegiate church. Guy's almshouses (1678) were endowed by Thomas Guy, founder of Guy's hospital, London, who also built the town hall over the open market in 1701. An ancient fair in honour of St. Swithin is still held (July 26). Two members of parliament were returned by the borough from 1562 to 1885. Sir Robert Peel represented it during the first half of the 19th century. Tamworth, the centre of an agricultural and coal-mining area, specializes in agricultural engineering, textile weaving, paper making, the manufacture of asbestos and aluminum ware, and the making of terra cotta bricks from local clay.

TANA, a lake of northeast Africa, chief reservoir of the Abbai or Blue Nile. Tana lies between 11° 36′ and 12° 16′ N. and 37° 2′ and 37° 40′ E., about 6,000 ft. above the sea, on the northern portion of the Abyssinian plateau. Its greatest length is 53 mi., its greatest breadth 41 mi., and it covers 1,418 sq.mi. The shores are well defined, generally flat, but at places the mountains descend somewhat abruptly into the water. Elsewhere the land rises in gentle undulations, except at the mouths of the larger tributary streams, where are alluvial plains of considerable size. At the southeast end the lake forms a bay about 11 mi. long, and from 3 to 8 mi. across. From this bay the Abbai issues. The island of Dek (8 mi. long by 4 broad) is in the southwestern part, near the smaller island of Dega.

Lake Tana is fed by three large rivers and by many petty streams. The chief tributary is the Little Abbai, which enters the lake at its southwest corner. This river, and the Abbai itself or Blue Nile which issues from the lake, are regarded as one and the same stream and a current is observable from the inlet to the outlet. Next in importance of the affluents are the Reb and Gumara, which enter the lake on its eastern side. The outlet of the lake is marked by openings in a rocky ledge, through which the water pours by two or three channels, uniting within a couple of miles into one river—the Abbai with a width of 650 ft.

Tana has been identified with the *Coloe Palus* of the ancients, which was described by Ptolemy as a chief reservoir of the Egyptian Nile and the source of the *Astapos*, which was certainly the Blue Nile. In 1625 it was visited by the Portuguese priest Jeronimo Lobo, and in 1771 by James Bruce. It was formerly known by the name of Dembea. (C. F. R.)

TANA, a river 440 mi. long, in Kenya colony, which forms the northern boundary of Kenya protectorate (a coastal strip 10 mi. wide). Its sources are along the watershed close to the eastern wall of the eastern rift valley and it enters the Indian ocean in Formosa bay, at Kipini, in 2° 30′ S., about 120 mi. N. of Mombasa. One series of its numerous headstreams traverses the Kikuya plateau north of the Athi, others flow from Mount Kenya, all following a southeasterly direction until intercepted by the main stream which flows northeast until, when nearing the equator, it turns eastward, afterwards sweeping southward to the sea. It receives tributaries only along its upper course but on entering the plain it flows along a tortuous course, has low banks, and is in part forested and inundated at high water, but away from the river the country consists of dry plains covered with mimosa scrub. Five miles from the sea it divides in two, the southerly branch being the Sheriko. The Tana formerly entered the sea at Ozi creek, 20 mi. to the south of its present mouth. (S. M. C.)

TANAGER, the name for members of the songbird family Thraupidae (formerly Tanagridae) containing 197 species. They are small to medium-sized birds of rather generalized form, with medium-sized wings, feet and tails. The beak is heavy and somewhat similar to that of their nearest relatives, the sparrows. As a group tanagers are noted for the brilliancy of their plumage, though they have developed no ornamental tufts or plumes. Reds, yellows, greens, blues and blacks in solid colours are common and sometimes arranged in striking patterns. The sexes may be coloured similarly, or the female may be much duller than the male. In some species, however, both sexes are dull-coloured. No tanagers are notable songsters, but some have simple songs of pleasing quality.

The family is entirely confined to the new world, with its centre of abundance in the tropics. Only four species range north to the United States, and two regularly to Canada, and these are all migratory. Tanagers are arboreal birds, living in tree tops,

HAL H. HARRISON FROM NATIONAL AUDUBON SOCIETY

MALE SUMMER TANAGER (PIRANGA RUBRA) AND YOUNG

undergrowth or shrubbery. Fruit is an important part of the diet of many species, and some feed almost entirely on mistletoe berries. Other species eat some insects.

The nest is a shallow, open structure. The eggs, two to four in number, may be white or bluish, immaculate or spotted. Monogamous pairing seems the rule and, in some species at least, while the female alone incubates, both sexes care for the young. In the tropics some species remain in pairs throughout the year.

When feathers were popular in millinery, brilliant tropical tanagers were often used as hat trimmings.

The best-known species are probably those of the United States, especially the scarlet tanager (*Piranga olivacea*), the male scarlet with black wings and tail, the female olive and yellowish; the summer tanager (*Piranga rubra*), with an all-red male; and the western tanager (*Piranga ludoviciana*), with the male yellow with reddish head and black wings and mantle. (A. L. Rd.)

TANAKA GIICHI, Baron (1863–1929), Japanese statesman and general, born in Yamaguchi in 1863, graduated at the military cadet's school in 1886, and the staff college in 1892. He was minister of war in the Hara and Takahashi cabinets in 1918–21, and 1920. He became leader of the Seiyukwai Party in 1926, and formed a government in April 1927, himself taking the ministry of foreign affairs. He died on Sept. 28, 1929.

TANAQUIL, the Etruscan name of the wife of Tarquinius Priscus, or of one of his sons. After her immigration to Rome she is said to have received the name Gaia Caecilia. She was famous for her prophetic gifts. There was a statue of her as Gaia Caecilia in the temple of Sancus, which possessed magical powers. She was celebrated as a spinner of wool, and was supposed to exercise influence over Roman brides. Tanaquil and Gaia Caecilia are, however, really distinct personalities. The anecdotes told of Gaia Caecilia are etiological myths intended to explain certain usages at Roman marriages.

TANBARK OAK (*Lithocarpus densiflora*), an ornamental evergreen allied to the oaks, both of which belong to the beech family, Fagaceae. The tanbark oak, native to southern Oregon and northern California, is a tall tree of 75 to 100 ft., with alternate, leathery, toothed, more-or-less oblong three- to five-inch leaves covered on the underside with densely matted hairs that disappear in time.

The fruit is an acorn about one inch long. The tree is valued chiefly for its bark which is an important source of tannin, but it is also an attractive ornamental. (J. M. Bl.)

TANCRED (d. 1112), nephew of Bohemund I, took the Cross with Bohemund in 1096 and marched with him to Constantinople. Here he refused to take an oath to Alexius, escaping across the Bosporus in the disguise of a peasant; but after the capture of Nicaea he followed the example of the other princes and became the man of Alexius. At Heraclea, in the centre of Asia Minor, he left the main body of the crusaders and struck into Cilicia, closely followed by Baldwin of Lorraine. He made himself master of Tarsus and, when he was evicted from it by the superior forces of Baldwin, pushed further onward and took the towns of Adana and Mamistra. He joined the main army before Antioch and was prominent in the siege. He took part also in the siege and capture of Jerusalem (July 1099), after which he went to Nablus and began to found a principality of his own. He fought in the battle of Ascalon in August; and after it he was invested by Godfrey with Tiberias and the principality of Galilee, to the north of Nablus. In 1100 he attempted, without success, to prevent Baldwin of Lorraine (his old enemy in Cilicia) from acquiring the throne of Jerusalem. In the same year Bohemund I was captured by Moslems, and Tancred, relinquishing his lands in Galilee, went to act as regent in Antioch. In this capacity he regained the Cilician towns (1101) and recaptured Laodicea (1103). When Bohemund was set free, Tancred had to surrender Antioch to him. In 1104 he joined with Bohemund and Baldwin de Burg (now count of Edessa in succession to Baldwin of Lorraine) in an expedition against Harran, in which they were heavily defeated, and Baldwin was taken prisoner. Tancred, however, profited doubly by the defeat. He took over the government of Edessa in Baldwin's place, and in 1105 Bohemund surrendered to him the government of Antioch and went to Europe for reinforcements. Ruler of the two northern principalities, Tancred carried on vigorous hostilities against his Mohammedan neighbours, especially Ridwan of Aleppo; and in 1106 he captured Apamea. In 1107, while Bohemund was beginning his last expedition against Alexius, he again wrested the whole of Cilicia and Laodicea from the Greeks; and he steadfastly refused, after Bohemund's humiliating treaty at Deabolis in 1108, to agree to any of its stipulations with regard to Antioch and Cilicia. When Baldwin de Burg regained his liberty in 1108, it was only with difficulty that Tancred was induced to restore Edessa to him. But it was against the amirs of northern Syria that his arms were chiefly directed. Tancred died in 1112.

TANCRED (d. 1194), king of Sicily, an illegitimate son of Roger the eldest son of King Roger II, was crowned in January 1190 in succession to William II (*q.v.*). He was supported by the chancellor Matthew d'Ajello and the official class, while the rival claims of Roger II's daughter Constance and her husband, Henry VI, king of the Romans and emperor, were supported by most of the nobles. Tancred was a good soldier; but he was ill-supported in his task of maintaining the Norman kingdom, faced with general apathy, threatened by a baronial revolt, and menaced by Richard Coeur-de-Lion, at Messina, 1190. Henry, skilfully winning over Pisa, Genoa and the Roman Commune, isolated Tancred and intimidated Celestine III, who, on April 14, 1191, crowned him emperor at Rome. He, however, failed to capture Naples in August and retired north, leaving garrisons along the frontiers of the Regno. Tancred now sought to win over the towns by extensive grants of privileges, and at Gravina (June 1192) was recognized by the pope, whose ineffectual support he gained by surrendering the royal legateship over Sicily. In 1192 and 1193 he successfully opposed the Apulian barons, but his death at Palermo (Feb. 20, 1194) a few days after that of Roger, his son and joint king, made Henry's path clear.

TANDY, JAMES NAPPER (1740–1803), United Irishman, born in Dublin in 1740, was a prominent reformer and supporter of Lucas and Grattan. He first won popularity by his attacks on municipal corruption and his proposal to boycott English goods in retaliation for the restrictions imposed on Irish commerce. In 1780 Tandy was expelled from the Dublin volunteers (*see* Flood, Henry), but he continued his revolutionary agitation, and in 1791 co-operated with Wolfe Tone in founding the Society of United Irishmen, of which he became the first secretary. A challenge sent to the attorney general resulted in his imprisonment (1792), but on his release Tandy assisted in raising two battalions of a "national guard," which were suppressed. He then fled to America, and in 1798 proceeded to France, where he joined a number of Irish refugees. Having gained the ear of the French government, Tandy was given command of a cor-

vette, a small force of men, and a quantity of arms for distribution in Ireland. Arriving at Donegal, however, he learned that Humbert's expedition had failed, and he thereupon fled to Hamburg. The refugees were surrendered on a peremptory demand from the British government. Condemned to death, he was finally reprieved due, it is said, to Bonaparte's intercession.

Tandy's exploits completely captured the popular imagination, and he is still remembered as the hero of the "Wearing of the Green." He died in France on Aug. 24, 1803.

TANEIEV, SERGIUS (1856–1915), Russian composer and theorist, was born on Nov. 13, 1856, in the Vladimir government. He studied under Nicholas Rubinstein and Tchaikovsky at the Moscow conservatory. After a short career as a concert pianist he went back to Moscow as professor of instrumentation, then first professor of pianoforte and, in 1885, director. He died at Moscow on June 15, 1915. His published works include a symphony; five string quartets; a dramatic work, *Orestes* (performed in St. Petersburg 1895); a cantata, *John of Damascus;* and choruses for male voices and for mixed voices. He also wrote a treatise on counterpoint.

TANEY, ROGER BROOKE (1777–1864), fifth chief justice of the United States, whose decision in the Dred Scott case in 1857 became a centre of violent controversy, was born March 17, 1777, in Calvert county, Md. His father was a member of a family of planters and he inherited the conservative tradition of the landed aristocracy of the south. His education in rural schools was supplemented by a family tutor and by three years of instruction at Dickinson college, from which he graduated in 1795. Since as a second son Taney would not inherit the family plantation, he was trained for a legal and political career. He studied law at Annapolis under Judge Jeremiah T. Chase of the Maryland general court and was admitted to the bar in 1799.

In 1801 Taney settled in Frederick, Md., where he established himself as an able lawyer, achieved a position of prominence in political affairs and raised a family. His marriage in 1806 to Anne Key, sister of Francis Scott Key, was a happy one and resulted in six daughters. Although his practice was demanding and his health frail, Taney found time for political activity, serving several terms in the Maryland legislature and gradually working his way into the leadership of the Federalist party in the state.

When the War of 1812 split the Federalist party (*q.v.*), Taney, a representative of inland agrarian interests, became the leader of the group, derisively referred to as "Coodies," which supported the conduct of the war. Although the former Federalists cooperated after the war on certain matters of state politics, the breakdown of the Federalist organization left Taney without party affiliation. In the 1820s he aligned himself with Andrew Jackson and thereafter was found in the ranks of the Democrats. This transition was not unnatural since Jackson, like Taney, was a slaveowner and a member of the landed aristocracy, and they shared many of the same views.

In 1823 Taney moved to Baltimore, where professional opportunities were greater, and was soon recognized as a leader of the Maryland bar. His extensive practice broadened his knowledge of the law and gave him wide acquaintance with the economic developments of his time. In 1827 he was appointed attorney general of Maryland, an appointment which honoured his legal attainment while allowing him to continue his private practice.

Taney became a national figure as a result of his participation in the bank war of the 1830s. When Jackson reorganized his cabinet in 1831, Taney accepted an appointment as attorney general. At that time the Bank of the United States, chartered by congress in 1816, had attained a dominant position in American finance and sought to exercise its influence in order to force immediately the renewal of its charter which was to expire in 1836. Although Taney had once regarded a national bank as a desirable instrument for regulating the currency, his experience with the activities of the Bank of the United States convinced him that the bank had abused its powers. When in 1832 congress enacted a bill to renew the charter, Taney persuaded Jackson to veto it and wrote much of Jackson's veto message.

In the ensuing presidential campaign the bank took an active part, financing its supporters and attempting to frighten its opponents by manipulating the credit structure. The revelation of these events after Jackson's re-election in 1832 led Taney and others to advise Jackson to withdraw government deposits from the Bank of the United States and place them in selected state banks. Jackson delayed action for a number of months but eventually in 1833 ordered William J. Duane, then secretary of the treasury, to remove the deposits. When Duane refused, Jackson dismissed him and gave Taney a recess appointment as secretary of the treasury. Taney's subsequent action in removing government deposits to a number of state banks was subjected to virulent partisan attack, much of which was undeserved since the bank had engaged in political and financial activities of questionable character. Nevertheless, Taney's attempt to improve and regulate the currency through a system of state banks proved ineffective, in part because congress failed to enact implementing legislation. Although the bank was not rechartered, opposition to Taney and his financial program was so strong that his appointment as secretary of the treasury was rejected by the senate when it was presented for confirmation. Three years of cabinet service, during nine months of which he held a recess appointment as secretary of the treasury, thus ended, and Taney returned to private life and attempted to rebuild his law practice.

In 1836, at the age of 59, Taney began the last and greatest phase of his career. As a reward for his political loyalty, Jackson appointed him chief justice of the United States to succeed the celebrated Federalist John Marshall. Despite Whig opposition, Taney was confirmed by the senate and took the seat he was to hold for nearly three decades (1836–64). His appointment coincided with change and expansion in the personnel of the court, with the result that by 1837 all but two of the nine judges were appointees of Jackson or Van Buren. This change alarmed those who feared that property rights would be at the mercy of state legislatures. Although the Taney court did give greater scope to the exercise of state power than had the Marshall court, it was no less vigilant in maintaining federal supremacy until it foundered on the constitutional questions presented by Negro slavery.

In his first great judicial utterance, *Charles River Bridge* v. *Warren Bridge*, 11 Pet. 420 (1837), Taney expressed his deeply-held conviction that the powers conferred by corporate charters should be given a narrow interpretation in order to preserve the rights of the community. Speaking for a majority of the court, he rejected the claim of a bridge company that the subsequent grant by the state legislature of a charter to another bridge company impaired the obligation of contracts. The same emphasis on the rights of the community pervaded Taney's opinions dealing with the impact of the commerce clause on state regulatory legislation. He was unwilling to use the commerce clause as an instrument to defeat state regulation; *e.g., License Cases*, 5 How. 504 (1847), *Passenger Cases*, 7 How. 283 (1849), dissenting opinion. While he concurred in several opinions upholding state regulation on a police power rationale, his own view appears to have been that the states, in the absence of federal legislation, remained free to regulate commerce.

Despite his willingness to sustain state authority against constitutional attack, Taney's court cannot be characterized as interested only in "states' rights." Whenever state authorities threatened or interfered with the exertion of federal power, Taney was firm in upholding federal supremacy. His opinion in *Ableman* v. *Booth*, 21 How. 506 (1858), denying state power to obstruct the processes of the federal courts, remains a magnificent statement of constitutional federalism. Under Taney's leadership, federal judicial power was expanded over corporations; the admiralty jurisdiction was extended to inland waters; the federal government was held to have a paramount and exclusive authority over foreign relations; and congressional authority over U.S. property and territory was vigorously upheld.

Until the mid-1850s the court avoided embroilment in the controversy over slavery which was constantly increasing in bitter-

ness. As late as 1850, in *Strader* v. *Graham*, 10 How. 82, Taney succeeded in disposing of important constitutional questions relating to slavery on a narrow jurisdictional ground. However, by 1856 the prestige of the court was thought so great and the issue so momentous that the court was urged to settle the question whether congress had power to restrict slavery in the territories. In the Dred Scott case, 19 How. 393 (1856), one of the great "self-inflicted wounds" of the supreme court, the court yielded to the temptation to solve this fundamental political controversy by constitutional decision. Taney, writing for a majority of the court, held that Negroes could not possess rights of citizenship entitling them to sue in federal courts; that the removal of a slave to a territory in which congress, by the Missouri compromise, had prohibited the holding and owning of slaves did not result in freedom because congress lacked such power; and, finally, that the return of a Negro to a state recognizing him as a slave was conclusive as to his status. On the facts of the Dred Scott case, the third and narrowest ground was sufficient to dispose of the case. Taney's further holdings, that congress had no power to exclude slavery from the territories and that Negroes could not be citizens, were disputed by vigorous dissenting opinions and were bitterly attacked by the northern press. The decision became an issue in national politics and, with the victory of the Republicans in 1860, the prestige of the court reached the lowest point in its history. Taney's attachment for southern culture thus resulted in an unsuccessful attempt to safeguard that culture from the legislative power of the northern majority.

Taney's last years were spent in futility and despair. His background led him to sympathize with the south and he hoped that the south would be allowed to secede peacefully. During the war the court, though it continued to function as part of the government, was suspected of disloyalty. Taney, believing that war issues might come before the court, prepared in the privacy of his study a series of opinions in which he found various war measures unconstitutional. *Ex parte Merryman*, Fed. Cases no. 9,487 (1861), containing a vigorous defense of the rights of civilians in war time, is the only one of those opinions to be found in the reports. Taney's death in Washington on Oct. 12, 1864, went largely unnoticed and unregretted.

Taney's relations with his family and his associates were warm and pleasant. Not an effective platform speaker, he was at his best in personal association, where his warmth, kindness and quiet charm quickly resulted in intimacy. He presided over the supreme court with dignity and courtesy, and his personal qualities, so his colleagues have testified, led to greater unity on the court than otherwise would have occurred. His legal abilities were of the highest order, as his concise, persuasive opinions indicate. Although a devout Roman Catholic, he refused to allow members of his faith to prosyletize among his wife and daughters, who with one exception were Protestants.

Any evaluation of Taney is complicated by the fact that his actions and attitudes affecting slavery and national unity are part of the tradition defeated in the Civil War. Yet his outstanding abilities had a lasting influence on the content and development of American constitutional law.

T'ANG, the dynasty that ruled China from A.D. 618 to 907. The first emperor Li Yuan (or Kao-tsu, 618–626) was a member of the aristocracy of part-barbarian, part-Chinese origin, that had formed the governing class in the Northern Chou state, centred on Ch'ang-an in the 6th century, as well as in the Sui dynasty (A.D. 589–618). Li Yuan's success in obtaining the throne at the end of the Sui dynasty was largely due to his second son, Li Shih-min (or T'ai-tsung, 626–649), who succeeded him.

T'ai-tsung was succeeded by his son Kao-tsung (649–683), who soon fell under the domination of one of the most remarkable women in Chinese history, Wu Tse-t'ien or Empress Wu. She became the real power in the land even during her weak husband's lifetime. After his death she deposed her two sons in succession and ruled in her own name, a thing never achieved before or since in China. She changed the dynastic name to Chou but insured the eventual restoration of T'ang when invasions of the Khitans and Turks in the northeast necessitated an appeal to the people's loyalty.

During the reign of Kao-tsung the T'ang empire completed, at great cost, the conquest of northern Korea. But after *c.* 682 the northern Turks revolted, following 50 years of submission, and the Four Garrisons in Sinkiang were lost to the Tibetans. Also the Korean conquests were swallowed up by T'ang's erstwhile ally, the southern Korean state of Silla, which united the peninsula for the first time.

The aged empress's forced abdication in 705 was followed by an unstable period during which her two sons, Chung-tsung (705–710) and Jui-tsung (710–712), followed one another on the throne but were dominated by cliques centred around the empress of the former, surnamed Wei, and their sister, the T'ai-p'ing Princess. Successive *coups d'état* finally led to Jui-tsung's abdication in favour of his son, known as Ming Huang the Brilliant Emperor (alias Hsuan-tsung, 712–756). His reign, the longest in the dynasty, was also its high point of prosperity. With the help of able ministers he corrected administrative abuses that had grown up in the previous decade but efforts at fiscal reform, mainly carried out by special commissioners of aristocratic background, conflicted with the interests of the rising new landowning class. A political struggle ensued which resulted in the virtual dictatorship of the imperial kinsman Li Lin-fu, from 736 onward, after which the emperor withdrew into a life of pleasure.

Under Ming Huang the Chinese once more expanded on all fronts but at the cost of establishing large standing armies composed to a dangerous extent of non-Chinese troops. In the years 751–754 the Chinese suffered defeats in Manchuria; at the battle of Talas against the Arabs in central Asia; and especially against the state of Nan Chao in Yunnan. Real disaster struck in 755 with the revolt of the commander of the northeast sector of the frontier. This was An Lu-shan, of part-Sogdian and part-Turkish origin, who owed his promotion, like the barbarian generals in other sectors, to Li Lin-fu's fear of Chinese rivals.

The rebels captured the capital and drove the emperor to flight. The crown prince (Su-tsung, 756–762), who assumed the throne in the northwest succeeded, with the aid of a contingent of Uighur troops, in recapturing Ch'ang-an and Lo-yang. But the T'ang forces lacked strength to complete their victory and the war dragged on inconclusively until 762 when the last rebel pretender was killed. The northeastern provinces remained in control of former rebel generals who were acknowledged as T'ang governors; much of the rest of the country was in the hands of military leaders who were often as insubordinate as the former rebels. In the west the Tibetans, now at the height of their power, occupied large areas and in 763 they even briefly occupied Ch'ang-an. In the north, T'ang's allies, the Uighurs, were almost as oppressive as the Tibetans. The disruption of government by the rebellion led the emperors to place increasing reliance on their personal attendants, the palace eunuchs, who were given control of the palace armies.

During the reigns of Tai-tsung (762–779) and Te-tsung (779–805) the policy of the T'ang court was mainly a negative one of trying to control the militarists by diplomacy while the country slowly recovered from the effects of war. During the brief interlude of Shun-tsung's reign in 805 a reform party tried unsuccessfully to take the palace armies out of the hands of the eunuchs, who thereafter controlled the person of the sovereign, setting up and removing emperors as they pleased.

Under Hsien-tsung (805–820) some success was achieved in asserting central authority over the provinces but it was not lasting, and the northeast remained effectively autonomous to the end of the dynasty.

Hsien-tsung was murdered by eunuchs and the short reigns of Mu-tsung (820–824) and Ching-tsung (824–827) followed. Wen-tsung (827–840) plotted with his ministers to deprive the eunuchs of their military power but the plan misfired and resulted in the

Sweet Dew incident of 833 in which three chief ministers and many other officials were slaughtered. Under Wu-tsung (840–846) the simultaneous decline of the Tibetan and Uighur empires eased the pressure on the northern and western frontiers. This was followed by the persecution of the Manichaean church in China, which had enjoyed Uighur protection, and this in turn led on to an unparalleled suppression of Buddhist monasteries and laicization of monks and nuns, a blow from which Chinese Buddhism never fully recovered.

The reign of Hsuan-tsung (846–859) was outwardly calm except for wars with Nan Chao in the south, but the demoralization of the central government and the lawlessness of the provincial armies and their leaders made the dynasty quite incapable of dealing with the disturbances, provoked to a large extent by maladministration and corruption, which broke out in an ever-rising crescendo under I-tsung (859–873) and Hsi-tsung (873–888). In 875 began the great peasant uprising known as the Huang Ch'ao rebellion, led by former salt smugglers. After roaming up and down the country for years the rebels occupied Ch'ang-an in 881. They were unable to organize the food supply of the capital and this, together with the intervention of Sha-t'o Turks, forced Huang Ch'ao to flee east in 883, where he was caught and killed.

From then on, while lawless bands terrorized the countryside, the T'ang court could only survive by playing off one military governor against another. In 903 Chu Ch'üan-chung, one of Huang Ch'ao's officers who had surrendered opportunely and obtained the governorship of the strategic region of K'ai-feng, gained control of the person of the T'ang emperor Chao-tsung (888–904). He settled the eunuch problem by a wholesale massacre. After his men had murdered Chao-tsung in 904 he placed a boy of thirteen (Chao-hsuan-ti) on the throne who was presently put through the motions of abdication. Chu Ch'üan-tsung ruled over part of north China as T'ai-tsu of Later Liang (907–915). China fell apart into a number of independent kingdoms, and unity was not restored until after the founding of Sung (*q.v.*) in 960: *See* also CHINA: *History*.

Social and Economic Life.—During T'ang the economic centre of gravity of China shifted from the Yellow River plain to the Yangtze. The population of the latter region increased enormously, swollen by influxes of refugees from the north, especially after the rebellion of An Lu-shan. The canal system built by Yang-ti of Sui became the lifeline of the capital, especially after the efficiency of the transport system had been improved in the reign of Ming Huang and again under Tai-tsung. Trade, both internal and external, was stimulated by the unification of the country and its far-flung conquests. Much of this trade was in the hands of foreigners, particularly Iranians, who settled in large communities in the major cities. They came both by land through central Asia and by sea to Canton. Especially during the first half of the dynasty China was very receptive to foreign ideas. Foreign music and dancing were popular, and foreign types are common among the familiar T'ang pottery figurines.

Migration and economic development led to a breakdown in the system of state registration of population and distribution of land and to the growth of private estates. After the An Lu-shan rebellion the old system was finally abandoned and direct taxation was based on actual land under cultivation and on an assessment of the wealth of the household. The salt monopoly, introduced as an emergency war measure during the rebellion, became a major source of government revenue and continued into the 20th century. The increase in trade led to a need for coinage; as the government mints were unable to produce an adequate supply, counterfeiting was a chronic problem. The shortage of cash and the difficulty of transporting the bulky copper coins encouraged the development of credit instruments such as the so-called "flying money," a kind of bank draft. True paper money did not appear until the 10th century.

Society remained decidedly aristocratic but economic expansion led to the creation of a more broadly based landowning class. These new men began to push their way into the government by means of the examination system, which, although a development from earlier institutions, really began in Sui and T'ang. Empress Wu, especially, used it to undermine the position of the aristocratic clans. The competition between aristocratic privilege and the ideal of selection by merit continued throughout the dynasty.

Religion and the Arts.—The T'ang emperors officially supported Taoism because of their claim to be descended from Lao-tzu, but Buddhism continued to enjoy great favour through most of the period, especially under Empress Wu. The famous pilgrim, Hsuan-tsang, who went to India in 629 and returned in 645, was the most learned of Chinese monks and introduced new standards of exactness in his many translations from Sanskrit. In spite of such direct Indian influences through Indian teachers in China as well as Chinese pilgrims to India, the most significant development in T'ang was the growth of new indigenous schools which adapted Buddhism to Chinese ways of thinking. Most prominent were the syncretic T'ien-t'ai school which sought to embrace all other schools in a single hierarchical system, even reaching out to include Confucianism as well, and the radically antitextual, antimetaphysical Southern Ch'an (Zen) school which had strong roots in Taoism. The popular preaching of the salvationist Pure Land sect was also important. After the rebellion of An Lu-shan a nationalistic movement in favour of Confucianism appeared, merging with the efforts of T'ien-t'ai Buddhism to graft Buddhist metaphysics on to classical doctrine and lay the groundwork for the Neo-Confucianism of Sung.

In literature the greatest glory of the T'ang period was its poetry. By the 8th century poets had broken away from the artificial diction and matter of the court poetry of the Southern Dynasties and achieved a new directness and naturalism. The great flowering came in the reign of Ming Huang, the time of the great figures of Li Po (701–762), Wang Wei (698–759) and Tu Fu (713–770), besides a host of lesser names. The rebellion of An Lu-shan and his own bitter experiences in it brought a new note of social awareness into the later poetry of Tu Fu. This appears again in the work of Po Chü-i (772–846) who wrote verse in clear and simple language. Toward the end of the dynasty a new poetic form, the *tz'u*, in a less regular metre than the five-word and seven-word *shih*, and meant to be sung, made its appearance. The *ku-wen* or "ancient style" movement grew up after the rebellion of An Lu-shan, seeking to replace the euphuistic "parallel prose" then dominant. It was closely associated with the movement for a Confucian revival. The most prominent figures in it were Han Yü (768–824) and Liu Tsung-yuan (773–819). At the same time came the first serious attempts to write fiction, the so-called *ch'uan-ch'i* or "tales of marvels." Many of these T'ang stories later provided themes for the Chinese drama.

The patronage of the T'ang emperors and the general wealth and prosperity of the period encouraged the development of the visual arts. Though few T'ang buildings remain standing, contemporary descriptions give some idea of the magnificence of T'ang palaces and religious edifices and the houses of the wealthy. Buddhist sculpture shows a greater naturalism than in the previous period but there is some loss of spirituality. Few genuine originals survive to show the work of T'ang master painters such as Wu Tao-hsuan (*c.* 700–760) who worked at Ming-huang's court. As a landscape painter the poet Wang Wei was a forerunner of the *wen-jen* or "literary man's" school of mystical nature painting of later times. The minor arts of T'ang, ceramics, metalwork, textiles, etc., give expression to the colour and vitality of the life of the period. Printing appeared for the first time during T'ang. Apparently invented to multiply Buddhist scriptures, it was being used, by the end of the dynasty, for such things as calendars, almanacs and dictionaries. The first printing of the Confucian classics came after the end of the dynasty in 932 in Szechwan.

TANGANYIKA, a republic in east central Africa within the Commonwealth of Nations that merged with Zanzibar in April 1964 to form a single sovereign state, the United Republic of Tanzania (*q.v.*). It is bounded east by the Indian Ocean, south and southwest by Mozambique (Portuguese East Africa), Malawi,

and Zambia, west by the Democratic Republic of the Congo, Rwanda, and Burundi, and north by Uganda and Kenya. Mafia Island is included in Tanganyika. The total area of 361,800 sq.mi. (937,052 sq.km.) includes 20,650 sq.mi. (53,484 sq.km.) of inland water. The capital is Dar es Salaam (*q.v.*).

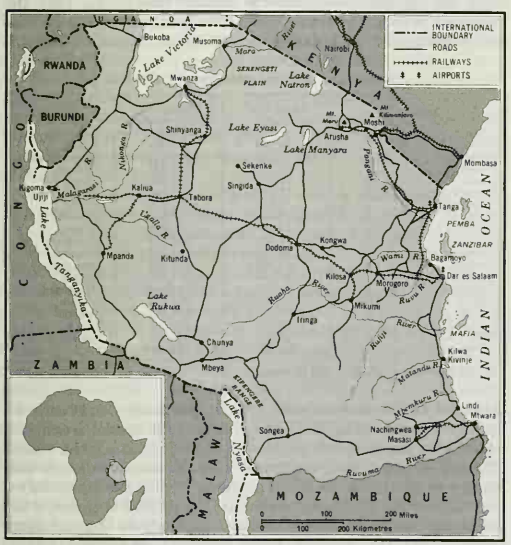
PHYSICAL GEOGRAPHY

Geology.—Most of Tanganyika is composed of ancient crystalline rocks (Archean and Proterozoic). The oldest, those of the Dodoman System of the Central Plateau, probably form a rigid shield under rocks of later age. Banded ironstones and other volcanics of the Nyanzian and Kavirondian systems with extensive granite emplacements are found to the north, while to the west and east are metamorphosed sedimentary and volcanic rocks of the Ubendean and Usagaran systems, respectively, which, with the Dodoman System, were formerly grouped under the term Basement. In the extreme west are found metamorphic rocks of sedimentary origin (Karagwe-Ankolean), intrusive granites with associated tin and wolfram, and the sediments and lavas of the Bukoban System.

Karroo beds (Upper Carboniferous—Lower Jurassic) preserved in faulted basins in the south and southwest contain Coal Measures. Younger sedimentary rocks (marls, limestones, sandstones, and shales) deposited from Jurassic to Recent times form a belt between the plateau and the coast, while lake and river sediments have been laid down inland since Pleistocene times. What are believed to be the earliest known remains of man (*Zinjanthropus boisei*) were in 1959 found in such deposits in Olduwai Gorge.

Volcanic activity associated with rift faulting occurred from Late Cretaceous times, in the southwest around Mt. Rungwe in the Rukwa-Nyasa Rift, and in the north resulting in the immense volcanic massifs and lava flows from Mt. Hanang to Kilimanjaro. Ol Doinyo (Oldongo) Lengai Volcano, near the Kenya border, was active in the 1950s.

Relief and Drainage.—The greater part of Tanganyika consists of an immense plateau varying in altitude from 3,500 to 4,500 ft. (1,070 to 1,370 m.). To the west it is bounded by steep escarpments of the western arm of the Great Rift Valley, which contains Lakes Tanganyika, Rukwa, and, outside the territory, Lakes Kivu, Edward, and Albert. The valley forks north of Lake Nyasa, and the eastern arm, which passes through the centre of Tanganyika, is less distinct; only the western wall is seen, as a cliff of varying height, until the troughlike characteristics of the Gregory Rift become noticeable near Kenya.



TOWNS AND TRANSPORTATION ROUTES IN TANGANYIKA

The mountain systems are grouped in the northeast and southwest, with a ridge of highland between the two forming the eastern margin of the plateau. In the north are the volcanic peaks of Kilimanjaro (19,340 ft. [5,895 m.]) and Meru (14,979 ft. [4,566 m.]), and the Crater Highlands, with the famous game-filled Ngorongoro caldera. Running southeast from Kilimanjaro to the coast are the Pare and Usambara ranges, while the Nguru and Uluguru mountains rise behind the coastal plain farther south. At the northern end of Lake Nyasa are the Livingstone Mountains, the Kipengere Range, the Poroto Mountains, Mt. Rungwe, and, farther west, the Ufipa Plateau.

Although appearing well watered on the map, Tanganyika has few permanent rivers, and most of the Central Plateau is devoid of running water throughout the dry season; only half the country is supplied with natural water throughout the year. The main rivers flowing to the Indian Ocean are: the Pangani, or Ruvu, which rises on Kilimanjaro; the Wami, whose tributary the Kinyasungwe-Mukondokwa has cut back into the plateau edge to capture some of the drainage of the interior; the Kingoni, or Mto Ruvu; the Rufiji, whose many tributaries include the Ruaha, which has also cut back through the plateau edge, the Kilombero, the Luwegu, and the Mbarangandu; and, farther south, the Matandu, Mbemkuru, Lukuledi, and the Ruvuma, which forms the southern boundary of the country.

The Mara, Kagera, and other rivers flow into Lake Victoria, the Malagarasi into Lake Tanganyika, and the Songwe and Ruhuhu into Lake Nyasa. Thus, Tanganyika forms the divide separating the headwaters of the three greatest rivers of Africa—the Nile, Congo, and Zambezi—flowing, respectively, into the Mediterranean, the Atlantic, and the Indian oceans. Between these systems are two great dischargeless basins. The Wembere, Manonga, and Sibiti, which have a seasonal flow only, drain much of the eastern side of the Central Plateau into Lake Eyasi, a salt lake in a subsidiary trough of the eastern Great Rift Valley, where Lakes Natron and Manyara are also salt. In the southwest the Rungwa River drains into another dischargeless salt lake, Rukwa. About half of the great lakes Tanganyika and Victoria lie within the Tanganyikan borders, but Lake Nyasa is wholly outside the country.

Climate.—The climate is characterized by alternating wet and dry seasons. The small seasonal variation in temperature is much exceeded by the diurnal range, which is greatest over the Central Plateau (as much as 20° C [36° F]) and least in coastal and lake regions (about 8° C [14.4° F]). Afternoon temperatures above 32° C (89.6° F) may prevail during the hottest months, from October to May. The equatorial climate is modified by decreased temperatures over the high plateaus and mountains, giving a range of climates from the hot, humid coastal belt to regions of snow and ice on Kilimanjaro.

The rainy season is from November or December to April or May, when humidities may be uncomfortably high near the coast, with drought for the rest of the year. But the Kenya pattern of long and short rains prevails in northeastern Tanganyika, where the main rains are during March–May and the short rains in November–December. Rainfall is broadly associated with seasonal oscillations of the convergence zone between the southeast monsoon, prevailing at the coast from April to October, and the northeast monsoon, prevailing from November to March.

Much of the territory is semiarid. Three regions can be distinguished: a coastal belt with a mean annual rainfall of 30–40 in. (760–1,000 mm.); a dry zone across the Masai Steppe and Eastern Plateau with less than 30 in.; and a wetter region with more than 30 in. in the west, but where seasonal drought is still severe. Increasingly heavy orographic rainfall occurs on windward slopes up to about 8,000 ft. (2,400 m.) (more than 70 in. [1,800 mm.] on Kilimanjaro). Very heavy rain falls at the northern end of Lake Nyasa (more than 100 in. [2,500 mm.]) and on the western shore of Lake Victoria (more than 80 in. [2,000 mm.]), where storms off the lake are concentrated by the prevailing winds. High evaporation rates limit the effectiveness of the rainfall.

Annual variations are considerable, and because of unreliable rainfall extensive areas are suited only to pastoral development.

Soil and Vegetation.—Soil types include those of the plateaus, with a horizon of concretionary ironstone (murram), deep red earths, volcanic soils, calcareous black soils, sandy soils, and alluvial soils. With some exceptions, soils are poor, deficient in plant nutrients, and easily leached. Accelerated soil erosion is a serious problem.

Miombo woodland (*Isoberlinia-Brachystegia*) occupies extensive areas in the west and south, and on open steppes grow scattered *Acacia* and myrrh tree (*Commiphora*). The grotesque baobab and symmetrical *Euphorbia candelabra* are also characteristic. Evergreen forest, in which *Podocarpus* (yellowwood), *Chlorophora excelsa* (muvule, muule, or iroko), and various cedars are of economic value, occurs on mountain slopes. Above the forest, bamboo sometimes occurs, and open woodland with giant heathers. Higher still, Afro-alpine tree communities include giant species of *Senecio* (groundsel) and *Lobelia*. Coconut palms and casuarinas abound near the coast, and extensive mangrove swamps south from the Rufiji Delta.

Animal Life.—The country is unsurpassed in the number and variety of its wildlife: elephant, giraffe, zebra, rhinoceros, buffalo, together with lion, leopard, cheeta, hyena, and other carnivores; numerous varieties of antelope, including impala, gazelle, and wildebeest; snakes, lizards, chameleons, crocodiles, and other reptiles; and more than 1,000 varieties of birds, including game birds. Chimpanzees are found in the mountains east of Lake Tanganyika. The sitatunga is found in certain swamps, and the gerenuk (another rare antelope) in the Arusha, Kilimanjaro, and Tanga regions.

The Serengeti National Park (4,450 sq.mi. [11,526 sq.km.]) is the most important reservation for plains game in Africa; it no longer includes the Ngorongoro caldera, which has become a separate conservation unit. Other, smaller national parks are those of Ngurdoto Crater, near Arusha, and Lake Manyara. Of the game reservations the largest are the Selous and Rungwa River; smaller ones include the whole areas of Mt. Kilimanjaro and Mt. Meru and others at Lake Natron and Katavi Swamp. The Rukwa Valley is one of the swarming areas of the locust, and game conservation there is administered by the Red Locust Research Association. Some of the game reservations have suffered from poaching and insufficient supervision, but at a conference on wildlife conservation held at Arusha in 1961 the Tanganyikan government announced a conservation policy more advanced than that adopted by any other African state. The tsetse fly (chiefly *Glossina morsitans*) infests wide areas, spreading sleeping sickness, but is being steadily eradicated by tree clearance and the establishment of permanent farms. Rainbow and brown trout were introduced into rivers of the northern and southern highlands, and Nile perch and tiger fish are caught in Lake Tanganyika. From November to March coastal big-game fishing is popular off Tanga and Mafia. (J. M. Ke.)

THE PEOPLE

Most of the peoples of Tanganyika are Bantu-speaking Negroes. They are among the northernmost Bantu peoples and were subjected to non-Bantu invasions from the north and to Arab contact from the coast. In the north and west are the southerly Interlacustrine Bantu kingdoms of Ha (numbering about 290,000), Haya (325,000), Fipa (80,000), and the smaller Kerewe, Zinza, Subi, and others. (*See* Bantu [Interlacustrine].) There are about 120 different tribes, and several of the large ones have been affected by the Interlacustrine invasions, notably the Sukuma south of Lake Victoria (more than 1,000,000) and the Nyamwezi in west Tanganyika (363,000). In the south, tribes related to those of Zambia and Malawi include the Nyakyusa (220,000), Bena (196,000), and the Ngoni and Yao (*qq.v.*). In the centre and north most Bantu tribes have been influenced culturally by the Masai (*q.v.*); they include the Gogo in the Dodoma Region (299,000), Hehe (*q.v.*; 220,000), Arusha (68,000), Kuria (65,000), and Nyaturu (185,000). In the northeast dwell several tribes closely related to the Kikuyu and Kamba of Kenya, including the Chagga around Mt. Kilimanjaro (more than 300,000), Sambaa (194,000), and Pare (126,000). In the east and southeast are tribes who, unlike the others, reckon descent matrilineally and have been affected by Arab influence; among these are the Makonde of the Mtwara Region (334,000), Luguru (202,000), Zaramo (183,000), Mwera (138,000), Zigua (134,000), Makua (123,000), and Rufiji (75,000).

The Great Rift Valley area in the north seems to have been a refuge for a cluster of non-Bantu tribes who were left unaffected by the many migrations of Bantu Negroes. The Hadzapi or Kindiga, hunters and gatherers reputedly related to the Bushmen of southern Africa, live on the Lake Eyasi flats; the pastoral Sandawe are said to be related to the Hottentots. These two groups are probably remnants of earlier populations. The Iraqw (134,000) and some small outlying groups are linguistically unrelated to any other known peoples; their language may have Cushitic affinities. There are also in the north about 50,000 Masai and 30,000 Barabaig, Nilo-Hamitic speakers, who migrated from Kenya, and who, as warrior tribes, greatly influenced their neighbours.

Apart from the Hadzapi, Sandawe, Masai, and Barabaig, all the tribes are agriculturalists, traditionally growing maize (corn) and millets. Save for the few kingdoms or chiefdoms (Ha, Fipa, Chagga), these peoples lack centralized political authority; their density of population and political cohesion are low. Except on the coast and in some older inland towns, where Islam predominates, the population is generally animist, although Christianity through missionary activity has made some headway. Arab contact on the coast dates from about the 5th century A.D.; many small Arab city-states were founded on trade in slaves, ivory, and gold. The slave trade, later based on Zanzibar, had devastating effects throughout central and southern Tanganyika, much of which remains thinly populated. (J. F. M. M.)

Population.—The population is unevenly distributed. One-quarter of the African peoples dwell around the shores of Lake Victoria; other large concentrations are in the highlands (especially Mt. Kilimanjaro) and the coastal towns. In 1963 the estimated population totaled 9,683,700, including 90,500 Indians and Pakistanis, 27,600 Arabs, and 22,700 Europeans. The Indians and Pakistanis are chiefly artisans and traders and nearly all live in the towns. The Arabs live mostly in the coastal areas, with a few in the Kigoma, Tabora, Dodoma, and Singida regions. Most of the Europeans are government officials, missionaries, or employees on plantations or in industrial or trading concerns; only a few hundred are permanent settlers. The Swahili language is the lingua franca. The principal townships apart from Dar es Salaam (pop. [1957] 128,742) are Tanga (38,053), Mwanza (19,877), Tabora (15,361), Morogoro (14,507), Moshi (13,726), and Dodoma (13,435).

Tanganyika: Regions and Regional Capitals

Region	Land Area (sq.mi.)	Population (1957 census)	Capital
Arusha	31,900	407,483	Arusha
Coast	13,050	537,012	Dar es Salaam
Dodoma	16,350	514,425	Dodoma
Iringa	21,750	489,291	Iringa
Kigoma	17,100	382,505	Kigoma
Kilimanjaro	5,150	473,859	Moshi
Mara	11,000	347,587	Musoma
Mbeya	23,650	540,978	Mbeya
Morogoro	28,400	547,558	Morogoro
Mtwara	32,050	747,232	Mtwara
Mwanza	13,300	836,341	Mwanza
Ruvuma	23,550	267,033	Songea
Shinyanga	19,850	660,441	Shinyanga
Singida	18,850	372,587	Singida
Tabora	59,650	567,518	Tabora
Tanga	10,850	579,382	Tanga
West Lake	15,350	514,431	Bukoba
Total	361,800	8,788,466*	

*Total population includes 2,853 in transit.

In the 1960s the African population was increasing at an average rate of nearly 2% annually, though in some of the highland tribes the increase was more rapid. The Asian communities had a higher rate of natural increase (about 2.5%). The growth of the European population was largely determined by net immigration. (J. P. Mt.; J. M. Ke.)

HISTORY

Early History and Exploration.—Most of the known history of Tanganyika before the 19th century concerns the coastal area, although the interior has a number of important prehistoric sites (*see* the East African subsections of *History* and *Archaeology* in AFRICA). Trading contacts between Arabia and the East African coastline existed by the 1st century A.D., and there are indications of connections with India. The coastal trading centres were mainly Arab settlements, and relations between the Arabs and their African neighbours appear to have been fairly friendly. After the arrival of the Portuguese in the late 15th century, the position of the Arabs was gradually undermined, but the Portuguese made little attempt to penetrate into the interior. They lost their foothold north of the Ruvuma (Rovuma) River early in the 18th century as a result of an alliance between the coastal Arabs and the ruler of Muscat (on the Arabian Peninsula). This link remained extremely tenuous, however, until French interest in the slave trade from Kilwa revived the trade in 1776 and also aroused the sultan of Muscat's interest in the economic possibilities of the East African coast, where a new Omani governor was appointed at Kilwa. For some time most of the slaves came from the Kilwa hinterland, and until the 19th century such contacts as existed between the coast and the interior were due mainly to African caravans from the interior.

In their constant search for slaves, Arab traders began to penetrate farther into the interior, more particularly in the southeast toward Lake Nyasa. Farther north two Khojas (merchants) from Surat, in India, followed the tribal trade routes to reach the country of the Nyamwezi about 1825. Along this route ivory appears to have been as great an attraction as slaves, and after the transfer of his capital from Muscat to Zanzibar about 1830, Sultan Seyyid Said himself gave every encouragement to the Arabs to pursue these trading possibilities. From the Nyamwezi country the Arabs pressed on to Lake Tanganyika in the early 1840s and in the same decade reached the kingdom of Buganda, to the north of Lake Victoria. Tabora (or Kazé, as it was then called) and Ujiji, on Lake Tanganyika, became important trading centres, and a number of Arabs made their homes there. They did not annex these territories but occasionally ejected hostile chieftains. Manwa Sera, *mtemi* (ruler) of the Nyamwezi, was deposed in the late 1850s. Mirambo, an African chief who built for himself a temporary empire to the west of Tabora in the 1860s and 1870s, effectively blocked the Arab trade routes when they refused to pay him tribute. His empire was purely a personal one, however, and collapsed on his death in 1884.

The first Europeans to show an interest in Tanganyika in the 19th century were missionaries of the Church Missionary Society, J. L. Krapf and J. Rebmann, who in the late 1840s discovered Mt. Kilimanjaro. It was a fellow missionary, J. Erhardt, whose famous "slug" map (showing, on Arab information, a vast, shapeless, inland lake) helped stimulate the interest of the British explorers Richard (later Sir Richard) Burton and John Hanning Speke. They traveled from Bagamoyo to Lake Tanganyika in 1857–58, and Speke also saw Lake Victoria. This expedition was followed by Speke's second journey in 1860, in the company of J. A. Grant, to justify the former's claim that the Nile rose in Lake Victoria. These primarily geographical explorations were followed by the activities of David Livingstone, who in 1866 set out on his last journey for Lake Nyasa. Livingstone's object was to expose the horrors of the slave trade and, by opening up legitimate trade with the interior, to destroy the slave trade at its roots. Livingstone's journey led to the later expeditions of H. M. Stanley and V. L. Cameron, both of whom went in search of the famous explorer of whom there had been no news for some years. Stanley traveled as a newspaper reporter, while Cameron also had the additional objective of exploration. As these travelers followed the slave-trade routes, considerable areas of country remained unknown to Arabs and Europeans alike. Spurred on by Livingstone's work and example, a number of missionary societies began to take an interest in East Africa after 1860.

German Ascendancy.—The main threat to the Arab slave trade, however, came from a different quarter: Leopold II of Belgium formed the International Association for the Exploration and Civilization of Africa in 1876 to open up tropical Africa. After the failure of his East African expeditions he turned to the west coast. It was then left to Germany with its newly awakened interest in colonial expansion to open up the country to European influences. The first agent of German imperialism was Karl Peters, who, with Count Joachim Pfeil and Karl Juhlke, evaded the sultan of Zanzibar late in 1884 to land on the mainland. He made a number of "contracts" in the Usambara area by which several chiefs were said to have surrendered their territory to him. Peters' activities were confirmed by Bismarck, a convert to imperialism, who had paved the way for German intervention in Africa during the Berlin Conference (1884–85). By the Anglo-German Agreement of 1886 the sultan of Zanzibar's vaguely substantiated claims to dominion on the mainland were limited to a ten-mile-wide coastal strip, and Britain and Germany divided the hinterland between them as spheres of influence, Germany taking the region later known as Tanganyika. Following the example of the British to the north, the Germans obtained a lease of the coastal strip from the sultan in 1888, but their tactlessness, and fear of commercial competition, led to the outbreak of a Muslim rising in August 1888. The rebellion was put down only after the intervention of the Imperial German government and with the assistance of the British Navy.

Recognizing the administrative inability of the German East Africa Company, which had hitherto ruled the country, the German government declared a protectorate over its sphere of influence in 1891 and over the coastal strip where the company had bought out the sultan's rights. Germany was anxious to exploit the resources of its new dependency. Between 1894 and 1906 about £4,500,000 was voted by the German government to assist in the development of East Africa, while numerous private financiers invested substantial sums in the country. Lack of communications at first restricted development to the coastal area. The introduction of sisal from Florida in 1892 marked the beginning of the territory's most valuable industry, which was encouraged by the development of a railway from the new capital of Dar es Salaam to Lake Tanganyika. In 1896 work began on the construction of a railway running northwestward from Tanga to Moshi, which it reached in 1912. This successfully encouraged the pioneer coffee-growing activities on the slopes of Mt. Kilimanjaro. Wild rubber tapped by Africans, together with plantation-grown rubber, helped swell the country's economy. The government also supplied good-quality cotton seed free to African growers and also sold it cheaply to European planters. In 1902 the Amami Biological and Agricultural Institute was opened in the Usambara Mountains to investigate some of the scientific aspects of increased production. The administration also tried to make good the lack of clerks and minor craftsmen by encouraging the development of schools, an activity in which various missionary societies were already engaged.

The enforcement of German overlordship was strongly resisted, but control was established by the beginning of the 20th century. Almost at once, came a reaction to German methods of administration with the outbreak of the Maji Maji rising in 1905. This was a revolt against the manner in which the Germans ignored local traditions, employed forced labour, and compelled people to grow cotton. Although there was little organization behind it, the rising spread over a considerable portion of southeastern Tanganyika and was not finally suppressed until 1907. It led to a reappraisal of German policy in East Africa. The Imperial government had attempted to protect African land rights in 1895 but had failed in its objective in the Kilimanjaro area. Similarly, labour legislation of a liberal character had not been properly implemented. The German government set up a separate Colonial Department in 1907, and more money was invested in East Africa. A more liberal form of administration rapidly replaced the semimilitary system that had previously existed.

World War I put an end to all German experiments. Blockaded by the British Navy, the country could neither export produce nor get help from Germany. The British advance into German territory continued steadily from 1916 until the whole country was

eventually occupied. The effects of the war upon Germany's achievements in East Africa were disastrous; the administration and economy were completely disrupted. In these circumstances, the Africans reverted to their old social systems and their old form of subsistence farming. Under the Treaty of Versailles (1919) the U.K. received a League of Nations mandate to administer the territory except for Ruanda-Urundi, which came under Belgian administration, and the Kionga triangle, which went to Portugal.

British Mandate.—Sir Horace Byatt, administrator of the captured territory and, from 1920 to 1924, first British governor and commander in chief of Tanganyika (as it was then renamed), proposed a period of recuperation before new development schemes were set on foot. The handful of Europeans in the country resented his tardiness, but Byatt sheltered behind the fact that the terms of the League of Nations mandate under which Britain was to administer the former German East African dependency were not implemented until 1922. The first important result of the mandate was the Land Ordinance (1923), which ensured that African land rights were secure.

Sir Donald Cameron, who was governor from 1925 to 1931, infused new vigour into the country. He reorganized the system of native administration by the Native Authority Ordinance (1926) and the Native Courts Ordinance (1929). His object was to build up local government on the basis of traditional authorities, an aim that he pursued with doctrinaire enthusiasm and success. He attempted to silence the criticisms by Europeans that had been leveled against his predecessor by urging the creation of a Legislative Council in 1926 with a reasonable number of nonofficial members, both European and Asian. After an investigation of Tanganyika's labour problems, a Labour Department was also set up in 1926. In his campaign to develop the country's economy, Cameron won a victory over opposition from Kenya by gaining the British government's approval for an extension of the Central Railway Line from Tabora to Mwanza (1928). His attitude toward European settlers was dependent upon their potential contribution to the country's economy. He was, therefore, surprised by the British government's reluctance to permit settlement in Tanganyika. Over the issue of closer union with the other East African territories, he stood in even stronger opposition to the British government, since he regarded the suggestion as being detrimental to the growth of his own system of native administration. His opposition played an important part in defeating the proposal. The economic depression after 1929 resulted in the curtailment of many of Cameron's development proposals; the Labour Department was abolished, and money for education was restricted. In the 1930s, too, Tanganyika was hampered by fears that it might be handed back to Germany in response to Hitler's demands for overseas possessions.

At the outbreak of World War II Tanganyika's main task was to make itself as independent as possible of imported goods. Inevitably the retrenchment evident in the 1930s became still more severe, and, while prices for primary products soared, the value of money depreciated proportionately. Tanganyika's main objective after the war was to ensure that its program for economic recovery and development should go ahead. The continuing demand for primary produce strengthened the country's financial position. The chief item in the country's development program was a scheme to devote 3,000,000 ac. (1,200,000 ha.) of land to the production of peanuts by the most modern agricultural methods. The scheme, which was to be financed by the British government, was to cost £25,000,000, and, in addition, a further £4,500,000 would be required for the construction of a railway in southern Tanganyika. It failed because of the lack of adequate preliminary investigations and was subsequently carried out on a greatly reduced scale.

Constitutional Progress and Independence.—Constitutionally, the most important immediate postwar development was the British government's decision to place Tanganyika under UN trusteeship in 1947. Under the terms of the trusteeship agreement, Britain was called upon to develop the political life of the territory, which, however, only gradually began to take shape in the 1950s with the growth of the Tanganyika African National Union (TANU). The first two African members had been nominated to the Legislative Council in December 1945. This number was subsequently increased to four, while there were three Asian nonofficial members and four Europeans. An official majority was retained. There was an important advance in 1955 when the three races were given parity of representation on the unofficial side of the council with ten nominated members each, and for a time it seemed as if this basis would persist. The first elections to the unofficial side of the council, however, enabled TANU to show its strength, for even among the European and Asian candidates only those supported by TANU were elected. A constitutional committee in 1959 unanimously recommended that after the elections, in 1960, a large majority of the members of both sides of the council should be Africans and that elected members should form the basis of the government. The approval of the colonial secretary was obtained for these proposals in December 1959, and in September 1960 a predominantly TANU government took office. The emergence of this party and its triumph over the political apathy of the people were largely due to the leadership of Julius Nyerere, and his success gave the lie to those who had insisted that British concentration on the development of local government on a traditional basis had acted as a barrier to the emergence of a unified state. Tanganyika became independent in December 1961, with Nyerere as its first prime minister. The November 1962 elections for the country's first president under a republican constitution resulted in an overwhelming victory for Nyerere. On Dec. 9, 1962, the anniversary of its independence, Tanganyika became a republic within the Commonwealth.

In April 1964 the presidents of Tanganyika and Zanzibar signed an act of union of their two countries, which would thenceforth be known as the United Republic of Tanzania. Nyerere was appointed the first president of the new republic, with Abeid Amani Karume of Zanzibar as first vice-president. (K. I.)

ADMINISTRATION AND SOCIAL CONDITIONS

Constitution and Government.—Under the 1962 constitution Tanganyika became a republic within the Commonwealth of Nations, with an executive president, who is both head of state and head of government. The first president was elected directly under a system of universal suffrage, but in the future the election of the president was to be directly linked with the election of the members of parliament (the National Assembly), to ensure that the presidency would, as far as possible, be closely associated with the majority party in the National Assembly. A presidential election is held whenever parliament is dissolved. The assembly consists of 71 elected members and up to 10 members nominated by the president, who has no power to legislate without recourse to parliament. His assent, however, is required before any bill passed by the assembly can become law. If he withholds his assent and the bill is again passed by the assembly by a two-thirds majority, he is required by law to give his assent within 21 days, unless, before that time, he has dissolved the assembly. To assist him in carrying out his duties he is empowered to appoint a vice-president (who must be an elected member of the assembly), who is leader of government business in parliament. The vice-president and other ministers comprise the Cabinet, which is presided over by the president. He is not bound to act on the Cabinet's advice. After the union of Tanganyika with Zanzibar in April 1964, the new state was to be governed in accordance with the constitution of Tanganyika until a new constitution had been approved.

Local Government.—For the purposes of local government the country is divided into 17 regions (*see* table); these are subdivided into districts under district commissioners responsible to the regional commissioners. Local government is concerned with such matters as primary education, agriculture, marketing, forestry, and health.

Common Services.—Tanganyika is a member of the East African Common Services Organization (which replaced the East African High Commission), an interterritorial body administering certain services common to Kenya, Uganda, and Tanganyika (tariffs and customs, railways, harbour services, postal services and telecom-

munications, civil aviation, commercial and industrial co-ordination). Policy decisions (which must be unanimous) of the common services authority are reached in concert by the heads of government of the three countries; the various services are dealt with similarly by a triumvirate of ministers.

Living Conditions.—The cost of living increased by more than 40% in the decade following 1950. The customs and outlook of the people vary greatly in different areas, but generally standards of living are higher in zones where cash-crop cultivation supplements subsistence agriculture. The reported number of persons in paid employment in the mid-1960s was more than 400,000. The average per capita income in the same period was about £24 ($67) annually. There were more than 40 trade unions, with an estimated membership of more than 65,000. The increase in the population of urban areas after World War II caused a housing shortage, and in the early 1950s the government began a low-cost housing program.

Health and Welfare.—In the mid-1960s the government, missions, and local authorities maintained more than 800 maternity and child-health clinics, about 250 hospitals with 15,000 beds, about 20 major leprosariums, and more than 1,000 out-patient dispensaries. Expenditure on medical and allied services (including public-health measures by local authorities) amounted to more than £2,000,000 annually. The most prevalent diseases included malaria, sleeping sickness, smallpox, and leprosy.

Justice.—There is a High Court with final jurisdiction in both criminal and civil cases, composed of a chief justice appointed by the president and of lesser judges appointed by the president after consultation with the chief justice. Subordinate courts have limited jurisdiction in each district.

Education.—Schooling in Tanganyika was pioneered by the missions and supplemented by the central government and local authorities. The schools (primary, middle, and secondary) were developed on a racial basis but were integrated from 1961. By the mid-1960s about 500,000 children (or about half of those of school age) entered primary schools, and a large proportion of these left after the four-year primary course, while after the four-year middle-school course about 20,000 pupils proceeded to secondary schools. Swahili is the language of instruction in primary schools, though English is introduced in the third year and becomes the medium in middle schools. School broadcasting is used to supplement formal work and to provide a common cultural background. In the mid-1960s it was planned to increase the primary-school course to eight years, abolish the middle schools, and expand secondary education. Trade schools include large residential establishments (mainly for building and engineering) at Ifunda and Moshi; there is a well-equipped technical institute at Dar es Salaam. The University College, also at Dar es Salaam, has faculties of law and arts. In the mid-1960s many Tanganyikans were pursuing studies abroad; these included students attending Makerere University College, Kampala, Uganda, and the University College, Nairobi, Kenya. About 2,000 teachers were being trained annually at more than 20 training centres, including a college at Changombe. Current expenditure by the government on education rose from just under £300,000 in 1947 to more than £4,000,000 in the mid-1960s (more than one-tenth of total government current expenditure).

Defense.—Tanganyika's forces comprise the two battalions of the Tanganyika Rifles, which before independence were attached to the King's African Rifles. (J. P. Mt.; X.)

THE ECONOMY

Agriculture dominates the economy, accounting for about 80% of the exports by value. There is an important livestock industry, and mining production is considerable.

Agriculture and Forestry.—Sisal is the most important product. Plants of *Agave sisalana* were introduced from Florida in 1892 by the German agronomist Richard Hindorff. By 1914 production reached 20,000 tons of fibre annually and by the 1960s usually exceeded 200,000 tons, making Tanganyika the leading world producer. Coffee, tea, pyrethrum, and tobacco are grown in the upland areas, grains (maize [corn], millet, sorghum, rice), cotton, cocoa, pulses, peanuts, and oilseeds in the higher rainfall areas of the plains, and coconuts, cassava, cashew nuts, and citrus fruits in the coastal belt. The principal subsistence crops are sugar, maize, millet, cassava, bananas, and pulses. In the 1960s irrigation projects were developed in central Tanganyika and in the Rufiji and Mbarali river basins. In the drier plains pastoral tribes herd cattle, sheep, and goats, but tsetse infestation hinders the livestock industry. Areas of true forest are limited, but valuable timbers include muninga, camphor, muvule, and African mahoganies and blackwood. The co-operative movement is widespread, and the value of produce handled is about 25% of the total value of exports.

Mining.—Diamonds account for about two-thirds by value of Tanganyika's mineral output. Diamondiferous deposits around Shinyanga, south of Lake Victoria, were discovered in 1940 by J. T. Williamson, and by the mid-1960s the mine at Mwadui (in which the government acquired a half share) was producing more than 600,000 k. annually. Gold (about £1,200,000 annually), salt, silver, mica, and tin are among mining products. Immense deposits of iron ore and coal exist in the southwest near Lake Nyasa but are difficult of access.

Power and Industries.—Electric power generation and supply are carried out by a company with an exclusive franchise. Thermal power stations exist at Dar es Salaam, Lindi, Mtwara, Iringa, Mbeya, Dodoma, Tabora, Kigoma, Morogoro, Mwanza, Arusha, and Moshi. Major hydroelectric installations include one at Pangani Falls (17.5 megawatts) and the Hale Station on the Pangani River (21.5 megawatts), completed in 1964, with a transmission line to serve Dar es Salaam and the adjacent area along the Central Railway Line.

Manufacturing industries are mostly connected with agricultural and forest products (food, flour and sisal processing, oil, and sawmilling) but include the production of textiles, clothing, cans, paint, and soap for local consumption, as well as soft drinks, beer, cigarettes, aluminum ware, bricks and tiles, coir and sisal matting, leather, cement, industrial gases, and shoes. By the early 1960s manufacturing contributed about 4% of the gross domestic product.

Trade.—About 50% of Tanganyika's gross domestic product derives from agriculture, and the economy is therefore sensitive to changes in the prices of export products, notably sisal, which fell from £100 per ton in 1950 to under £70 a ton in the early 1960s. Total exports (including those to Kenya and Uganda and re-exports) averaged about £55,000,000 annually, about one-third being taken by the U.K. and about one-fifth by other Commonwealth countries. Exports in order of value were sisal, cotton, coffee, diamonds, oilseeds and nuts, hides and skins, canned meat and meat extracts, gold, tea, beans and pulses, and tobacco. Imports (mainly textiles, vehicles and transport equipment, petroleum fuels, iron and steel, machinery, chemicals, and foodstuffs) included substantial quantities of local produce from Kenya and Uganda and totaled about £40,000,000 annually, more than one-third coming from the U.K.

Finance.—Most of Tanganyika's recurrent revenue is derived from direct sources (income and personal taxes, local government rates, company taxes, etc.) and indirect (customs and excise duties and income from government properties). Among the main items of expenditure are education, communications, power, public works, police, agriculture, health, and labour. The currency is identical with that of Kenya, being based on the East African shilling, which is legal tender for any amount and is subdivided into 100 cents. Other coins are of 1, 5, 10, and 50 cents; notes are issued of EAShs. 5, 10, 20, 100, and 1,000. EAShs. 20 = EA£1, the latter being at par with the U.K. pound sterling. Commercial banks with branches in Tanganyika include three British, two Indian, one South African, one Dutch, and one Turkish. The East African Currency Board, with headquarters at Nairobi, controls the issue and supply of currency. An ambitious development plan covering the period up to 1970, and involving the expenditure of £246,000,000, was announced in 1964.

Transport and Communications.—The railways form part of the East African Railways and Harbours System. There are

three main lines, all of metre gauge: the central line from Dar es Salaam to Kigoma (779 mi. [1,254 km.]), with branches to Mwanza on Lake Victoria from Tabora (236 mi. [380 km.]), to Mpanda from Kaliua (131 mi. [211 km.]), and to Mikumi southward from Kilosa (44 mi. [71 km.]); Tanga to Arusha (272 mi. [438 km.]), with a link eastward from Kahe to Voi (94 mi. [151 km.]) on the Mombasa-Nairobi line in Kenya and a link southward from Mnyusi to Ruvu (117 mi. [188 km.]) on the central line; and Mtwara to Masasi (154 mi. [248 km.]). Diesel traction is used.

Tanganyika has about 700 mi. (1,100 km.) of roads in towns and settlements, 3,800 mi. (6,100 km.) of territorial roads, 5,800 mi. (9,300 km.) of local roads, 10,800 mi. (17,400 km.) of district roads (usually metaled), and 8,500 mi. (13,700 km.) of village roads. The East African Railways and Harbours Administration operates passenger and freight road services, and there are widespread local bus and truck services. More than 20 shipping lines operate services to Tanganyika, some calling at Tanga and Mtwara, as well as at Dar es Salaam. There are passenger and cargo services on Lakes Victoria, Tanganyika, and Nyasa. East African Airways Corporation operates internal scheduled flights and services to the U.K., South Africa, India, and Pakistan; other airlines maintain links with adjoining territories. There is the usual range of postal services but no house-to-house delivery by postmen, the box or private bag system being used. Scheduled air services are widely used for mail transport. About half the telephone exchanges are automatic; landline and radiotelegraph services are provided, and an overseas radiotelephone service. Radio broadcasting is controlled by a corporation directed by a government-nominated board and emanates from Dar es Salaam, with a national program in Swahili and a second program in English and Asian languages.

Current history and statistics are summarized annually in *Britannica Book of the Year*.

TANGANYIKA, LAKE, in East Africa, is the longest freshwater lake in the world (420 mi.) and the second deepest (4,708 ft.) but is comparatively narrow, varying in width from 30 to 45 mi. It covers about 12,700 sq.mi. and forms the boundary between Tanganyika and the Republic of the Congo. It occupies the southern end of the western arm of the Great Rift Valley, and for most of its length the land rises steeply from its shores. Its waters are drinkable but slightly brackish.

The lake was first visited in 1858 by R. F. Burton and J. H. Speke, who reached Ujiji, the place where in 1871 H. M. Stanley "found" David Livingstone. The southern half was first circumnavigated by V. L. Cameron in 1874, when the Lukuga outlet was discovered, and the whole lake was surveyed by Stanley in 1876.

The lake is fed by a number of rivers but is not the centre of an extensive drainage area. The largest river is the Malagarasi, which rises to the north of Kigoma. Others are the Russisi (Ruzizi), which carries the overflow from Lake Kivu, and the Kalambo, on which is situated one of the highest waterfalls in the world (over 700 ft.).

The lake is situated on the dividing line between the floral regions of east and west Africa, and the oil-palm, so characteristic of the latter, is found on its shores. Rice is grown in suitable areas on the lake littoral. An agreement was being negotiated in 1953 with the Belgian authorities to stabilize the level of the lake. Fishing for *dagaa*, a small fish not unlike whitebait, is carried on by African fishermen in dug-out canoes at night by the light of flares, and dried fish valued at over £125,000 was exported to the Congo in 1951.

Hippopotami and crocodiles abound in the waters of the lake, and in places the rare west African sharp-snouted crocodile, *crocodilus cataphractus*, occurs. The bird life is most varied, because of the lake's situation between the east and west African regions. The mountains north and south of Kigoma are the only places in Tanganyika where the chimpanzee is to be found.

There had been considerable traffic across the lake before the arrival of the European, but this had nearly all been from west to east, so that many of the numerous tribes now living on its eastern borders trace their origins to areas in the Congo. They are predominantly Bantu, with traces of Hamitic (Tusi) influence in the north and of Zulu (Angoni) in the south. The areas of both sides of the lake suffered heavily in the past from the depredations of slave traders.

The chief towns on the lake are Usumbura, Uvira, Albertville, Kigoma, Ujiji, Karema, Mtakuja, Kipili, Mpulungu, Kasanga and Moliro. Steamers ply on the lake, traversing its length in about four days. Communications across the lake are from Kigoma, the terminus of the railway line from Dar es Salaam, to Albertville, whence there is a rail link to the Lualaba river.

Bibliography.—Accounts of the discovery and early exploration of Lake Tanganyika are to be found in the works of such explorers as Sir R. F. Burton, David Livingstone, V. L. Cameron, H. M. Stanley, E. C. Hore and J. Thomson. *See* also H. Meyer, *Das Deutsche Kolonialreich* (1909–10); H. Schnee (ed.), *Deutsches Kolonial Lexikon* (1920); *Tanganyika Notes and Records* (issued twice yearly, Dar es Salaam, 1936 *et seq.*). (J. P. Mt.)

TANGERINE, a small thin-skinned variety of orange belonging to mandarin orange species (*Citrus reticulata*). The principal distinguishing characteristic of the tangerine in comparison with the rest of the mandarin species is deeper reddish-orange colour of the peel of the tangerine. *See* Orange.

TANGIER (locally Tanja) is a seaport of Morocco, on the Strait of Gibraltar, about 7 mi. E. of Cape Spartel, between two eminences at the northwest extremity of a spacious bay.

As seen from the sea, the town rises gradually in the form of an amphitheatre, with the citadel, the remainder of the English mole and York castle to the right; the commercial quarter in the central valley; and the road to Tetuan running along the beach to the left. The main thoroughfare leads from Bab el Marsa (Gate of the Port) to the Bab el Suk (Gate of the Market place) known to the English as Catherine Gate. European quarters have also been built to the north of Tangier (the Marchan quarter), to the west (on the "Mountain") and to the south (quarter of the beach and of Suani). The harbour, formed by the Bay of Tangier, is good in all weather except during a strong east wind, but large vessels have to anchor about a mile out. A deep-water harbour was begun in 1925. The population of the former international zone was 79,886 in 1940, of which 50,250 were Moslems, 7,102 Jews, 15,486 Spanish, 1,642 French, 1,389 English and 4,017 others; in 1954 the total was estimated as 175,000, including 15,000 Moroccan Jews and 42,000 Europeans (35,000 Spaniards, 8,000 French, 1,000 others). Area of the former international zone of Tangier was 135 sq.mi. Pop. of the city (1960) is 141,714.

History.—The ancient Tingis stood very near the modern site of Tangier. Under Augustus it became a free city of the Roman empire; and when Otho placed the western half of Mauretania under a procurator, he called it Mauretania Tingitana. It was held successively by Vandals, Byzantines and Arabs; and when Mulai Idris passed from Tlemçen to Fez in 788, Tangier was "the oldest and most beautiful city" of the Maghrib. After many futile attempts the Portuguese obtained possession of it in 1471; it passed with Portugal to Spain in 1580, returning to the independent Portuguese in 1656.

In 1662, as part of the dowry of Catherine of Braganza on her

marriage to Charles II, it came into the possession of the English, who defended it against Mulai Ismail in 1680 but in 1684 decided, on account of expense, to abandon it to the Moors. The sultans made Tangier the seat of foreign representation, to keep Fez free from extraneous influences; and capitulatory rights were granted to western nations (1630–1880) as well as certain powers of sanitary control. (A. BE.; X.)

A special regime for Tangier, growing out of the interest of Great Britain in the Strait of Gibraltar, was envisaged in the Moroccan arrangement of 1904 between Britain and France on the one hand and France and Spain on the other; and in the Algeciras act (1906) Tangier's international character was fully recognized. The principle was reiterated in the protectorate convention of 1912 and in the Franco-Spanish convention of the same year.

In 1913 Great Britain, France and Spain began negotiations to create a "Tangier zone" with an international regime. When, however, World War I broke out Spain withdrew, apparently in the hope of acquiring Tangier for itself.

The Statute of 1923.—It was not until 1923 that Tangier's status was at last regulated. Though France's position in Morocco had become stronger, Britain was still determined on an international form of government; and Spain supported this demand.

Negotiations culminated in the statute of Tangier, which remained in force down to 1940. It was signed by Britain and France in 1923 and by Spain in 1924. All states signatory to the Algeciras act (except the Central Powers and Russia) were immediately invited to adhere to it; and all did so except Italy and the U.S. Its main provisions were as follows:

1. The Tangier zone was to be permanently neutralized, though troops proceeding to or from the French or Spanish zone of Morocco might cross the territory after notification to the administrator. A police force, not exceeding 250 Moroccans, under a Belgian officer with French and Spanish subordinates, was to be at the disposal of the administrator.

2. Native administration and control over all Moslem institutions was to be entrusted to a mendub representing the sultan.

3. A legislative assembly of 26 members was to be instituted consisting of 17 Europeans (four French, four Spanish, three British, two Italian, one American, one Belgian, one Dutch and one Portuguese, nominated by their respective consuls) and 6 Moslem and 3 Jewish subjects of the sultan (nominated by the mendub). The mendub was to preside over the assembly.

4. A committee of control, composed of the consuls of powers signatory to the Algeciras act (former enemy countries excluded), was given a power of veto over the enactments of the legislature and charged with ensuring observance of the statute.

5. An administrator-general, head of the executive, and two assistant administrators for health and finance, were to be appointed for an initial period of six years by the sultan at the instance of the committee of control; these were to be of French, Spanish and British nationality. Appointments after this were to be assigned by the assembly to nationals of signatories of the Algeciras act.

6. An international mixed court was to administer justice in all matters affecting foreigners. It was to consist of one French, one Spanish, and two British judges, with a Frenchman and a Spaniard as public prosecutors for criminal and civil matters.

7. A port commission was also established, consisting of one member of the sultan's government, one of the legislative assembly, one of the committee of control.

France secured preponderance in the administration, helped by the fact that as the international zone was a concession from the Moroccan government, itself under French protection; Spain was allotted a secondary role. The interests of Tangier itself were in the main disregarded. An Italian request for participation and Spanish dissatisfaction with the working of the whole system led to the revision of the statute in 1928. Italy acquired a share in the administration roughly equivalent to Britain's. Spain secured a more effective suppression of arms smuggling and of political disturbances. But Spain, still aspiring to incorporate Tangier in its zone, subsequently demanded joint control with France over the native Moslem and Jewish population; for a rotation of Frenchmen and Spaniards as chief administrators; and for posts in the customs. These demands were not favourably received.

Spanish Occupation, 1940–45.—After the collapse of France and Italy's entry into World War II, Spanish troops occupied Tangier on June 14, 1940; and in Nov. 1940 the Spanish authorities incorporated it into the Spanish zone of Morocco.

Early in 1941 Britain concluded an interim agreement with Spain, which, without prejudice to British and third-party rights under the international statute, guaranteed free entrance into and departure from Tangier to British subjects and the continued functioning of British enterprises in the zone. Spain also formally undertook to keep the zone demilitarized.

Postwar Regime, 1945–56.—In August 1945 a conference on Tangier was held at Paris by representatives of Britain, France, the United States and the U.S.S.R. It was found impossible to draw up a new international statute since the U.S.S.R. refused to co-operate with General Franco's Spain; Britain, France and the United States, on the other hand, held that Spanish interests could not be ignored. Finally a compromise was reached: if Spain withdrew its troops at the request of the four powers, a provisional regime, based on the statute of 1923, as modified in 1928, was to be set up for six months; Spain was to be allowed to participate in this regime by having a Spanish consul on the control committee and a Spaniard sitting in the legislative assembly; the United States and the U.S.S.R. were to be invited to collaborate; and after six months had elapsed a new conference was to be held, to which all powers signatory to the Algeciras act (excluding former enemy countries) and the U.S.S.R. were to be invited, to draw up a permanent international statute for Tangier. Spain accepted the decision of the Paris conference; and the provisional regime came into force in Oct. 1945.

Under the Paris agreement it had been decided that the principal interested powers, France, Spain, and Britain, should no longer hold any of the most important posts in the administration; these were to be left to smaller powers. Britain renounced its former preponderant share in the administration of justice. Spain retained only its membership of the control committee and the legislative assembly. France renounced the right to have a Frenchman as administrator general but managed to insert clauses in the agreement which stipulated not only that a Frenchman should remain as second in command of the police but also that a new post, that of assistant administrator of Moroccan affairs, should be created for a Frenchman. Moreover, before anyone else had arrived, the French succeeded in recruiting enough officials to staff the administration and all the necessary police; and also, as under the statute of 1923, they continued to nominate the Moroccan members of the legislative assembly, while Moroccan interests in the control committee were represented only by a French consul general.

France thus retained a preponderant share in the administration, though the influence of the United States, preserving its capitulations there as elsewhere in Morocco, made itself increasingly felt. After six months no new conference on Tangier was called, and the provisional administration was maintained.

A new factor in the situation after World War II was the growing dissatisfaction of the Moroccans with their subordinate position. Though they had nine representatives in the legislative assembly they had no representative on the control commission, which could veto the decisions of the assembly. Italy was readmitted to the committee of control in March 1948, after signing a peace treaty with the Allies, on the invitation of France and Britain with the concurrence of all the signatories to the Algeciras act (except those excluded in 1919) and the U.S.S.R.

On March 30, 1952, the 40th anniversary of the Fez treaty which had imposed the French and Spanish protectorates on Morocco, a violent riot of the Moroccan Nationalist party took the international authorities by surprise. In June it was decided to create a motorized public corps with a Spaniard as its commander and a Frenchman as his deputy.

International Zone Abolished.—As a consequence of the recognition of Morocco's independence and sovereignty by France (March 2, 1956) and by Spain (April 7, 1956), the statute of Tangier was abolished on Oct. 29, 1956, with the signature of an

eight-power declaration and a protocol, the last-named signed also by Ahmed Balafrej, the Moroccan foreign minister.

Haj Mohammed el-Tazi, the mendub, resigned on July 8, 1956, and a governor was appointed by the king of Morocco.

On Aug. 29, 1957, a royal charter was granted to Tangier confirming the maintenance of freedom of exchanges and of foreign trade and introducing a moderate fiscal system. *See* also Morocco. (S. E. Ce.)

TANGO, a ballroom dance of Spanish American origin, popular in the Americas and Europe since about 1915. The tango is danced to music similar in rhythm to that of the Cuban habanera, though faster, and played in 4–4 time. The basic step patterns take two measures, counted slow, slow, quick, quick, quick, hold. (A. Mu.)

TANGUAY, EVA (1878–1947), U.S. vaudeville and musical comedy star, was born in Marbleton, Que., and went to the U.S. with her parents at an early age. She obtained her first footlight role at the age of eight in *Little Lord Fauntleroy* and later acted in variety, stock troupes and musical comedies. By the age of 20 she was regarded as an accomplished comedienne. At the turn of the century, Miss Tanguay shocked audiences with her daring costume—or lack of costume—and her risqué songs, and by 1910 she was an established and popular star of the theatre. Her earnings were phenomenal but she lost her fortune during the stock market crash of 1929. Her health and vision soon failed, bringing her career to an abrupt end. She spent the last two decades of her life a virtual recluse, bedridden and mostly forgotten. She died in Hollywood, Calif., on Jan. 11, 1947.

TANIMBAR ISLANDS (Timorlaut Islands), a group of islands in the Malay archipelago, southwest of the Aru Islands, between 6° 20′ and 8° 30′ S., and 130° 40′ and 132° 5′ E. Politically the islands belong to Indonesia. They form part of the outermost alpine arc which includes Timor and the Ewab Islands and recurves westward through Ceram and Buru. The group lies outside the zone of recent volcanic activity. There are about 30 islands, the largest being Jamdena (70 mi. long by 28 mi. wide). Thickly wooded hills extend along the east coast; the west coast is lower, where, opposite the island of Sera, a gulf extends far inland. In places there are precipitous cliffs, and a narrow foreshore is fringed with coconut palms and mangrove. There are many small islands off the western coast of Jamdena; off the northeastern coast is Larat (20 mi. long by 5 mi. wide), with a rocky coast and high cliffs, and with thick vegetation along the foreshore; and off the southwestern coast, Selaru, which is 32 mi. long, rather flat, and with much grassland.

There are extensive swamps on many of the islands and fever is prevalent during the southeast monsoon. The soil supports maize, rice (in small stretches), coconut and sago palms, yams, plantains, mangoes and papayas. There are practically no rivers and there is a lack of fresh water. The slight depth of soil prevents trees from attaining great height.

The vegetation includes sterculias and fig trees, leguminous trees and shrubs, myrtles, the scarlet hibiscus, pandanus, palms, a species of breadfruit tree, rare and lovely orchids of many kinds, crotons, dracaenas and many varieties of ferns. The animal life shows Australian affinities and comprises wild buffalo, wild pig, the cuscus, flying fox, many snakes, lizards and frogs. The birds include the scarlet lory, honey eater, ground thrush and oriole. Butterflies are numerous and include *Papilio aberram,* and among the beetles is a gorgeous golden-coloured buprestid (*Cyphogastra splendens*).

The islands, with two divisions, Larat and Saumlaki, are included in the province of the Moluccas. The capital of Jamdena is Saumlaki, at the southwestern end of the island, and of Larat, the town of the same name, on a narrow strait opposite Jamdena.

The isles were first visited by Capt. Owen Stanley, in 1839, and became known to Banda traders in 1877. In 1878 H. O. Forbes, with his wife, visited the islands and stayed there three months, being warned before going by the Dutch authorities of the hostility and savagery of the inhabitants; he appears to have been the first European who stayed any length of time. After his visit the islands were opened up by the Dutch, and the islanders proved responsive to outside civilizing influences.

The population (1930 census) was 31,847. The people are undoubtedly a mixed group. Some of the men are tall, others are short and thickset, the complexion of nearly all being a rich chocolate brown. The basic stock is Oceanic negroid of the Papuan variety, but there has been much mixture with mongoloid strains, first of the Indonesian type and later, especially around the coast, with Malays.

There are many pagans and a few Moslems. Christianity made some headway, and under Dutch rule cannibalism, piracy, slavery, head-hunting and intertribal fighting were suppressed. The men sometimes dye their hair a golden colour. Tattooing is known. Traces of totemism and of an age-group system survive. Their houses of wood and *atap,* sometimes built in closely packed settlements, generally on piles and entered from underneath, have carved pillars and show much artistry of construction. The men are skillful boatbuilders, use the spear and bow and arrow (with which they are adept in shooting fish), hunt, search for trepang and turtle shell, are agriculturists, keep pigs and work in iron, copper and gold. The women cultivate the fields after the men have prepared the ground, weave and dye sarongs and plait.

(E. E. L.; B. A. L. C.; T. Her.)

TANJORE, a city, with *tehsil,* and an eastern coastal district in Madras state, India. The city is on the right bank of the river Cauvery, and is an important junction on the Southern railway, 218 mi. S. of Madras. Pop. (1951): city 100,680; taluka (421 sq.mi.) 381,984. It was the last capital of the ancient dynasty of the Cholas (*q.v.*). It was the scene of the earliest labours of Protestant missionaries in India. The modern history of Tanjore begins with its conquest by the Marathas in 1674. The British first came into contact with Tanjore by an abortive expedition in 1749 to restore a deposed raja. The Marathas practically held Tanjore until 1799, when the district was ceded to the East India company. The raja retained only the capital and a small tract of country round. He died in 1833 and was succeeded by his son Sivaji, on whose death in 1855 without an heir the house became extinct. Among buildings may be mentioned the palace within the fort, and the richly ornamented temples of Rajrajeswara (*c.* A.D. 1000) and Subrahmaniya (built in the compound of the former).

The city is famous for its silk brocade, jewelry, carpets, inlaid copperwork, modeling in pith, etc.

Tanjore District has an area of 3,740 sq.mi. It is irrigated by an elaborate system of dams, cuts and canals and is exceedingly productive. The delta of the Cauvery occupies the flat northern part, which is highly cultivated, dotted over with groves of coconut trees and densely populated. The staple crop is rice, grown on about five-sevenths of the cultivated area, and rice milling has also developed. Soap and mats are made and fishing carried on. The chief seaport is Negapattinam (57,854). Other important places are Kumbakonam (91,643), also a former Chola capital, a pilgrimage place, and a manufacturing centre for metalwork, silk, cotton and sugar; and Mayuram (43,436), with an ancient temple.

The 1951 district population was 2,982,670.

TANK. A self-propelled combat vehicle embodying the military characteristics of fire power, mobility and crew protection. Tanks may be used as part of larger infantry units, as a separate striking force or for reconnaissance.

PREDECESSORS

The modern military tank is a direct outgrowth of World War I, but the idea underlying its development—protected, mobile striking power—had been used throughout the history of warfare. Many ancient peoples made use of war chariots to carry an attack to an enemy with speed and with some degree of protection. The armoured elephants of Hannibal and Kublai Khan were variations of the same idea. In the 15th century Leonardo da Vinci envisioned his covered chariots as a means of destroying the artillery just then being introduced to warfare. From time to time similar suggestions were advanced and occasionally devices of this kind were used in war. However, there is no evidence that such great

military leaders as Condé, Turenne, Frederick the Great or Napoleon made any effort to revive the idea.

The invention of the "footed wheel" by R. L. Edgeworth in 1770 led to Thomas German's invention in 1801 of the jointed track. Neither of these was of any significance until the steam engine was applied to vehicles. However, Gottlieb Daimler's patent in 1886 of the high-speed internal-combustion engine opened the way for the first really practical self-propelled fighting vehicles. While interest in track-laying vehicles and improvements in their design continued in Britain and the United States during this period, the perfection of a reasonably efficient internal-combustion engine stimulated experiments in both these countries and in Europe, with various types of armoured cars. F. R. Simms of Britain is credited with building in 1898 the first motor vehicle designed for combat purposes; it was a light four-wheeled motorcycle with an armoured shield and mounting a Maxim machine gun.

In the same year a U.S. army officer, R. P. Davidson, designed a three-wheeled automobile similarly armed and armoured. Davidson experimented also with steam-driven combat cars, as did the Russian engineer Lutski. Davidson's cars were followed in rapid succession by the Charron car in France in 1901 and the Simms war cars in Great Britain in 1902. The first turreted armoured cars were built by the firm of Charron, Girardot et Voight in France in 1904 and purchased by Russia. These were followed by the Austro-Daimler cars in Austria-Hungary, which were the first four-wheel-drive automobiles. Several other British, French, Swiss and German cars appeared. Among them was the Armstrongs-Whitworth car designed by Walter G. Wilson, who later was prominent in design and production of British tanks during World War I. During this period the track-laying vehicle, as developed by Benjamin Holt, C. L. Best and others, was making great strides agriculturally in the United States.

During the years immediately prior to World War I, tacticians of the major powers which were to engage in that struggle did not seem to envision the part such a combat vehicle could play. Lieut. Fleicz of the French army and Capt. (later Gen.) J. F. C. Fuller (*q.v.*) of the British army, as late as 1913 and 1914, respectively, predicted the machine gun would bring about static trench warfare, and suggested greater emphasis on means for overcoming it. But it was not until the soundness of their ideas was clearly demonstrated along the Aisne in 1914 that serious attention was given to armoured, trench-spanning vehicles.

WORLD WAR I TANKS

The French and Belgians were quick to improvise armoured cars for fighting delaying actions against German advance cavalry. The tactics were informal but aggressive and usually whatever the individual car commander decided. When the war stabilized on the western front in 1914, Winston Churchill, then first lord of the admiralty, authorized the stationing of a large naval air force at Calais with temporary bases as far inland as possible. Churchill quickly saw the natural affinity between aircraft and armoured vehicles. As a result, the royal naval air service under Capt. Murray Sueter improvised armoured car squadrons for protecting advanced air bases and to rescue pilots who crashed or were forced to bail out in enemy territory.

When the war had settled down to a practically continuous front, it was because artillery and the machine gun dominated the battlefield. (*See* TACTICS and WORLD WAR I.) There were no flanks. With position defense and frontal attacks the only basic tactics available to either side, defense became superior to offense. Even when salients developed which permitted a form of envelopment, the attacker's own flanks became exposed and attacks eventually ground to a standstill, with casualties reaching staggering proportions. The tremendous artillery fire preparation frequently destroyed the attacker's ability to sustain his own advance because his artillery could not be displaced forward over the ground it had helped to make impassable.

British Tanks.—In Oct. 1914, Col. (later Gen.) Sir Ernest Swinton, having seen some American Holt caterpillar tractors used as heavy artillery tractors behind the lines, was struck with the desirability of arming and armouring such vehicles as an antidote to the German machine gun. He suggested the idea to the authorities but Churchill was the only member of the committee of imperial defense who was in favour of exploring it. At the end of Feb. 1915 the war office officially abandoned the Swinton proposals but Churchill immediately created a Landships committee under the chairmanship of Eustace (later Sir Eustace) Tennyson-d'Eyncourt, a prominent naval designer.

As a result of admiralty rather than war office sponsorship, certain naval terms came into use and persisted. Parts of armoured vehicles are still known by such naval terms as hull, turret, deck, sponson, barbette, superstructure, bow, hatch and compartment.

Various experimental machines were built, ending with a large vehicle having overhead tracks, mainly the product of W. G. Wilson and Sir William Tritton. Colonel Swinton learned of these and was authorized by the commander of the British forces in France to collaborate through the war office. In June 1915 the admiralty and war office joined hands. The abortive Dardanelles landing forced Churchill's resignation in July but the committee and Capt. Murray (later Admiral Sir Murray) Sueter of the Royal Navy kept interest alive in spite of army apathy. In September, primary responsibility was turned over to the war office but the Landships committee continued to function with little change except in name.

The word "tank" was coined by Swinton. Originally, for secrecy, the hull and chassis of an experimental vehicle had been made in different shops. The hull was referred to as a water carrier for Mesopotamia and was called "that tank thing" by the workmen. The chassis was described as a demonstrational chassis for the royal marines. Swinton later recalled this and it led to his suggesting the adoption of the word "tank," which since has come into use in almost every language in the world.

The British decided to use the new tank corps to bolster a failing offensive on the Somme in spite of Swinton's arguments that it would be better to wait until more tanks were available. Out of 49 tanks, only 11 carried out the attack on Sept. 15, 1916. From then on, tanks were used in driblets and with little effect and often under unsuitable conditions because of military and political pressure. Yet their use raised Allied and lowered German morale. Not until the battle of Cambrai in Nov. 1917 were tanks used in mass. From then on they contributed greatly to reducing the previous heavy Allied casualties. (*See* WORLD WAR I.)

Production was increased largely through the organizing genius of Lieut. Albert (later Lieut. Col. Sir Albert) Stern. After the United States entered the war, Stern negotiated an Anglo-American treaty for building the components of Mark VIII tanks in both countries with assembly to take place in a factory furnished by the French.

The first British model, designated the Mark I, was produced in two types, a "male" weighing 31 tons and mounting two 6-pounders and four machine guns, and a "female" weighing 30 tons, mounting six machine guns. They were 26 ft. 5 in. long, 13 ft. 9 in. wide and 8 ft. 1 in. high, powered with a 105 h.p. Daimler water-cooled engine. Maximum speed was 3.7 m.p.h., with a fuel distance of 12 mi. They could traverse obstacles 4½ ft. high, span trenches 11½ ft. wide and climb a 22° slope. They used the rigid-type suspension on rollers, with steel tracks. Armour thickness varied from 0.2 in. to 0.4 in. A total of 150 Mark I tanks was built, and they were used in nine engagements, the last on Nov. 1, 1917. As early as April 9, 1917, at the battle of Arras, they were reinforced with the improved Mark II, and thereafter the British tank underwent constant development, the last major war model being designated the Mark V. In the last, specific improvements included an increase in speed to 4.6 m.p.h., an increase in maximum armour thickness to 0.47 in., and the substitution of a Ricardo 150-h.p. water-cooled engine, plus a better planetary-type transmission. In addition, the Mark V had twice the fuel distance possessed by the Mark I. A few Mark V Star tanks were used in combat by both British and U.S. units. These were simply the Mark V with a section built into the hull to lengthen it for greater trench crossing ability as well as to carry machine gun teams into combat. The Mark VIII was an improved version of this ve-

hicle.

During World War I the British also built a Medium Mark A or Whippet tank weighing 15.7 tons which carried a crew of only three men as compared with eight in the heavy tanks, and had greater speed and fuel distance than the heavy tanks. There later were a Medium B and a Medium C but these were available too late for combat.

French Tanks.—Though the British were the first to use tanks in battle, the French had actually preceded them in experimentation in this field. Much of this experimentation was civilian inspired. Instead of devices to defeat the German machine gun, effort initially was directed toward overcoming German barbed wire. Then, Col. (later Gen.) Eugène Estienne, like Colonel Swinton, saw an American Holt tractor and conceived an armoured fighting vehicle. In collaboration with Eugène Brillié, a Schneider engineer who had been experimenting with small Holt tractors, the Schneider C. A. or *char d'assaut* was successfully tested and placed in production.

Jules-Louis Breton, under-secretary of state for inventions, had been responsible for most of the earlier experiments. He succeeded in obtaining funds for proceeding with a larger vehicle designed by Col. Émile Rimailho of the St. Chamond firm and known as the *char St. Chamond*. Production was begun without consultation between the two groups. It was not until June 1916 that British developments in the new field were discovered. Premature British use of tanks on the Somme caused the French to rush production and the first units of *l'artillerie d'assaut* began equipping in Dec. 1916.

The first French tank attack took place in April 1917 and ended in failure. Committees bickered, and a change in high command shifted emphasis to artillery production. Nevertheless, Estienne succeeded in getting the Renault firm to design and build a light two-man tank. Another shift in high command resulted in a decision to cease building all vehicles but the Renault model. The first of these was shipped to the United States. Production was slow and it was not until the French were frightened by the German Chemin des Dames offensive that industrial production was pushed.

Although the French made many of the same mistakes as the British and there was considerable confusion over the role these new weapons of war would play, a great deal was accomplished. Jealousies existed but over-all there was less vacillation, with cancellations and reinstatements of orders, than occurred in England. The French had ordered 7,800 Renaults, of which 3,177 had been built by the end of the war, and 300 Char 2C, a 60-ton tank, of which only a few were completed. About 400 each of the Schneider and St. Chamond tanks were also built.

The Schneider and the St. Chamond were similar as to armament (one 75-mm. gun and two machine guns) except that the cannon was mounted in the right of the hull in the former and in the overhanging nose in the latter; speed was 6 m.p.h.; suspension was of the coil spring-bogie type; and tracks were of steel plate. The Schneider was lighter (14.9 tons compared with 25.3 tons) and smaller in over-all dimensions, the difference being accounted for by the bulkier power-transmission system used in the St. Chamond. This consisted of a four-cylinder 90 h.p. water-cooled engine with a dynamo and two electric motors, plus storage cells. In addition, the Schneider used a six-man crew, while the St. Chamond required nine men.

The Renault was armed with a 37-mm. gun or a machine gun, had a speed of 6 m.p.h., weighed only 7.4 tons, and was smaller in over-all dimensions than either of the other French tanks.

German Tanks.—Though the Germans had opportunities before and during World War I to take the lead in development of the tank, they failed to do so. It was not until the capture at Cambrai (Nov. 20, 1917) of a number of British tanks that the Germans possessed any serviceable armoured vehicles of this type. The captured tanks were assembled and repaired at Charleroi, where German experts studied them, but the idea of copying them was soon abandoned. Instead, reliance was placed on a model of German design which already was well along. A few of these were delivered in time to participate in the battle of St. Quentin on March 21, 1918, and in five additional actions before the Armistice in November. The Germans also used a few captured specimens in various actions, but they never had tanks in numbers at all comparable with those of the Allies.

The German model made during 1918 was built by the Daimler company. It was designed by Joseph Vollmer and known as the A-7V. It weighed 33 tons, was powered by two Mercedes-Daimler four-cylinder engines of 150 h.p. each, carried a crew of 18 men and mounted one 6-pounder gun and six machine guns. Perhaps its most interesting feature was the thickness of its armour, which varied from 0.59 in. to 1.18 in., and was designed to be proof against 37-mm. gunfire.

U.S. Tanks.—Before the United States entered the war, both the Holt Tractor company and the C. L. Best company had built some experimental tanks. As early as 1915, Cleve Shaffer proposed armouring and arming Fageol orchard tractors. At about the same time, E. M. Wheelock of Pioneer Tractor company and Norman Leeds of Automatic Machine company offered tank designs to the British and A. C. Hamilton of Oakland Motors built an experimental tank for the British at their request.

Committees created by Gen. John J. Pershing decided to obtain British and French tanks but interest lagged until the battle of Cambrai and the signing of the Anglo-American tank treaty to build the Mark VIII tank. With tremendous optimism, high production rates were forecast. The Mark VIII program failed partly because of the failure of the American aviation program since the same engine was to be used in both. The light tank program was equally bad. Pershing was notified in Feb. 1918 that these tanks would start arriving in France in April, yet at that time only a handful of people were working on the project and a contract had not even been let. By June it was evident that no American-built tanks would be available and so British and French vehicles were obtained. In return for the former, U.S. troops using British tanks had to serve in the British sector. Meanwhile, a Holt gas-electric, a Holt steam tank, an Endicott and Johnson steam tank, a Pioneer skeleton, a Ford one-man and a Ford Mark I three-man tank were being tested.

Efforts were finally concentrated on the copy of the Renault known as the 6-ton tank, on the Mark VIII and on the Ford one-man tank; but the first 6-ton tanks did not arrive in France until after the Armistice. At that time, 23,405 tanks were on order. Of these, 2,950 were Mark VIII, 4,400 were 6-ton, 1,000 were Mark I and the remainder Ford one-man. The Mark VIII was a larger version of the British Mark V, the Mark I was an improved Renault mounting both a 37-mm. gun and a machine gun. The Ford one-man tank weighed three tons, carried a machine gun and was very cheap to produce since it used many of the standard Ford Model T passenger car components.

U.S. tank units saw action in both the British and U.S. sectors and were under the over-all command of Gen. S. D. Rockenbach. Tank training in the United States was in charge of Lieut. Col. (later General of the Army) Dwight D. Eisenhower.

TANKS BETWEEN WORLD WARS I AND II

The plan for 1919, had the war continued, required a frontal assault by heavy tanks to achieve a breakthrough, with local exploitation by light tanks. This assault was to be followed by pouring fast medium tanks through the breaks, co-ordinated with aircraft attacks. Here was the real tactical lesson of World War I, but the victors retained only the memory of the war as it was fought with tanks and infantry in slow moving waves advancing under cover of a moving artillery barrage.

Voices were first raised in England against the accepted post-war tactics, principally by Col. (later Gen.) J. F. C. Fuller, author of the 1919 plan. He fostered the all-tank army and visualized land warfare resembling naval warfare. He was joined by Capt. B. H. Liddell Hart, who added the concepts of "tank marines"—tank-borne infantry co-operating with aircraft—and air-borne troops. They were joined by British Col. (later Gen.) G. LeQ. Martel, French Col. (later Gen.) Charles de Gaulle and German Col. (later Gen.) Heinz Guderian. However, the costs of the war and the quantities of tanks left over demanded economy, which

influenced subsequent vehicle development and tactics as well.

Because track life was short and there were demands for higher speeds behind the lines, there was considerable interest in combination wheel and track tanks, several of which were designed by J. Walter Christie in the United States. But eventually, as rubber bogie tires were adopted and track life increased, these were abandoned. The increasing popularity of the civilian passenger car brought about other mechanical improvements, many of which were also translated into tank design. Speeds increased as did radius of operation or fuel distance, air-cooled engines came into use, better suspensions were devised, intercommunication systems for crew members were developed, and Britain, in 1929, introduced short-wave radio for communication between tanks. Armament, however, remained light and seldom exceeded a 37-mm. gun or a heavy machine gun.

United States.—The National Defense act of 1920 eliminated the wartime tank corps and merged tanks with infantry. This action was of great influence tactically, as was peacetime economy. Interest in British tactical developments resulted in permission for the cavalry to work with "combat cars," a term coined to circumvent the law. A considerable period of bickering over appropriations and tactics resulted. A few experimental vehicles were developed which eventually resulted in an excellent and reliable M-2A4 light tank used by both infantry and cavalry, and an M-2A1 medium tank utilizing many light tank components was built for the infantry. Interest also was shown in the commercial Christie tanks, which could operate as wheeled vehicles by removing the tracks, but they were not considered sufficiently rugged for adoption especially since track life had reached 1,000 miles or more.

The M-2A4 light tank weighed 14 tons, had a crew of four and carried a 37-mm. gun and three machine guns. Its speed was 35 m.p.h. and its fuel distance was 100 miles. The M-2A1 medium tank weighed 23 tons and mounted a 37-mm. gun and light machine guns. The M-2A4 was of riveted construction; the M-2A1 medium tank was welded.

The German attack on Poland in 1939 caused a complete redesign of the M-2A1 medium tank and led to a large order for light tanks. The differences between the infantry and cavalry finally were buried in the creation of an armoured force on July 10, 1940.

Great Britain.—The British royal tank corps, though its existence was in doubt for a period immediately after World War I, continued as a separate arm. A few hundred Vickers medium tanks were built, larger versions of the French Renault but embodying many improvements. Martel and Carden Lloyd tankettes, originally intended to utilize passenger car components, came into use. These vehicles were used in a series of developmental tactical organizations along the lines suggested by Fuller and Liddell Hart. Eventually there resulted four major British vehicle types: the tankette for machine gun and mortar transport, the light tank for reconnaissance, the cruiser tank for independent long range strikes and the infantry tank for close infantry co-operation.

The first group resulted in the famous Bren carrier, the second in the light Mark VI tanks—fast, lightly armoured two-man vehicles in the five-ton class. The cruiser tanks were in the 20-ton class with speeds up to 30 m.p.h. These vehicles were developments of the U.S. Christie tanks. The infantry tanks weighed about 26 tons and had thick armour. The Christie and the infantry types were armed with a 2-pounder gun and one or more machine guns.

With the beginning of the rearmament program in 1938, the royal tank corps was consolidated with British mechanized cavalry units as the royal armoured corps, and its expansion went forward concurrently with the design of additional new tanks.

Germany.—Germany was denied the use of tanks, aircraft and heavy artillery by the victors of World War I. Thus in later years the Germans had a distinct advantage in not being saddled with a great deal of obsolescent equipment as was the case with its former enemies. The 1919 plan was studied and modified in the light of the later writings of Fuller and Liddell Hart. Where the official British and U.S. doctrine was that tanks were to be used to exploit the advantage after an enemy line was broken, and the French doctrine was slow moving, crushing fire power, the Germans adopted the view that tanks were properly used to obtain the breakthrough itself and tactics were worked out with dummy vehicles. After the Versailles treaty was abrogated, tanks were developed and openly displayed. The Germans concentrated on light and medium tanks of good design mounting slightly heavier armament than that used in other countries. Intervention in the Spanish Civil War worked out the details of German tactics and caused some modifications in design.

France.—The French experimented with a few tanks, and some modernization of wartime Renault tanks was undertaken after the war, but it was not until April 1926 that a new program for light, medium and heavy tanks was undertaken. Progress was slow until the Germans began to rearm in 1934. Even then, communist agitation and nationalization of war industries prevented as much progress as was intended. By 1939, nevertheless, approximately 3,000 modern tanks had been built. The French made notable progress in armour production; besides making considerable use of cast armour, they pioneered in work with welded armour. They were successful in combining thick, well-shaped armour with light suspension systems, thus holding down over-all weights. The French were among the first to use controlled differential steering, which permitted constant power to the track sprockets even when turning.

The principal French tanks built during the rearmament period were the 7-ton Renault AMR Type ZT armed with a light or a heavy machine gun, the 14-ton FCM armed with a 37-mm. gun and one machine gun. The former had riveted armour, the latter welded. Even greater numbers of squat Hotchkiss and Renault 13-ton tanks with cast armour were built. These mounted a 37-mm. gun and one machine gun. In the medium class, the Somua or Char 35-S mounted a 47-mm. gun and one machine gun. The heavy class included the Char B1, weighing 34 tons. The B1 had a 47-mm. cannon and a machine gun in the turret, a 75-mm. gun in the front of the hull and another machine gun in the rear of the hull. It was generally agreed that the Somua was one of the best tanks in any country at the start of the war.

U.S.S.R.—The Russian automobile corps was formed late in 1914 and many foreign automobiles were armoured in Russia and used in combat even against German trenches. British and French troops sent to Russia after the Revolution were equipped with tanks. These were given to the White Russians when the troops were withdrawn and later became the first tanks in the soviet army. A few experimental vehicles were built which copied foreign designs. Later, foreign vehicles were imported, including British commercial tanks and tankettes and a U.S. Christie. With the start of the first five-year plan in 1928 the Russians began creating designs of their own, based on these imports.

Soviet intervention in the Spanish Civil War permitted field testing of designs, but more real experience was obtained in the war with the Japanese on the Manchurian frontier in 1938–39. The poor quality of Russian gasoline led to the adoption of diesel engines of German origin, and German torsion bar suspensions also were incorporated into Russian tanks. The Russo-Finnish War showed shortcomings in design although existing light and very heavy vehicle production could not be shut off immediately.

The Russians began World War II with a light T-26 tank copied from the British Vickers-Armstrongs 6-ton tank, small amphibious tanks, BT tanks developed from the U.S. Christie, several medium tank varieties and a few heavy tanks. The numbers were greater than those possessed by the Germans but the quality was not good and they were poorly handled. The T-26 tank existed in two models, one with a single turret mounting a 47-mm. gun. The other had twin turrets, each mounting a machine gun. The light amphibious tanks carried machine guns. The 11-ton BT tanks were armed with a 47-mm. gun. Both T-26 and BT varieties had been used in Spain. The T-28 and T-32 were medium and heavy types with multiple turrets mounting machine guns and short cannon either of 47-mm. or 76-mm. calibre.

Other Nations.—Most of the smaller nations purchased tanks from other countries, principally Great Britain, France, Sweden and Czechoslovakia. The first Swedish tanks were built from parts

for German LKII light tanks shipped to Sweden after World War I and assembled under the direction of Joseph Vollmer, who had designed them originally. Spain built a few tanks of local design and the Czechs produced tanks for their own use as well as for export. The Japanese for some time used tanks purchased in Britain and France. In 1928, locally designed light, medium and amphibious tanks began to appear, some used by the army and some by the navy. Japanese tanks had considerable interchangeable parts, were thinly armoured and used diesel engines.

Poland, Austria, Australia, Belgium, Hungary, Canada and India produced some vehicles of their own design and others under license from other countries. Italy copied the French Renault near the end of World War I and built a few heavy tanks. The light Fiat copies of the Renault continued in use after the war. Later, British Carden Lloyd tankettes were built under license and evolved into a smaller vehicle, the CV 3/35. Experience gained in Ethiopia and in Spain in 1935–36 led to the design of the Italian M-39 medium tanks, lightly armed and armoured. Both were in use at the beginning of World War II.

WORLD WAR II

The Spanish Civil War had demonstrated the deadliness of a concentrated attack sustained in depth on a narrow front. It was the method used by the Germans in attacking Poland in 1939. Tanks and dive bombers were given the primary role in achieving deep, fast-moving penetrations. Motorized infantry followed close behind. The campaign was a brief dress rehearsal for invasion of the Low Countries and France the following year. French and British tanks outnumbered the German tanks but were widely dispersed in accordance with the French principle of close infantry support. German tactics of punching in mass on narrow fronts made the most of the opportunity and the campaign was soon over.

From France, the war moved to North Africa. There the tactics were similar to the naval tactics originally envisioned by General Fuller. When Germany attacked Russia, its previous tactics were not as successful. The Germans used 2,400 tanks against the Russians' 24,000. Within three months the Russians had lost 17,500 tanks and the Germans 550, but the areas were great and the Russians traded land for time. The Germans had made an organizational change which weakened their thrusts. In 1939 there had been 300 tanks per armoured division. To attain what Hitler believed would be greater mechanized fire power, more armoured divisions were created with fewer tanks per division, but these units lacked punch.

The British and U.S. forces copied German organization and followed this change also. The Russians learned by experience. When they resumed the offensive at Stalingrad, the Russians had more tanks and aircraft and applied successfully the tactics the Germans had used in France. Differences in tactical concepts were reflected in the designs produced by different armies—the Germans particularly tending as the war went on to build more heavily armed and armoured monsters, sometimes at the expense of mobility and mechanical reliability. The days when strategic surprise with large masses of armour was possible for one or another opponent gave way to fierce encounters between forces more equally matched in armour. Numbers, skill and daring were still to prove decisive in many actions, but the tank design race became one essentially between projectile and armour.

Early in the war, tanks received a great deal of publicity. They were spectacular and many people in and out of military service became conditioned to their success. Later, in certain theatres where areas for maneuver were circumscribed, people jumped to the conclusion that tanks were obsolete. Yet right up to the end of the war the issues between the Germans and Russians were largely decided by tanks and self-propelled artillery. The tank served most usefully in World War II when employed in mass on suitable occasions by commanders who fully appreciated what it could and could not do. Again, it was most effective when used as a member of an integrated team including all the other ground arms and supported by suitable aircraft.

Germany.—After the Germans overran Czechoslovakia, they took over production of Czech TNH tanks, calling them 38 (t). German production was fairly well centralized and between 1939 and 1942 no overtime was worked. After the United States entered the war the first real attempt at economic mobilization was made, but it was not until 1944 that Albert Speer, then chief of production, was given power to forbid design changes which would interfere with production.

Hitler, either directly or indirectly, made many engineering decisions, sometimes on obscure details. In spite of the German totalitarian government, there was much extravagance in the number of vehicle types and in design complications, in addition to the tremendous use made of modified captured vehicles. Allied bombing caused some dislocation of production but, from 1940 to 1944, German tank production increased tenfold, then it fell, but only partly due to bombing. Other factors were oil shortage, use of slave labour, transportation difficulties and extravagance in man hours due to lack of knowledge of mass production methods.

Between 1939 and 1944, Germany produced 42,932 armoured vehicles. As the war forced the Germans more and more on the defensive, the trend was toward the armoured assault gun and huge tank destroyers rather than tanks because more of the former could be produced for the same effort. The Germans began the war with tanks mounting heavier armament than those of the Allies and during the war they constantly increased these calibres. Armour was also constantly thickened, it being a principle that the armour of a tank should be proof against the weapons it carried. Although many vehicle types were produced, the best of the German tanks probably was the Panther, which was developed after encountering the Russian T-34. The German vehicle was superior to the Russian except in mechanical reliability. The Panther had thick, well-sloped armour of welded construction. The main armament was a high velocity 75-mm. gun. This tank weighed 47 tons and had a speed of nearly 30 m.p.h. The Tiger, a heavier and somewhat slower tank, mounted an 88-mm. cannon. Late in the war, still heavier tanks mounting high velocity cannon up to 128 mm. were in use and even larger tank guns and new tanks were being tested.

United States.—After the German invasion of Poland, rearmament started in the U.S. but there was considerable confusion. The extent and need for arming were as vague as were the possible theatres of war should the United States become involved. Existing mobilization plans had to be scrapped, and lend lease added to the confusion. After Pearl Harbor on Dec. 7, 1941, the president set up production goals so great that U.S. industry was aghast but willing to try to meet them. In spite of the president's demands that heavy tanks be produced and although the heavy M-6 tank design was available, the project was canceled because the new armoured force did not want a heavy tank and preferred to use available shipping space to ship twice as many medium tanks.

There was a great deal of bad blood between army service forces and the civilian War Production board but, in spite of the conflict between them, production was prodigious. There were 287,425 combat vehicles built during the war, together with enough spare parts to have built half again as many more.

The original M-3 medium tank had a 75-mm. gun mounted on the right front of the hull with machine guns in the bow and a 37-mm. gun and machine guns in the turret. This tank was known as the General Lee. When it was fitted with a more squat British turret, it was called the General Grant. It was produced with riveted, cast and welded armour and with different types of engines because of production limitations. Many of its limitations were overcome in a design which followed.

The M-4 medium tank, known as the General Sherman, with added armour and the 75-mm. gun in the turret, was in production by April 1942, and it reached Africa in time for the battle of El Alamein. Undergoing continual development during the war with 76-mm. guns on a 105-mm. howitzer on some models, the M-4 became by far the most widely used Allied tank in the war. A total of 49,234 was produced. Its components featured simplicity and ruggedness. Of particular interest were the volute spring bogie-type suspension, the highly developed V-8 engine and the rubber-block, rubber-jointed tracks. A life of 3,000 mi. was not unusual

for these tracks, compared to about 600 mi. for the metal-jointed German tracks. Aside from the fact that the numbers of the Sherman tank supplied to Allied armies made possible the massing of superior tank forces in critical areas, its speed, maneuverability and capacity for sustained operation under severe conditions made the Sherman tank a vital factor in Allied victory.

Late in the war a compromise between the medium Sherman and the heavy M-6 was made in the 45-ton General Pershing. It mounted a 90-mm. gun, used torsion bar suspension and a torquematic stepless transmission. A few reached Europe before the war ended and some later also were landed on Okinawa. Light tanks went through a similar process of gun calibre increase and the application of automatic transmissions adapted from motorcar design. The culmination of these was the M-24 or Chaffee 23-ton light tank, named after Brig. Gen. A. R. Chaffee.

The navy and marine corps had tested Christie amphibious tanks a few years after World War I. This led to a new concept in amphibious landings which received another impetus when the Roebling rescue machine came to their attention in 1939. As the war went on, those vehicles were refined. Beginning with the marine corps landing on Betio (Tarawa), they were used more and more by the marine corps and eventually by the army. They were propelled in water by the motion of their tracks. Finally they were armoured and later turreted. Some were used as personnel carriers and some as accompanying artillery in landing operations. About 18,620 were built during the war.

Great Britain.—Immediately following the German invasion of Poland some members of the original World War I tank committee received permission to form a new committee at the ministry of supply. They produced a heavy gas-electric TOG tank, its initials representing "The Old Gang." The ministry meanwhile released for production a heavy Vauxhall tank. Disputes followed between Winston Churchill, then prime minister, and the committee with the result that the committee was dissolved and the Vauxhall tank became the 40-ton Churchill heavy tank.

Almost all existing tanks were lost at Dunkirk. To catch up, vehicles were released for production with little testing. By the time the "bugs" were worked out, the tanks were obsolete. British tanks had a poor reputation because of this and because of lack of production inspection and control. Parliament investigated but was unable to fix responsibility. Meanwhile, production continued. The British purchasing commission in the United States contracted to build tanks similar to the American medium M-3 designed after the invasion of Poland. Near the end of the war, British tank quality had improved and weapon calibres were more nearly the equal of the Germans.

Final models of the Churchill and Cromwell mounted 75-mm. guns. The faster and lighter Comets mounted 77-mm. guns. The Cromwell and Comet were in the cruiser class. In addition to combat tanks, the British devised several self-propelled guns and many special tanks such as the A.V.R.E. for throwing high explosive petards, "flails" for detonating land mines, carpet-laying tanks or "bobbins," flame throwers and others. About 24,000 tanks were produced, 3,600 were received from Canada and the United States furnished 25,600.

U.S.S.R.—The models laid down in 1938–39 and produced by 1940 revolutionized Soviet armour. The 26-ton T-34 medium was one of these. It was of the Christie type with wide (24 in.) tracks, had a low silhouette and a 30 m.p.h. speed provided by a good 500 h.p. liquid-cooled diesel V-12 engine. It was armed with a 76-mm. gun and later with an 85-mm. gun.

Another 1940 model was the KV heavy (named for Kliment Voroshilov, soviet minister of defense), which weighed 52 tons and mounted a 76-mm. gun. The KV was much more heavily armoured than the T-34, which accounted for its greater weight, since in other respects it was much like the T-34. With these early wartime models the Soviets came into their own as designers, producers and users of fighting tanks. Before the war's end another heavy tank, the Joseph Stalin, was to appear. It was a logical step from the T-34 and the KV, in the progression toward thicker armour and more fire power, with the 51-ton JS-2 model mounting a 122-mm. gun.

In addition to Russian production of about 100,000 vehicles, the United States furnished Russia 13,303 combat vehicles (tanks, self-propelled weapons and scout cars) under lend lease. The British furnished 4,260 and Canada 1,220 tanks in addition to huge numbers of Bren carriers from both. Figures for Russian tank losses in the war have never been released but are believed to have been in the neighbourhood of 100,000. Russian equipment was designed to do the job with the least possible expenditure of man-hours to produce, with simplicity and with absolutely no emphasis on finish or crew comfort.

TANKS AFTER WORLD WAR II

Satellite nations and those friendly to the U.S.S.R. were supplied with Stalin III heavy tanks. These were developments of the original KV but with sloping armour and a dome-shaped turret mounting a 122-mm. gun. T-34/85 tanks mounting an 85-mm. gun in place of the original 76-mm. gun also were furnished to these nations. Russian troops were rearmed with the T-54, similar to the T-34 but with a domed turret and a 100-mm. gun. A new amphibious tank also appeared in 1956, followed by air-borne and rocket projector tanks in 1957. In addition to an estimated 50,000 tanks, the Russians had at least as many self-propelled guns which had been brought to a high state of development by the end of World War II.

Great Britain dropped the basic subdivision between cruiser and infantry tanks in favour of a single-purpose medium tank, the Centurion. This tank was also furnished to Sweden, Switzerland and some members of the North Atlantic Treaty organization (NATO). A still larger Conqueror was also in use in Britain. The United States continued development of the General Pershing class with a cross-drive transmission. This culminated in the M-48A2 Patton mounting a 90-mm. gun. Rounded cast armour and a new air-cooled engine with direct fuel injection were features. The navy and marine corps also continued development of LVT's, or tracked landing vehicles. The United States gave many tanks to friendly nations.

France produced a light AMX 13-ton tank as well as a few heavier vehicles. The former were also sold to Sweden, Switzerland and other countries. Czechoslovakia began producing tanks, selling them to Egypt and other countries. Sweden continued to produce tanks for use at home and for export. Yugoslavia built tanks resembling the Russian T-54. Communist China, furnished tanks by Russia, began producing tank parts.

Tanks were used in combat in the Arab-Israeli wars of 1948 and 1956 and also in Korea in 1950. In the first case they were badly handled. In Korea, terrain dictated greater use as self-propelled artillery than as tanks.

TANK DESIGN

Great advances have been made in tank design since the World War I period. Principal among these improvements were track life, fire power and sighting equipment, suspensions, armour and armour shape, speed, reliability, standardized components and the development of vehicle "families."

It once was the custom to refer to tanks as light, medium or heavy. In the late 1950s it would be more accurate to classify them as light gun, medium gun or heavy gun tanks. The effectiveness of a tank is measured by its ability to bring fire to bear on an enemy and to make such fire mobile. A self-propelled gun is classed the same way, but it usually lacks complete armour protection. Tank guns are fitted with muzzle brakes which tend to shorten the recoil. Bore evacuators also are used to suck the combustion gases out of the muzzle, thus keeping the gases out of the crew compartment. High velocity guns erode after firing relatively few rounds. United States gun designers found a way to replace liners in the field with but a few simple tools, which was a great step forward.

Tank guns were augmented by gyroscopic gun or turret stabilizers which kept the gun on target regardless of vehicle motion; by automatic range finders; by turret "baskets" which revolved with the weapon and crew; and by vision cupolas and periscopes to offset blind spots.

If armour protection were absolute, the weight would be so great the vehicle could not move. Armour thickness, therefore, is arranged to be greatest at the most vulnerable points; or rounded or angular surfaces are used to deflect fire. As it is, armour weight represents over one-third of total weight. Thus design becomes a compromise between intended armament, vehicle weight and engine horsepower. Tanks were designed to be capable of operating in extremes of temperature, to be completely waterproof, fungusproof, with low noise level, high crew comfort and capable of being maintained even though the crew members wore mittens. Additional equipment included gyrocompasses, infrared sighting equipment and electronic navigational equipment which required adequate electrical generating and storing equipment.

It can, therefore, be seen that design of a tank is no simple engineering

task. The modern tank is expensive and complex and requires over 40,000 blueprints. Experiments indicate that new metals or alloys will permit an armour to be produced which will be 40% lighter in weight with no sacrifice in strength. Smaller power units also may lead to reaching the military goal of air transportability.

FUTURE OF THE TANK

With the advent of atomic missiles the concept of war underwent a complete change. Following a period of confused thinking, military concepts began to crystallize after 1950. Land warfare in the atomic age was believed most likely to take the form of thin screens of guerrillas or skirmishers with sudden concentrations and attacks and equally quick dispersions occurring constantly.

Quick exploitation before an enemy recovers his balance after an atomic blast was considered to be of great importance. Tanks were thought to be well suited for use in atomic warfare because of the protection offered their crews from heat and flash. Their mobility would enable them to disperse and to reconcentrate rapidly as changes took place in a tactical situation either by the threat of or the use of nuclear missiles. Infantry might be too slow and too vulnerable for such activity, and probably would be carried in armoured personnel carriers accompanying tank formations.

Co-ordinated with aircraft and airborne troops, armoured troops would continue to be forces to be reckoned with in land warfare, whether or not atomic missiles were used.

TANKER, a ship designed to carry liquid cargo in bulk. Its cargo is usually a petroleum product, either crude oil being carried from oil fields to refineries or gasoline being carried from refineries to distribution centres. The liquid is piped into the cargo space of the ship and is transported without use of barrels or other containers. Special tankers carry other liquids such as

FIG. 1.—SMALL TANKER (2,750-TON DEAD WEIGHT) USED ALONG THE EAST COAST OF THE U.S.

molasses, asphalt or even wine, but the references in this article are all to oil tankers. Tankers differ from general-cargo ships in that they normally carry a full load of cargo in one direction and return without cargo.

Tankers vary in size from small coastwise vessels about 200 ft. long, carrying from 1,500 to 2,000 tons dead weight, up to huge vessels which are the largest ships afloat, approaching 1,000 ft. in length and carrying over 100,000 tons dead weight. ("Dead weight" is the total weight that a ship can carry, consisting primarily of cargo but including fuel, water, crew, stores, etc.) Up to 1940 the upper limit in size was about 15,000 tons dead weight and about 500 ft. in length. In 1948, 28,000-ton "supertankers" appeared, followed in quick succession by tankers of 40,000, 60,000 and (in 1958) 100,000 tons. By the latter date there were more than 3,000 tankers of over 1,000 tons dead weight in the world, with a combined carrying load of more than 48,000,000 tons.

Experience with supertankers has shown that the direct cost of transporting oil goes down as the size of the tanker increases, apparently without limit; the only reason for not building larger tankers is the lack of suitable shore facilities for them. As deep-water loading and unloading facilities are created, larger and larger tankers will probably become economically feasible.

FIG. 2.—BELOW-

The speed of tankers has increased along with their size. In 1940 most tankers were powered with not over 5,000 shaft horsepower and made from 12 to 14 knots. In the 1950s most large tankers were given from 15,000 to 25,000 shaft horsepower and made from 15 to 18 knots.

Arrangement.—Tankers almost invariably have their propelling machinery located in the stern. (*See* fig. 2.) The cargo-oil space occupies about 60% of the ship's length; usually there is a general-cargo hold in the bow, along with ballast or fuel tanks. The cargo space is isolated from the forward and after portions by cofferdams, watertight compartments which are kept empty. A pump room is located just forward of the machinery space, with sometimes an additional pump room forward or amidships. There is a "forecastle" (additional topside deck at the bow) and a house amidships, containing the pilothouse, other navigational spaces and usually quarters for a few of the crew. A "poop" (additional topside deck at the stern) extends over the machinery space and, together with higher levels of deckhouses, quarters the rest of the crew. The cargo space is usually divided into two, three or four rows of cargo tanks by longitudinal bulkheads; these are further divided into individual tanks (from 35 to 40 ft. long in large vessels) by transverse bulkheads. Access to the tanks is through oiltight hatches on the deck. Tankers differ from most seagoing vessels in that they do not have a double bottom in the cargo spaces.

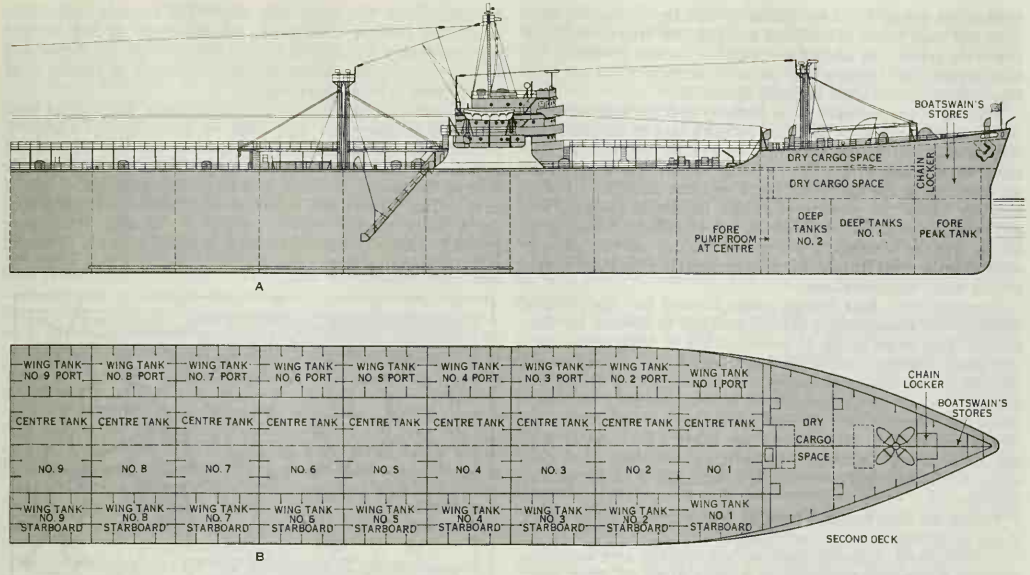
FIG. 3.—MEDIUM-SIZED OCEAN-GOING TANKER (27,000-TON DEAD WEIGHT) OPERATING BETWEEN VENEZUELA AND NEW YORK



DECK ARRANGEMENT OF A TANKER: (A) PROFILE; (B) PLAN VIEW SHOWING CARGO TANKS

Tanker crew accommodations are more livable than those of most vessels, because of the limited leave-time, which is often only about one day per passage. Single-person rooms, recreation lounges, and even swimming pools are fitted on the long-voyage tankers to enhance crew morale.

The density of the cargo carried by tankers varies from about 40 to over 60 lb. per cubic foot. A tanker with enough capacity for a full dead-weight cargo of light gasoline will have some empty tanks when carrying a full cargo of heavy crude oil.

Tankers are permitted by law to load more deeply, in proportion to their depth, than ordinary cargo ships. To be permitted this greater draft, they must provide special arrangements for fore-and-aft access for the crew in heavy weather, and for the quick freeing of the deck of seas which wash over it. The draft of tankers plying between the Arabian oil fields and Europe or the Atlantic coast of North America is limited by the Suez canal to 35 ft. For tankers of usual proportions this draft corresponds to about 30,000 tons dead weight. The extremely large tankers may be designed for drafts of 40 to 45 ft., and could not use canals if fully loaded. A relatively high block coefficient is used to obtain maximum dead weight. The block coefficient is the ratio of submerged volume to the product of length, beam and draft. The coefficient is frequently as high as 0.80, compared with about 0.60 to 0.70 for many passenger vessels and about 0.70 to 0.75 for most general-cargo ships.

FIG. 4.—LARGE TANKER (60,000-TON DEAD WEIGHT) USED IN TRANS-ATLANTIC SERVICE BETWEEN THE PERSIAN GULF AND PHILADELPHIA

Construction.—The internal bulkheads, and the stiffening members, are usually entirely welded. The outside plating (shell and deck) is also welded but in large tankers a few fore-and-aft seams are riveted. It has been found that a riveted seam will usually stop a crack in the plating, thus preventing a minor crack from becoming a major fracture. Small tankers may be completely welded.

The upper deck and the bottom shell of tankers are invariably framed longitudinally; that is, the stiffening members which support the plating are run fore-and-aft instead of transversely as in other types of ships. In many tankers the side shell plating is also longitudinally framed. The thickness of the shell plating will vary from about $\frac{3}{4}$ in. for a small tanker to about $1\frac{1}{2}$ in. for a very large tanker.

Tankers are shorter-lived than most steel ships because of the corrosive nature of their cargo. Crude-oil cargoes deposit corrosive sludges on the bottom and gasoline cargoes emit corrosive vapours against the deck overhead. As a result, a tanker may last only 12 years instead of the 20-year life of a cargo ship.

This deterioration takes place mainly in the cargo spaces, leaving the bow, the stern and the machinery with years of useful life. It is, therefore, not unusual for an owner to scrap the cargo-tank portion of an old tanker and have a new one built and fitted into the old bow and stern. Since the new part is usually made larger than the discarded section, this procedure is sometimes called "jumboizing."

Protective coatings have been developed that will withstand the corrosive effects of petroleum products, but they are in general so expensive that many operators leave the interior of cargo spaces in tankers unpainted. For the tanks that are used for salt-water ballast on the return voyage, electrolytic preservative systems using sacrificial anodes of magnesium are sometimes employed.

TANNENBERG, BATTLE OF. No portion of the earth's surface has been more fought over than East Prussia. It was in 1410, on the field of Tannenberg, that the Teutonic knights were utterly routed by their enemies the Poles and Lithuanians, and the German victory of 500 years later was in some degree the reversal of this defeat.

The Tannenberg of 1914 was the greatest victory achieved by any of the combatants at the beginning of World War I, and its strategic and moral effect upon the struggle was far-reaching.

France and Russia had been joined by military convention since 1892 and their chiefs of staff had made careful arrangements for concerted action. In case of war with the Central Powers it had been agreed that Germany was the main enemy and that the principal military effort must be made against it.

Because of the vastness of its territory and the comparatively undeveloped state of its railways, Russia's rate of concentration was considerably slower than that of France, so much so that there was a danger of the latter's being crushed before the attack on Germany in the east could begin to exert its effect. Unfortunately, under the pressure of French insistence, the good will and optimism of Russia's military leaders exceeded practical possibilities and the outbreak of war found Russian military plans in some disorder. All Russia's initial operations in East Prussia were in fact hasty improvisations.

Geographically, East Prussia points forward into the heart of Slavdom and constituted a difficult problem of defense for Germany. True to its policy of concentration of force at the decisive point, Germany had decided to advance against France with its main forces while maintaining only a minimum of strength in the east. Not wishing to abandon national territory without a blow, the Germans had decided to concentrate this minimum strength in East Prussia, despite the dangers involved in such action. Germany's strength in the east was to consist of 11 divisions, 6 first-line and 5 second-line, with but a single cavalry division.

Taking the East Prussian front as it appeared to the Russians, it can be divided militarily as follows:

1. *Königsberg Area.*—A more or less fortified area extending over the Königsberg peninsula, of a depth of 19 mi. from north to south. In the centre lay the obsolete fortress, strong against anything but heavy artillery. The area could be reinforced by sea through the canal from Pillau. It formed a strong flanking position from which to attack any force to the south.

2. *Insterburg Gap.*—A gap of 43 mi. of open country, down which ran the main Insterburg-Allenstein railway. The River Angerapp running north and south blocks this gap. It formed an excellent line of defense with the right flank resting against the impassable Lake Mauer.

3. *Masurian Lakes.*—A line of continuous lakes from Angerburg to the Russian frontier at Johannisburg, a distance of 50 mi. The narrow gaps between the lakes could be held with few troops, and the whole line presented an almost impregnable front behind which the Germans could operate to either flank.

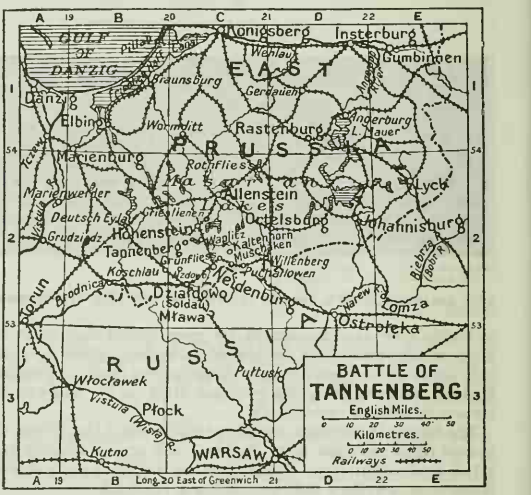
4. *Johannisburg-Dzialdowo (Soldau) Front.*—A distance of 75 mi. running east and west. On the Russian side the country had been left a desert as a defense against Germany.

The Russian Plan of Invasion.—The Russian plan for the invasion of East Prussia was to advance with two armies north and south of the line of lakes, with the object of enveloping the German forces supposedly concentrating behind this line. The northern army under Paul Rennenkampf was to advance first, toward the Insterburg gap, with the object of drawing the Germans as far to the east as possible. The southern army under Alexander Samsonov was to advance to the line Rastenburg-Allenstein, with the object of striking the rear of the Germans opposing Rennenkampf.

Rennenkampf's army crossed the frontier on Aug. 17 with a strength of six and one-half divisions and five and one-half cavalry divisions. On Aug. 20 an action was fought with the German 8th army at Gumbinnen. Max von Prittwitz und Gaffron, the German commander in the east, had concentrated his main strength to meet Rennenkampf, six divisions and a cavalry division, while leaving about two divisions to face Samsonov's army, which was concentrating on the River Narew.

Rennenkampf had moved off without a great portion of his transport and found himself forced to halt on Aug. 20. Prittwitz advanced to attack him. There were serious miscalculations in the German movements, with the result that the action was indecisive, both sides suffering heavy losses. That evening the news arrived that Samsonov had not only started to advance, but that two of his corps were already close to the frontier and that he had at least five corps with him. The German commander abandoned all hope of defeating Rennenkampf on Aug. 21 and contemplated a withdrawal to the Vistula. On communicating this on the telephone to the supreme command, he and his chief of staff were at once superseded.

The new commander, Paul von Hindenburg, had not yet been employed in the war. His chief of staff, Erich Ludendorff, reached supreme headquarters at Coblenz on Aug. 22 and the situation in the east was explained to him. He immediately ordered the troops retreating in front of Rennenkampf to halt at once and to prevent him from pursuing, and issued instructions for a concentration against Samsonov. General Hindenburg joined Ludendorff's train at Hanover and took over the command at Marienburg on Aug. 23.



Luckily for the new command, Max Hoffmann, the chief of the operations section under Prittwitz, had already carried out many steps facilitating the concentration desired by Ludendorff, and the situation, though alarming, had not grown worse since the supersession of Prittwitz. Samsonov's right was indeed well over the frontier near Ortelsburg and his left between Neidenburg and Dzialdowo (Soldau), but the Russian advance appeared to be slowing up. The German 20th corps had taken up a position north of Neidenburg and was awaiting attack. The leading units of the 1st corps were detraining south of Deutsch Eylau and were moving up on the right of the 20th corps. The 3rd reserve division had detrained at Allenstein and was moving up on the left of the 20th corps. A landwehr division and units from the Vistula garrison troops were also coming up. Thus, a strength of about six or seven divisions had been collected to oppose ten divisions and three cavalry divisions of Samsonov's army.

No decisive results could be expected from such strength, and decisive operations were the Germans' only hope. The most important feature of the situation, however, was that Rennenkampf had made no forward move since Gumbinnen and had lost all touch with the enemy in front of him. Ludendorff therefore conceived the idea of withdrawing all the troops from Rennenkampf's front, with the exception of the cavalry division, and of directing them against the right flank of Samsonov's army. Another four divisions thus obtained would give him an actual superiority over Samsonov and the direction of their attack might indeed be decisive.

An Account of The Battle.—Samsonov, who in peacetime was the governor general of Turkistan, had arrived from sick leave in the Caucasus on Aug. 12. He had seen neither his subordinate generals nor his staff before, and his immediate superior, Jilinsky,

commander of the northwestern front, was urging him forward to cross the frontier on Aug. 19. The original concentration areas of his army behind the Bobr and the Narew had been considered to be too far to the east and a general move of all corps to the west was in progress. By Aug. 20, the right wing (6th and 13th corps) had reached the frontier, with the 4th cavalry division well behind on the right. The left wing (15th and 1st corps) was just short of the frontier, with the 6th and 15th cavalry divisions covering it. Of the 23rd corps, one division was two days' march behind the left wing and the other had not yet detrained at Warsaw. The troops had been marching for a week across the desert area north of Ostroleka, over execrable roads in very hot weather. Much of the transport had been left behind, the men were tired and unfed and numbers had been much reduced by sickness. No contact had been gained with the enemy and the army was already more than 24 hours late in crossing the frontier. Reports from Rennenkampf of his victory at Gumbinnen and, during his advance westward on Aug. 24 and 25, of the signs of a hurried retreat on the part of the Germans, brought further urgings from Jilinsky to Samsonov to hurry. Samsonov obeyed to the best of his ability, and by the morning of Aug. 26 his position was as follows:

His centre of two corps (13th and 15th) was advancing northwest and was close on the line Allenstein-Hohenstein. On his right was one corps (6th) and the 4th cavalry division at Rothfliess, at two days' march from the centre. On his left was a corps (1st) and the 6th and 15th cavalry divisions near Koschlau, at one day's march from his centre. The 23rd corps troops which were up were moving into the gap between the centre and the left. His forces were thus much dispersed.

Reconnaissance had been bad and Samsonov had little information as to the enemy's dispositions. He seems to have thought that the Germans flying in front of Rennenkampf had already crossed his front in their march to the Vistula and that he was too late to cut them off. He had deviated from his instructions to advance with his left on Allenstein and now had practically the whole of his force to the west of that town. He had no knowledge of the whereabouts of Rennenkampf's army and did not realize that he was increasing the space between the two Russian armies and thereby facilitating the German operations. His supply system had broken down utterly and his men were half famished and worn out with the fatigue of excessive marching. The signal service had also broken down and orders had been sent out to corps by wireless. The Russian signals were easily read by the Germans, who thus had absolutely accurate information as to their opponents' dispositions and intentions.

Germans Attack Samsonov.—The new German command had galvanized the dispirited 8th army from the first and hope of success ran high. The attacks on Samsonov's two flanks were to be launched simultaneously on Aug. 26. On the right, the German 1st corps, strengthened by the Vistula garrisons, attacked only halfheartedly. Hermann von François, the commander of the 1st corps, was short of some of his heavy artillery and he contented himself with driving in some of the Russian outposts. On Aug. 27, however, he launched his attack in earnest. At dawn a hurricane bombardment was opened on the Russian 1st corps's positions on either side of Uzdowo. The famished Russians did not wait for the infantry attack but broke and ran. By 10 P.M. that night there was nothing left of the Russian left wing except a small rear guard just north of Dzialdowo; and that too had disappeared before the next morning.

The rear of the Russian centre was now completely exposed and François directed his march on Neidenburg. Opposition there was none, and by the night of Aug. 28 his leading troops had reached Muschaken, eight miles east of Neidenburg. By the night of Aug. 29 the whole length of the road from Neidenburg to Willenberg was held by a line of entrenched pickets. The Russian retreat to the south was completely blocked. During Aug. 30 François was attacked at Neidenburg by fresh Russian troops coming up from Mlawa and actually lost the town for a time. He held stoutly on to the line of his pickets, however, and on Aug. 31 Neidenburg was reoccupied.

On the left, the German 17th and 1st reserve corps, having turned their backs on Rennenkampf and marched due south, had arrived within striking distance of the Russian right at Rothfliess on the night of Aug. 25. Their attack on the morning of Aug. 26 came as a complete surprise. The Russian 6th corps withdrew in confusion, losing 6,000 men and 16 guns. By the night of Aug. 27 the Russian right was 32 mi. S. of Rothfliess and in a state of hopeless demoralization. The rear of the Russian centre was now exposed on its other flank. The German 17th corps continued its march to the south, while the 1st reserve corps moved in closer toward Allenstein. The story of the fighting in the Russian centre is not so inglorious as that on the two flanks. In accordance with Samsonov's plan the centre (13th and 15th corps) continued their advance on Aug. 26 toward the line Allenstein-Hohenstein. The 13th corps encountered no opposition, but the 15th had to fight its way steadily forward. For Aug. 27, the advance was to be continued.

Second German Blow.—Ludendorff, with his accurate information of the events on either flank, now decided that the German centre had retired enough. The reinforced 20th corps was therefore ordered to attack on Aug. 27. The battle which ensued between the Russian 15th corps and the German 20th corps was particularly fierce, the Russians holding their own and even advancing a little on their left. The Russian 13th corps rendered no help to its neighbour. On Aug. 28 the Germans renewed their attacks and this time the hardly tried Russian 15th corps commenced to break. The 13th corps, moving down to assist, found itself assailed in the rear by troops arriving from Allenstein and for the second time brought no help.

When night fell the two Russian corps were on a line from Grieslienen to Waplitz and in close touch with the Germans. Hoping to escape from pursuit, they began to withdraw during the night. The withdrawal soon became a rout, and a mass of troops and transport, both unfed and unwatered, became inextricably mixed in the depth of the Forest of Grünfliess. Determined attempts were made during Aug. 29 to break through to the south of Muschaken and to the north at Kaltenborn, but the German ring held fast. Only about 2,000 men effected their escape. The greater portion of these two corps surrendered to the German parties clearing the forest during Aug. 30 and 31.

Samsonov himself had moved up to Neidenburg on Aug. 27 in order better to control the battle. He was greeted with the news of the disaster to both his flanks and met streams of stragglers coming into the town. He decided to go to the headquarters of the 15th corps and take personal charge, and left Neidenburg on the morning of Aug. 28 with a small staff, all mounted on horses. At once he became mixed in the mass of transport in the forest and could exercise no effective command. He then decided to ride to the south, but during the night of Aug. 28–29 he became exhausted after having walked for some distance. He drew aside in the darkness and his staff heard a single shot. A careful search brought no result and the staff continued its way, certain that its unfortunate commander had taken his own life in his despair at the turn which events had taken.

Results.—The practical result of the fighting from Aug. 26 to Aug. 30 was the total annihilation of two Russian corps and the reduction of three other corps to half their strength in numbers. The whole Russian 2nd army was so demoralized and was so deficient in essential material, such as artillery and transport, that it was no longer of any fighting value. The Germans claimed 125,000 prisoners and 500 guns. It is certain that their booty was very great, for 60 train loads of captured material left Puchallowen after the battle and the captured horses were driven in herds to improvised camps at Neidenburg. Although greatly inferior in the whole eastern theatre, the Germans had yet managed to concentrate a superiority on the field of battle. The Russians had 132 battalions, 96 squadrons and 620 guns, including 12 heavy, while the Germans had 155 battalions, 48 squadrons and 818 guns, including 128 heavy.

TANNER, HENRY OSSAWA (1859–1937), U.S. Negro painter, whose style was naturalistic and whose subject matter was most often biblical, was born at Pittsburgh, Pa., on June 21, 1859. He was the son of BENJAMIN TUCKER TANNER (1835–1923), bishop of the African Methodist Episcopal Church from 1888 to 1908 (when he retired at his own request) and author of a number of books, including *An Apology for African Methodism* (1867) and *The Negro's Origin* (1869). Henry Tanner was a pupil of Thomas Eakins, in Philadelphia, and of J. P. Laurens and Benjamin Constant in Paris, where he lived thereafter. He first exhibited at the Salon in 1895. Examples of his work may be seen at the Philadelphia (Pa.) Museum of Art; Los Angeles county museums; Art Institute of Chicago (Ill.); Metropolitan Museum of Art, New York city; and other public collections. He was a knight of the Legion of Honour and a member of several painters' societies. Tanner died in Paris on May 25, 1937.

TANNHÄUSER (TANHUSER), German minnesinger of the 13th century, who lived for a time at the court of Frederick II, duke of Austria. After Frederick's death he was received at the court of Otto II, duke of Bavaria, but he spent much time in wandering about Germany. He also went as a crusader to the Holy Land. His poems belong to the decadence of the minnesong, and combine a didactic display of learning with descriptions of peasant life. His adventurous life led him to be identified, in the popular imagination, with the knight Tannhäuser who, after many wanderings, comes to the Venusberg, or Hörselberg, near Eisenach. He enters the cave where the Lady Venus—the Frau Hulda of German folklore—holds her court, and abandons himself to a life of sensual pleasure. By and by he is overcome by remorse and, invoking the aid of the Virgin Mary, he obtains permission to return for a while to the outer world. He then goes as a pilgrim to Rome and entreats Pope Urban to secure for him the forgiveness of his sins. The pope declares it is as impossible for him to be pardoned as for the staff he has in his hand to blossom. Tannhäuser departs in despair and returns to the Venusberg. In three days the staff begins to put forth green leaves, and the pope sends messengers in all directions in search of the penitent, but he is never seen again.

This legend was at one time widely known in Germany, and as late as 1830 it survived in a popular song at Entlebuch in Switzerland, a version of which was given by Ludwig Uhland in his *Alten hoch- und niederdeutschen Volkslieder* (1844). Among the attendants of Hulda was the faithful Eckhart, and in the preface to the *Heldenbuch* he is said to sit before the Venusberg, and to warn passers-by of the dangers to which they may be exposed if they linger in the neighbourhood. The legend was reproduced by several modern German poets, and by Richard Wagner in the famous music drama.

TANNIN (TANNIC ACID), the generic name for a widely disseminated group of plant products, so named from their property of converting rawhide into leather (*q.v.*). They are soluble in water, and their solutions, which have an acid reaction and an astringent taste, are coloured dark blue or green by iron salts, a property utilized in the manufacture of ink (*q.v.*). Tannins occur in the roots, wood, bark, leaves, or fruit of many plants as normal physiological products. They also occur to the extent of 45%–65% in galls (*q.v.*), pathological growths on species of oak and sumac resulting from the attack of an insect.

Tannins may be classified into two main groups depending upon the products formed by boiling with mineral acids. Hydrolyzable tannins yield water-soluble products such as gallic acid $(HO)_3C_6H_2.CO_2H$, protocatechuic acid $(HO)_2C_6H_3.CO_2H$, and sugars. Under similar treatment, condensed tannins, by far the larger group, form insoluble precipitates called "tanners reds" or phlobophenes.

Gallotannin or common tannic acid is the best known of the hydrolyzable tannins. It is obtained from Chinese or Aleppo galls by extraction with water or organic solvents. When pure, it is a slightly yellow or tan amorphous powder or mass. It is very soluble in water, less so in alcohol and practically insoluble in ether. Hydrolysis produces gallic acid and glucose. Aleppo galls yield, in addition to gallic acid, some ellagic acid, a constituent also of myrobalan, divi-divi, algarobilla and valonia tannins. Tara, the pods from *Caesalpinia tinctoria,* a plant indigenous to Peru, contains 40%–55% of a gallotannin similar to that from galls and has become an important source for refined tannin and gallic acid. The chestnut oak (*Quercus prinus*) yields a hydrolyzable tannin important in leather manufacture.

Among the important condensed tannins are the extracts from the wood or bark of quebracho, mangrove and wattle. The structures of these tannins are uncertain, but many workers believe them to be related to the flavan catechin found in gambier. Refined analytical methods have shown that many natural tannins are mixtures of several closely related substances.

Uses.—Besides their principal application in the manufacture of leather, tannins find use as a constituent to reduce the viscosity of drilling mud for oil wells, in boiler water to prevent scale formation and in the clarification of wine and beer. Tannic acid is employed as a mordant in the dyeing of cotton with basic dyes. Tannic acid from galls is listed in the *British Pharmacopoeia* (1953) and in the *National Formulary of the United States* (1955). Because of its styptic and astringent properties, it has been used in the treatment of tonsillitis, pharyngitis, hemorrhoids and various skin eruptions. The use of tannic acid in the treatment of burns, formerly widely accepted, has become less popular. Tannic acid has been administered internally to check diarrhea and intestinal bleeding, and also as an antidote for metallic, alkaloidal and glycocidal poisons with which it forms insoluble precipitates.

(V. H. W.)

TANNING, a term describing the conversion of natural skins into leather. Modern tannage may be (1) vegetable tanning; (2) mineral tanning, principally with compounds of chromium or aluminum; (3) combination mineral and vegetable tanning; (4) oil tanning; *i.e.*, chamois leather. *See* LEATHER.

TANNU TUVA: *see* TUVA.

TANSY, the name applied to the species of the genus *Tanacetum* of the Compositae family, but most frequently to the common tansy (*T. vulgare*), a perennial herb, native to Europe, that has been widely grown both as a garden ornamental and for medicinal purposes. It long ago escaped from cultivation and is now a common weed over much of the United States. Formerly the leaves were used extensively as a seasoning in various dishes and by the medical profession for its tonic and stimulant properties. By mid-20th century it was little used although it could still be found in gardens as an ornamental plant. (J. M. BL.)

TANTA, a town of lower Egypt, in a central position nearly midway between the two main branches of the Nile, and converging point of several railways traversing the delta in all directions. Pop. (1956 est.) 164,800. It is the capital of the rich province of Gharbia, and is noted for its fairs and Moslem festivals.

TANTALUM (symbol Ta, atomic number 73, atomic weight 180.95) was discovered by A. G. Ekeberg in 1802. One stable form, Ta^{181}, and radioactive isotopes of mass numbers 180 and 182 are known. The electron arrangement in the unfilled outer orbits (O and P) is: $5s^2$, $5p^6$, $5d^3$, $6s^2$. Tantalum is always found associated with columbium (*q.v.*) in its ores and this resulted in confusion on the part of the early investigators until J. C. G. de Marignac, in 1866, developed a method for the separation of the two elements, a method which has become classical and which is of great commercial value. The important minerals are tantalite, $Fe(TaO_3)_2$, and columbite, $Fe(CbO_3)_2$, found in commercial quantities in Australia, Brazil, Belgian Congo and South Dakota. Of less importance is the mineral microlite $(6CaO.3Ta_2O_5.CbOF_3)$ found in New Mexico. These minerals may carry other elements such as titanium, tin, tungsten and manganese.

Separation.—The pulverized ore is fused in iron pots with sodium hydroxide, which converts the tantalum and columbium into sodium tantalate and sodium columbate, compounds which are insoluble in water if some free alkali is present. At the same time compounds of iron, manganese, etc., which are soluble in

hydrochloric acid are formed. The fused mass is crushed and treated with water and most of the free alkali is removed by decantation. The black residue is digested with hot hydrochloric acid to dissolve the iron and manganese compounds and to react with the sodium tantalate and columbate to form tantalic and columbic acids. These are washed by decantation and dissolved in hydrofluoric acid. Sufficient potassium fluoride is added to the solution to form the double fluorides K_2TaF_7 and $K_2CbOF_5.H_2O$. The concentration of the solution is adjusted so that it is nearly saturated with the tantalum salt when hot (90° C.). On cooling this salt crystallizes out in the form of fine needles, leaving the columbium and most of the impurities in solution. This method of separation was first used by Marignac and its efficiency is the result of the relative solubilities of the potassium double fluorides of tantalum, titanium and columbium. In the order given the solubilities are 5 g., 12 g. and 77 g. per litre at room temperature. The tantalum salt can be purified further by recrystallization from water containing a small amount of hydrofluoric acid, and this potassium tantalum fluoride is used in the preparation of all other compounds of tantalum and the metal itself.

Pure ductile tantalum was made by Werner von Bolton in 1905. The double fluoride was heated with sodium in evacuated tubes to bring about the reaction $K_2TaF_7+5Na=2KF+5NaF+Ta$. The washed, finely divided metal powder was pressed into sticks which were melted down by drawing an arc between them and a water-cooled table within a vacuum furnace. The fused buttons were quite limited in size but could be worked into rod and fine wire. In 1922 C. W. Balke perfected a process whereby tantalum bars weighing up to ten pounds might be produced. The double fluoride is electrolyzed in iron pots provided with graphite anodes. The current keeps the bath liquid and deposits the metal in the form of small crystals. When the pot is full the electrolytic mass is pulverized and the salt is separated from the heavy tantalum powder with an air blast. Final cleaning is done chemically to give a tantalum powder of high purity. This is pressed into bars which are sintered in vacuum furnaces at a temperature not far below the melting point of the metal (2,996° C.). The bar is heated by its own resistance to the passage of an electric current. These bars are very ductile and can be worked into sheet, rod and wire. This is done at room temperature, since the hot metal absorbs large volumes of the common gases and becomes brittle. Tantalum resembles but is somewhat darker than platinum in colour and its specific gravity is 16.6. It is outstanding in its resistance to the action of acids and corrosive chemicals except hydrofluoric acid, concentrated sulphuric and phosphoric acids above 175° C., and solutions of the strong alkalies.

Applications.—Tantalum was first used as a filament in electric lamps, but for this purpose it was soon replaced by tungsten. Its first extensive use was in the manufacture of electrolytic rectifiers. These (trade name "Balkite") utilize the electrolytic valve action of tantalum, which allows an electric current to pass in one direction only when immersed in acid. It is used in electronic tubes. Large quantities of sheet tantalum are used in the construction of chemical equipment for use in handling corrosive gases and liquids. Heat exchangers, evaporators, condensers and acid absorbers are built up from sheet by a special process of electric welding. Tantalum produces minimal foreign-body reactions in the human body and is, therefore, used in nerve and bone surgery with great success.

Compounds of Tantalum.—Tantalum is usually pentavalent but in some compounds its valence can be two, three or four. The pentoxide, Ta_2O_5, is white in colour and is obtained by heating the metal in air or oxygen or by the ignition of tantalic acid, $HTaO_3.xH_2O$. The latter is precipitated by the addition of ammonia to solutions of the alkali double fluorides, by the addition of hydrochloric or nitric acid to solutions of the soluble tantalates or by the action of water on tantalum pentachloride. This acid gives rise to a large number of tantalates such as $4K_2O.3Ta_2O_5.16H_2O$ and $7Cs_2O.6Ta_2O_5.38H_2O$. Tantalates are most easily made by fusion of the oxide with the carbonates or hydroxides of the alkali metals. The addition of hydrogen peroxide to solutions of the tantalates produces pertantalates of which potassium pertantalate, $K_3TaO_8.\frac{1}{2}H_2O$, is typical.

Anhydrous tantalum pentafluoride, TaF_5, can be made by the direct action of fluorine on tantalum in the form of hydroscopic prisms (melting point 97° C., boiling point 229° C.). The tantalum fluoride, formed by the solution of the metal or acid in hydrofluoric acid, is really the acid H_2TaF_7, which forms many double fluorides with the fluorides of other metals. Tantalum pentachloride, $TaCl_5$, is made by the action of chlorine on heated tantalum or by the action of chlorine and the vapours of sulphur monochloride on the heated oxide. It is a white crystalline solid (melting point 211° C., boiling point 241.6° C.). Tantalum carbide, TaC, made by the direct union of the elements or by the action of carbon on the oxide, is a very hard yellow crystalline mass which is used in the manufacture of hard carbide tools for the machining of steel (*see* CARBIDES).

TANTALUS, in Greek legend, son of Zeus or Tmolus and Pluto (Wealth), daughter of Himantes, the father of Pelops and Niobe. He was the traditional king of Sipylus in Lydia (or of Phrygia), and was the intimate friend of Zeus and the other gods, to whose table he was admitted. But he abused the divine favour by revealing to mankind the secrets he had learned in heaven (according to the historian Diodorus Siculus), or by killing his son Pelops and serving him up to the gods at table, in order to test their power of observation (according to Ovid). Another story, by Pindar, was that he stole nectar and ambrosia from heaven and gave them to men. According to others, Pandareus stole a golden dog which guarded the temple of Zeus in Crete, and gave it to Tantalus to take care of. But, when Pandareus demanded the dog back, Tantalus denied that he had received it. Therefore, Zeus turned Pandareus into a stone, and flung down Tantalus with Mt. Sipylus on top of him.

The punishment of Tantalus in the lower world was famous. He stood up to his neck in water, which flowed from him when he tried to drink it; and over his head hung fruits which the wind wafted away whenever he tried to grasp them (*Odyssey*). This myth is the origin of the English word "tantalize." Another story is that a rock hung over his head ready to fall and crush him (Euripides in *Orestes*). The sins of Tantalus were visited upon his descendants, the Pelopidae. Ancient historical reminiscences and natural phenomena, especially volcanic catastrophes, are at the bottom of the legend. The tomb of Tantalus on Mt. Sipylus was pointed out in antiquity, and was identified by C. F. Texier with the great cairn beneath Old Magnesia; but Sir W. M. Ramsay inclined to a remarkable rock-cut tomb beside Magnesia.

The story of Tantalus is an echo of a semi-Greek kingdom, which had its seat at Sipylus, the oldest and holiest city of Lydia, the remains of which are still visible. There was a tradition in antiquity that the city of Tantalus had been swallowed up in a lake on the mountain; but the legend may, as Ramsay thought, have been suggested by the vast ravine which yawns beneath the acropolis. J. Hylén considered the story of the thirst of Tantalus in the underworld to be the result of the Orphic interpolator in the Nekyia of the *Odyssey*, and the Pandareus story to be an innovation of the Alexandrine poets. The essay contains a copious list of authorities and a history of the legend. According to V. Henry, Tantalus is the sun. His betrayal of the secrets of the gods refers to the sun's unveiling the secrets of heaven; the slaying of Pelops denotes the going down of the sun. (*See* PELOPS.)

TANTIA TOPI (*c.* 1819–1859), rebel leader during the Indian Mutiny, was a Mahratta Brahman in the service of Nana Sahib. He instigated the massacre of Cawnpore, and commanded at the battle of Bithur, where he was defeated by Gen. H. Havelock. With the aid of the Gwalior contingent he pressed Gen. C. A. Windham hard at Cawnpore on Nov. 27–28, 1857, but was defeated by Sir Colin Campbell on Dec. 6. Together with the rani of Jhansi he was besieged by Sir Hugh Rose in the Jhansi

fort, but escaped and collected a force of 20,000 men which Sir Hugh defeated without relaxing the siege. This was the decisive action of the campaign in central India, and Tantia Topi was obliged to seek refuge in the jungles of Rajputana and Bundelkhand, where he was taken by Major Meade, condemned and executed on April 18, 1859. He was the only rebel leader in the Mutiny who showed any conspicuous military ability. *See* INDIAN MUTINY.

TANZANIA, UNITED REPUBLIC OF. An independent sovereign state of east central Africa, within the Commonwealth of Nations, consisting of the republics of Tanganyika and Zanzibar. Pop. (1963 est.) 10,123,000 (Tanganyika 9,798,000, Zanzibar 325,000). Of the total area of 362,844 sq.mi. (939,767 sq.km.), Tanganyika comprises 361,800 sq.mi. and Zanzibar and Pemba islands 1,044 sq.mi.; Zanzibar Island lies about 20 mi. (32 km.) off the coast of Tanganyika. The new state came into existence in April 1964 under an act of union signed by the presidents of Tanganyika and Zanzibar and later ratified by the National Assembly of Tanganyika and the Revolutionary Council of Zanzibar. It was subsequently announced that until a constituent assembly had adopted a constitution (proposals for which were to be made by a special commission), the new republic would be governed in accordance with the constitution of Tanganyika, which would be modified to provide Zanzibar with a separate local legislature and executive. The powers exercised by these bodies would, however, be limited to certain internal matters; *i.e.,* those not reserved to the Parliament of the united republic and its executive. These reserved powers would include foreign affairs, defense, police, citizenship, immigration, and external trade. The president of Tanganyika became head of the united republic, and the president of Zanzibar was appointed first vice-president and executive head of Zanzibar. It was further agreed that the existing laws of Tanganyika would have validity in both countries, subject to such amendments as might be found desirable. *See* also TANGANYIKA; ZANZIBAR.

T'AO CH'IEN (T'AO YUAN-MING) (*c.* 365–427), Chinese poet and recluse, was born into a gentry family that had fallen on hard times. When he was about 20, he took a minor official post and for the next ten years was in the service of one or another of the ambitious generals who were threatening the moribund Chin dynasty. In 405, after a brief term as magistrate of P'engts'e, he retired from public life to make a precarious living as a farmer. On more than one occasion crop failure brought him and his family to the verge of starvation. On leaving his last post he had written, "My instinct is all for freedom and will not brook discipline or restraint. Hunger and cold may be sharp, but this going against myself really sickens me. Whenever I have been involved in official life I was mortgaging myself to my mouth and belly." He had no more dealings with officialdom but stuck to the life of poverty and hardship, which he preferred to the rigours of respectability. At the time of his death he was known chiefly as a recluse and an eccentric. His poetry was not much appreciated before the 8th century, but modern critics regard him as the most important poet of his period. The taste of his Six Dynasties contemporaries was for an elaborate and artificial poetry; T'ao Ch'ien's is simple and straightforward, with a minimum of artifice. It deals with country pursuits and his essentially Taoist philosophy of life and death.

T'ao the Hermit: Sixty Poems was translated and annotated with an introduction by William Acker (1952); *Poems* was translated by Lily Pao-hu Chang and Marjorie Sinclair (1953).

See J. R. Hightower, "The *fu* of T'ao Ch'ien," *Harvard Journal of Asiatic Studies,* 17:169–230 (June 1954). (J. R. HR.)

TAOISM has been an integral part of Chinese life and thought for 2,000 years. Like Confucianism (*q.v.*), it has influenced every aspect of Chinese culture, whether philosophy, religion, art, literature, or government. Throughout Chinese history, it has paralleled Confucianism, reinforcing, supplementing, and criticizing it, and it helped shape the development and transformation of Buddhism in China. In a true sense every Chinese is a Taoist. While Confucianism emphasizes social order and an active life, Taoism concentrates on individual life and tranquillity. Though this suggests that Taoism plays a secondary role, the fact is that in its advocacy of individuality, spiritual freedom, naturalness, simplicity, religious mysticism, *laissez faire* in government, and the transcendental ideal in art, it is as important as Confucianism in Chinese tradition.

The name "Taoist School" was not mentioned until the 1st century B.C., but the movement must have been developing for centuries before that. Tradition says that ancient philosophical schools emerged from government offices, and Taoism in particular from that of the historian. This theory may have been influenced by the fact that Lao-tzu (*q.v.*), traditionally considered to be the founder of Taoism, was a curator of historical documents. The deeper meaning of the theory, however, is that Taoism arose in response to actual historical situations. In the 6th century B.C. feudalism in China was beginning to crumble. In the transition to a new age, society was beset with political disorder, economic chaos, and moral decay. For several centuries each of the "100 schools" of philosophy offered its own *tao* (literally, "way") as a solution. The *tao* offered by Lao-tzu and his followers was so unusual and so challenging that their movement alone came to be known as the Taoist School, *Tao-chia.*

Taoism is not a system of purely quiet contemplation or idle speculation. It is a philosophy offering a practical way of life. Later its teachings came to be utilized in the popular religion called *Tao-chiao.* In the Chinese tradition the two have been separate, but in the West they have often been confused under the name Taoism.

PHILOSOPHICAL TAOISM

The origin of Taoism as a philosophy is obscure. The term *tao* can be traced to the earliest Chinese classics, and it is a basic term in all ancient Chinese philosophical schools, including Confucianism. But it was in Lao-tzu, Yang Chu, Chuang-tzu, the *Huai-nan-tzu,* the Neo-Taoists, and the *Lieh-tzu* that the Taoist philosophy developed.

Lao-tzu.—The fundamental doctrines of early Taoism are embodied in the *Lao-tzu,* also called the *Tao-te ching* (*q.v.*). Whether or not the book is an anthology of the 4th century B.C. (the point is disputed), its basic ideas and passages probably go back to Lao-tzu, two centuries earlier. As the second title indicates, it is a classic on Tao and *te,* the "Way" and its "virtue." Previously the connotation of Tao had been social and moral; in the *Lao-tzu* it connotes for the first time the metaphysical. Tao "exists before heaven and earth." It is the "mother" and "ancestor" of all things. It is their "storehouse." It is at once their principle of being and their substance. "All things depend on it for life." It is One, everlasting, and unchangeable; it "operates everywhere and is free from danger." It is "invisible," "inaudible," "vague and elusive," but there is in it the "form" and the "essence." It is so absolute that it cannot be described; it "has no name." Furthermore, it is "nonbeing." The last idea, which appears to be nihilistic, simply means that Tao is prior to and above all things.

In its operation Tao is characterized by *wu-wei* (literally "no action"), which really means taking no unnatural action. It means spontaneity, noninterference, letting things take their own course. Tao "takes no action" but "supports all things in their natural state," and in this way "all things will transform spontaneously." As things arise, "Tao does not turn away from them." "It benefits all things but does not compete with them." "Tao invariably takes no action, and yet there is nothing left undone."

When man follows this natural way, he will abide with the one, the eternal, and the whole and will achieve a life of peace, harmony, and enlightenment. In dealing with things, he will "produce them but not take possession of them." In government he will adopt the policy of *laissez faire,* for "the best rulers are those whose existence is merely known by the people. . . . They complete their work. Nevertheless their people say that they simply follow Nature." Thus the natural way stands in direct opposition to all artificial regulation, organization, and ceremonies. This is the reason why the *Lao-tzu* vigorously attacks all formalities and artificialities. For the same reason it condemns war, taxation, punishment, superficial knowledge, and conventional morality.

The natural way is compared with the ways of water, the female, and the infant; that is, the ways of the weak. Along with weakness, the *Lao-tzu* also advocates humility, contentment, ignorance, submission, knowing where to stop, doing away with desires, accepting disgrace, and the like. This seemingly negative morality is deceptive. After all, "the greatest skill seems to be clumsy, and the greatest eloquence seems to stutter." "There is nothing softer and weaker than water, and yet there is nothing better for attacking hard and strong things."

While the weak seems to be glorified, the strongest stress really is on simplicity. A simple life is one of plainness in which profit is discarded, cleverness abandoned, selfishness eliminated, and desires reduced. It is the life of "perfection which seems to be incomplete" and of "fullness which seems to be empty." It is the life which is "as bright as light but does not dazzle." In short, it is the life of "superior virtue." This life requires all the important moral qualities taught in almost all ethical systems. To Lao-tzu, deep love, frugality, and not daring to be ahead of the world are "three treasures," and because of them one becomes courageous, generous, and a leader of the world. He urges us to love the earth in our dwelling, love what is profound in our hearts, love humanity in our associations, love faithfulness in our words, love order in government, love competence in handling affairs, and love timeliness in our activities. He wants us to maintain steadfast quietude and to be tranquil, enlightened, all embracing, impartial, one with Nature, and in accord with Tao. He teaches us to "benefit all things," to "treat those who are good with goodness" and "also to treat those who are not good with goodness," and to "repay hatred with virtue." He admonishes us not to have ulterior motives, to show or justify ourselves, or to boast, to be proud, to hoard things, or to be extravagant. He advises us to know the subtle and the eternal, but when we do not know anything, to know that we do not know. Virtually all the ingredients of a virtuous life, including the Golden Rule, are included.

In short, the life of superior virtue is one of goodness, enlightenment, peace, and long life.

Yang Chu.—The note of life preservation is particularly strong in Yang Chu (*c.* 440–360 B.C.), who may or may not have been an early Taoist. According to surviving isolated passages of his writings, he would not enter an endangered city, would not join an army, and would not care to exchange a single hair for the profits of the entire world. His main purpose in life was to "preserve life and keep the essence of his being intact." Mencius (*q.v.*) attacked him as an "egoist who denied the special relationship with the ruler." Whether Yang's doctrine actually degenerated to an irresponsible egoism or whether Mencius distorted it is a moot point. Yang Chu's teachings are certainly twisted in the "Yang Chu" chapter of the *Lieh-tzu* (see *Later Developments,* below), where his doctrine of self-preservation is coupled with pessimism on the one hand and hedonism on the other.

Chuang-tzu.—All the basic ideas in Lao-tzu are elaborated in the teachings of Chuang-tzu (*q.v.*). But his system is more than an elaboration; in it Taoism was extended to new dimensions and to a higher degree. To him, existence is not only spontaneity but the state of constant flux and incessant transformation. In Lao-tzu, the major notes are constancy and eternity; change is a minor one. In Chuang-tzu, change is the main theme. He conceives of the universe as a great current in which one state succeeds another in endless procession. No state can be retained, and time cannot be arrested. Life goes on "like a galloping horse." In these constant changes, things transform themselves by themselves, for this is the nature of things. There is no directing agency in this dynamic drama: "if there is a true director, there is no evidence of him."

In this process of rapid change, everything must follow its own nature. It is the nature of the eagle to fly high in the clouds, the nature of the dove to hop from tree to tree. A cypress will last for a thousand years, a mushroom for only a day. Each should live according to its nature. Similarly a man should be contented with his fate and "should not attempt to replace the way of heaven with the way of man." This is the true meaning of *wu-wei.* Though there is a much stronger element of fatalism in Chuang-tzu than in Lao-tzu, following Nature to him does not mean blind submission but rather a realistic recognition of one's own limits.

In the universe, then, there are these individual and continuous transformations, each in its own natural way. Such a universal process of rising and falling, of life and death, inevitably results in a world of differences and inequality, but all these are superficial, relative, often products of subjective points of view. Life and death cause each other, and neither right nor wrong is absolute. This and that, and possibility and impossibility, Chuang-tzu says, mutually produce each other. In reality, "all things are one," for Tao embraces all of them and combines them into a unity. A man of small knowledge will cut things up, discriminate, and make distinctions; a man of great knowledge will be comprehensive, impartial, and see Tao in all its unity. The ideal man will be a "companion with Nature" and a "friend of both life and death." He makes oneness his eternal abode. He abandons selfishness of all descriptions, be it fame, wealth, bias, or subjectivity. He knows his nature, nourishes it, and adapts it to the universal process of transformation. In this way he can "roam the universe" and be "emancipated." Having attained enlightenment through "the light of Nature," he moves in the realm of "great knowledge" and "profound virtue." He is then spiritually free. As the *Chuang-tzu* itself says of him,

> Alone he associates with heaven and earth and spirit, without abandoning or despising things of the world. He does not quarrel over right or wrong and mingles with conventional society. . . . Above, he roams with the Creator, and below he makes friends with those who transcend life and death and beginning and end. In regard to the essential, he is broad and comprehensive, profound and unrestrained. In regard to the fundamental, he may be said to have harmonized all things and penetrated the highest level. However, in his response to change and his understanding of things, his principle is inexhaustible, traceless, dark and obscure, and unfathomable.

In Chuang-tzu, Taoism reached the transcendental and mystical level, but its dynamism and realism became at the same time much stronger. Generally speaking, Chuang-tzu's universe is much more complex than that of Lao-tzu. It involves not only the states of being and nonbeing but also that of neither being nor nonbeing. Lao-tzu's way is directed chiefly to handling human affairs; that of Chuang-tzu aims chiefly at dealing with the universe. Lao-tzu's goal is social and political reform; that of Chuang-tzu is to "travel beyond the mundane world." Every passage of the *Lao-tzu* can be understood in terms of ordinary human experience, but what Chuang-tzu wants is pure experience—that is, identification with the universe. He speaks of "fasting of the mind," in which "the mind is empty to receive all things," and of "sitting down and forgetting everything," in which "the body is abandoned, the intelligence is discarded, one is separated from the body and free from knowledge, and one becomes identical with a great penetration." At the same time, in his emphasis on being true to one's own nature, his philosophy is much more individualistic than that of Lao-tzu. While the notes of mysticism, quietism, and fatalism are stronger, the ultimate goal is preservation of one's original nature and through it absolute spiritual freedom.

From the time of Chuang-tzu till the 2nd century B.C., the Taoist School remained influential. It was the chief rival of both Confucianism and Moism. Followers of Lao-tzu, Yang Chu, and Chuang-tzu probably traveled in slightly different directions, but the main tenets remained prominent and clear. Later they were synthesized in the *Huai-nan-tzu.*

The *Huai-nan-tzu.*—The *Huai-nan-tzu* is an anthology of treatises by Liu An (d. 122 B.C.), prince of Huai-nan, and scholars who gathered around him as his retainers. It represents a combination of Taoist teachings, and as such its originality is negligible. In it, however, the concept of Tao becomes more concrete. Using water as its analogy, the writer describes Tao as a concrete reality, all pervasive, the cause of all things, perfectly weak, taking no unnatural action, and yet bringing all things into completion. Furthermore, cosmogony becomes more elaborate and more definite. "There was a time before the time which was before the beginning," and "there was a time before the time which was before

nonbeing." "Before heaven and earth took shape, there was only undifferentiated formlessness," which was called "the great beginning." In cosmological evolution, Tao originated from vacuity, and vacuity produced the universe, which in turn produced the material forces. The material forces of heaven and earth combined to form *yin* and *yang*, which in their turn give rise to the myriad things. In its broad outline this cosmogony has remained orthodox doctrine not only among Taoist philosophers but also among the later Confucianists.

In its attempt at synthesis, the *Huai-nan-tzu* combines certain non-Taoist elements, such as the Confucian emphasis on learning as a method of self-cultivation and the Legalist emphasis on law in government. In its discussion of the spirit, it even introduces such ideas as immortality on earth and the techniques of breathing, etc., to achieve it, thus paving the way for the later confusion of Taoist philosophy with Taoist popular religion. In spite of this fact, it maintained Taoism at a time when Confucianism had assumed the dominant role in government and thought. In addition, by approaching metaphysics and cosmology in an essentially rational spirit, it prepared for the emergence of rationalistic Neo-Taoism.

Later Developments.—In the 3rd and 4th centuries A.D., Taoism developed in three directions. The first was Neo-Taoism, the most important philosophical development in the history of Taoism, which finds expression in the commentaries on the *Lao-tzu* and the *Book of Changes* by Wang Pi (226–249) and the commentary on the *Chuang-tzu* by Kuo Hsiang (d. 312), who probably appropriated ideas from Hsiang Hsiu (fl. 250). In them, nonbeing is no longer essentially in contrast to being but is the ultimate of all, or pure being (*pen-wu*), the One and the undifferentiated. According to Wang Pi, original nonbeing transcends all distinctions and descriptions. It is the pure being, original substance (*pen-t'i*), and the One in which substance and function are identified. It is always correct because it is in accord with principle. Where Lao-tzu had destiny, Wang would substitute principle, thus anticipating the development in Neo-Confucianism.

Just as Wang Pi went beyond Lao-tzu, so Kuo Hsiang went beyond Chuang-tzu. The major concept is no longer Tao but Nature (*tzu-jan*). Things exist and transform themselves spontaneously, and there is no other reality or agent to cause them. Things exist and transform according to principle, but each and every thing has its own principle. Compared with Wang Pi, Kuo Hsiang emphasizes being rather than nonbeing and the many rather than the one. To Wang Pi, principle transcends things; to Kuo Hsiang, it is immanent in them. To neither of them, however, is the sage one who withdraws into a hermit's life; he lives a life of social and political accomplishment, through taking no unnatural action. Significantly, the greatest sage to them was not Lao-tzu but Confucius.

The second movement was that of the "pure conversation," a way of life expressed in elegant, refined, and carefree conversation, devoid of the vulgarity of politics, earthly ambitions, and worldly values. It lasted from the middle of the 2nd century through the 6th, with Juan Chi (210–263), Hsi K'ang (223–262), and Hsiang Hsiu as outstanding representatives.

The third movement was fatalistic naturalism, represented by the *Lieh-tzu*, a product probably of the 3rd century. Its ideas are all original ingredients of Taoism, but the Taoist doctrine of taking no action has degenerated into complete abandonment of effort, spontaneity is confused with resignation, and having no desire is replaced by hedonism—all negative developments. On the positive side, Tao as the self-caused ultimate reality is much more strongly affirmed, and vacuity in the sense of eliminating desires and renouncing egoism is emphasized. In both of these the *Lieh-tzu* goes beyond Lao-tzu. In being indifferent to life and death and in ignoring the distinction of right and wrong, it pushes skepticism to the extreme; and in considering unceasing transformation as going in cycles according to fate, so that life and death, by their very nature, immediately succeed each other, it gives the doctrine of transformation a peculiar form. In these the *Lieh-tzu* goes beyond Chuang-tzu. In teaching that one should do away with the distinction between oneself and others, avoid a subjective state of mind, be vacuous, pure, and tranquil, and be in accord with Nature, it is essentially Taoistic and may well reflect, or even transmit, the teachings of Lieh-tzu, or Lieh Yü-k'ao (*c.* 450–375 B.C.), whose work had disappeared centuries before.

Influence.—As a philosophy Taoism declined after the 4th century, by which time Taoism and Buddhism had begun mutually to influence each other. In the 3rd and 4th centuries, Buddhist thinkers practised "matching the concepts" of Buddhism and Taoism, as a result of which Buddhists interpreted their philosophy in Taoist terminology while Taoism assimilated Buddhist ideas. Although Taoism eventually became a handmaid of Buddhism, it exercised far greater influence on Buddhist philosophy than vice versa. The major Taoist concepts of being and nonbeing were carried over to Buddhism. Some early Buddhist schools even called themselves "School of Original Nonbeing," "School of Nonbeing of Mind," etc. Like the Neo-Taoists, the Buddhists regarded ultimate reality as transcending all being, names, and forms, and as empty and quiet in Nature.

The greatest influence on Buddhism may be seen in the Chinese development of the Buddhist Meditation School (Ch'an or Zen; *see* ZEN). The Taoist tenets that Tao is everywhere, is indescribable, and can be discovered through enlightenment had a direct bearing on the development of Zen doctrines that the Buddha mind is everywhere, is indescribable by words and inconceivable in thought, and can be realized through enlightenment. The standard ways of Zen enlightenment are "absence of thought," "forgetting one's feelings," and "letting the mind take its own course," literal borrowings from Taoism, especially from Chuang-tzu. Many early Buddhist thinkers were experts in Taoist philosophy, and throughout history many Zen masters have been personal friends of Taoists.

Just as Taoism contributed to the development of Zen in the 7th and 8th centuries, so it contributed to the development of Neo-Confucianism in the 11th (*see* CHINESE PHILOSOPHY), but because of their "way of quietness and nonactivity," the Neo-Confucianists severely attacked the Taoists, and, as a result, Taoism ceased to be a vital philosophical system in the last millennium. As a way of life, however, it has never lost its hold on Chinese culture and society. Its spirit of harmony, simplicity, and peace has been eloquently expressed in Chinese landscape painting, landscape gardening, poetry, tea drinking, etc., and its spirit of naturalism, individualism, and freedom has strongly molded Chinese life.

RELIGIOUS TAOISM

The Way of the Yellow Emperor.—While the philosophy of Taoism was unfolding, a religious current, in progress from time immemorial, was developed by priest-magicians who offered divination and magic as means to inward power, restored youth, superhuman ability, and, most importantly, immortality on earth. Somehow this movement came to be known in the 1st century B.C. as the Way of the Yellow Emperor (Huang-ti) and Lao-tzu, and enjoyed an extensive following. In A.D. 143 Chang Ling, also called Chang Tao Ling, a popular religious leader famous for healing the sick, formally organized the movement and required his many followers to donate five piculs (bushels) of rice (hence the name the Way of Five Piculs of Rice). His followers called him Heavenly Teacher, a title his direct descendants retained until the 1940s.

From the very beginning the Yellow Emperor–Lao-tzu movement was a conglomeration of sorcery, the arts of priest-magicians, and the philosophy of the Yin-Yang School, according to which all things are products of the cosmic negative and positive forces. Gradually it assimilated certain elements of Taoist philosophy. Wei Po-yang (fl. 147–167) combined all these in a coherent system and thus laid the philosophical foundation of the Taoist religion. In his *Ts'an-t'ung-ch'i* ("The Three Ways Unified and Harmonized"), he attempted to synthesize all these ideas for the sake of prolonging life through the practice of alchemy, whereby, it was believed, the two cosmic forces could be harmonized and the vital force (*ch'i*) of the universe concentrated in the human body. His book became the basis of the *Lung-hu* ("Dragon and Tiger") *Scrip-*

ture of unknown date, the *Huang-t'ing* ("Internal and External") *Scripture* (3rd century), and the *Yin-fu* ("Secret Accord") *Scripture* (8th century). Later, Ko Hung (253–333?), also called Pao-p'u-tzu, synthesized Taoist philosophy and Confucian ethics. His chief concern, however, was alchemy to prolong life, and he strongly defended the belief in immortals (*hsien*).

These two philosophers provided religious Taoism with a firm theoretical foundation and an elaborate system of practice. It was K'ou Ch'ien-chih (d. 432) who made it an organized religion, by regulating the ceremonies, fixing the names of deities, and formulating theology. His influence led to its being made a state cult in A.D. 440. State patronage reached its height in the T'ang dynasty (618–906), since when religious Taoism has existed primarily as a religion of the illiterate masses.

Features.—As a religion, Taoism is distinguished by several prominent features, outlined below.

Multiplicity of Gods.—Taoism has a god for almost everything—stars, animate and inanimate things, the whole and parts of the body, ancestors, famous historical beings, ideals, etc. Among these are the Jade Emperor, the Three Pure Ones (Heavenly Honoured Ones Without Form, With Form, and Brahma Form), the Dipper Star, the Great Unit, Gods of Literature, Wealth, Medicine, Kitchen, and Goddess of Mercy (from Buddhism). It worships numerous immortals, has 10 "Heavenly Grottoes," 36 subsidiary "Heavenly Grottoes," and 72 "Blessed Places," where immortals rule and await people to seek the "way." Besides, there are imitations of many Buddhist heavens and hells.

Search for Blessings and Longevity.—Popular Taoism is strongly characterized by piety and devotion, but its chief objectives are earthly blessings—happiness, health, wealth, the begetting of children, and, most of all, longevity. By the 7th century an elaborate system of practices was developed to achieve these blessings and to realize the Three Original Principles of Taoism, namely, Essence, Vital Force, and Spirit. These practices included breath control, baths, diet, mental concentration, sex hygiene, physical exercises, medicine, the use of charms, attempts at disappearance and change of bodily form, and alchemy, especially the effort to transmute mercury into gold. In their pseudoscientific alchemical experiments over the centuries, the Taoists made a number of scientific discoveries and perhaps contributed indirectly to the development of science in Europe.

Superstitions.—The Taoist religion is a rich reservoir of superstitions, including geomancy, fortune-telling, divination, and the use of charms. With modern reforms, these are fast disappearing but not entirely eliminated.

Sects.—Taoism is a wholesale imitation of Buddhism, notably in its clergy, temples, images, ceremonies, and canon. In organization it is generally classified under two schools, the Northern and the Southern. The Southern School, called the True Unity sect, prevailing south of the Yangtze, is traced to the so-called founder Chang Ling but more likely grew up in the 10th century. It emphasizes man's nature—that is, man's spirit or true self—and relies on charms and magic to preserve it. It depends on "self-power" and is idealistic and informal. Its priests are married, live at home, and regard as their head the Heavenly Teacher, who used to reside in the Dragon and Tiger Mountain in central China. He had no influence on the masses and should in no way be called a pope, as he sometimes has been in the West.

The Northern School, called the Complete Unity sect, probably founded in the 13th century, is centred at the White Cloud Temple in Peking. It emphasizes man's life—that is, man's vital force—and relies on medicine and diet to prolong it. It depends on "other-power" and is materialistic and formal. Its priests renounce the home, adopt vegetarianism, and live in temples.

New Societies.—The two schools have been declining since the last half of the 19th century. In their place new societies have grown up, such as the Tao Yuan (Society of the Way), founded about 1920. These are led by laymen, worship deities of all religions, shun superstition, reject the search for earthly immortality but promote charity and moral culture, and, like traditional Taoist sects, sometimes participate in political revolts.

Ethical Teachings.—To most followers, who also follow Confucianism and Buddhism, the Taoist religion is essentially a sanction of ethics. In the two most popular tracts, *The Treatise on Influence and Response* and *The Silent Way of Recompense,* which have been influential for centuries, Confucian moral values (filial piety, loyalty, love, righteousness, and good faith), Buddhist virtues (compassion, kindness to all creatures, and remonstration against all evil deeds), and Taoism's own ethics of patience, simplicity, contentment, and harmony are strongly advocated.

Modern Status.—As a religion of the masses, Taoism has been rapidly fading away, especially since the Communist government came to power in China. Without leadership, financial resources, or recruitment for priests, its future as an organized religion is dim, although private practice, including local temples and shrines in homes, will surely continue. Its superstitions, animism, and idolatry, however, have largely been replaced by social and economic reform activities. Although there is a National Taoist Association in Mainland China, practically all Taoist priests have returned to secular and productive life, and Taoist temples are being used for other purposes. But many elements of the Taoist religion—its fairy tales, magic, aesthetic imagination—are still rich in Chinese folk life, especially in festivals, while the virtuous life and spiritual serenity taught in its religious tracts will continue to influence the Chinese character for a long time to come.

TAORMINA, a town and winter resort on the east coast of Sicily (ancient Tauromenium), in the province of Messina. Pop. (1961) 8,903 (commune). It lies on an abrupt hill 650 ft. (198 m.) above the railway station, and was occupied at least as early as the 8th century B.C. (as the discovery of a Sicel cemetery of that period shows). It was refounded by the Carthaginian Himilco in 397 B.C., after the destruction, by Dionysius the Elder of Syracuse, of neighbouring Naxos. In 392 Dionysius occupied it, and in 358 the exiles from Naxos found a home there. During the 1st Punic War it belonged to the kingdom of Hiero, and after his death it was allied to Rome. During the 1st Servile War it was occupied by Eunous and some of his followers but was taken by the consul Publius Rupilius in 132. It was one of the strongholds of Sextus Pompeius, and after defeating him Augustus made it into a *colonia.* Its marble, wine, and mullets were highly esteemed. In A.D. 902 it was taken and burned by the Saracens; it was retaken in 962, and in 1078 fell to the Normans.

The ancient town perhaps had two citadels; one the hill above the town to the west, now crowned by a medieval castle, the other the hill upon which the theatre was afterward constructed. There are some remains of the city walls. The church of San Pancrazio is built into a temple of the 3rd century B.C., dedicated to Sarapis. Other ruins belong in the main to the Roman period. The theatre, largely hewn in the rock, is of Greek origin but entirely reconstructed. The view is of exceptional beauty, Mt. Etna being seen on the southwest, while to the north are the rugged coast and the mountains of Calabria. There are remains of a smaller theatre (the Odeum), some large cisterns, and a large bath or tank known as the Naumachia. There are also remains of Roman houses, tombs, etc., and fine specimens of Romanesque and Gothic architecture (notably the Palazzo Corvaia).

TAO-TE CHING, also called LAO-TZU, is the basic Taoist writing, a work that has exerted tremendous influence in the Far East for 2,000 years. The title means the "classic of the Way and virtue" (or "and its power"). By the "Way" is meant the natural way of things, the order of Nature. *Tao* is eternal, unchangeable, all pervasive, One, indescribable, and nameless. It is "nonbeing," that is, the source from which all being has come. By "virtue" is meant naturalness, simplicity, and *wu-wei,* or "taking no [unnatural] action."

The book, consisting of from 5,227 to 5,722 words, depending on the edition, is often called the 5,000-character classic. Its 81 chapters are unrelated, repetitious, nearly all rhymed but irregular in literary style, and contain no dialogue, historical event, or

proper noun. Tradition has attributed the work to Lao-tzu (*q.v.*) of the 6th century B.C., whose private name was Tan, but doubts about its authenticity rose as early as the 5th century A.D. Most modern scholars have rejected the tradition. Some, contending that the literary style, the terminology (such as "kings and barons"), and ideas attacking ceremonies and righteousness belonged to the 4th century B.C., have attributed it to a historian of that time, whose private name was also Tan. But since the style, etc., are not confined to that period, the arguments are not conclusive. More and more scholars believe that the basic doctrines were taught by Lao-tzu but that it was a long time after his death, perhaps some time in the 4th century B.C., that the book took form.

There have been more commentaries on the *Tao-te ching* than on any other Chinese classic—about 700 in all, half of which are extant. It is also the most frequently translated; there are more than 40 versions in English. No Chinese or Japanese can be considered educated without some knowledge of this little classic. *See* also TAOISM.

T'AO YUAN-MING: *see* T'AO CH'IEN.

TAPACOLO (TAPACULO), the name given to a group of small to medium-sized birds comprising the passerine family Rhinocryptidae, peculiar to Central and South America. The 25 known species occur chiefly in the Andes, and are most numerous in Chile. A single species (*Scytalopus argentifrons*) occurs as far north as Costa Rica. The several types agree in having large, strong feet, rounded wings and rather short tails which are carried in an upright position. The bill may be either thin and awllike or decidedly thick. Certain modifications of the external nostrils are characteristic of the family. In coloration the plumage is mainly brownish or blackish and, in one form, spotted. The typical tapacolo (*Rhinocrypta lanceolata*), a native of Argentina, is crested and resembles a miniature domestic fowl. The widely distributed, wrenlike genus *Scytalopus* includes more than half of the known forms. All are notably furtive, have weak powers of flight and frequent bushes or undergrowth. Their varied calls are sometimes musical, but consist chiefly of harsh scolding notes.

Tapacolos feed on insects, larvae and related matter. Their nesting habits vary, some forms (*Scytalopus*) making nests on the ground and others in bushes. One species (*Teledromus fuscus*) digs a tunnel. Two white, unmarked eggs comprise a clutch. (E. R. BE.)

TAP DANCE. Tap dancing consists of a special agility of the feet which can be incorporated into any form of dance movement. This agility is used to produce more foot-to-floor contacts than would normally exist. In tap dancing these contacts are made in precise, rhythmical patterns with or without musical accompaniment. They are made audible by attaching small metal plates to the toe and heel of the dancing shoe.

All ethnic groups have retained some form of emphatic foot-to-floor contacts as part of their dance culture. The main sources of tap dancing are the clog dancing of northern England, the reels and flings of Ireland and Scotland, and the rhythmic foot stamping of the African Negro.

The influx to the U.S. of English and Irish labour and of African slaves brought together these basic elements. The 19th-century performers in minstrel shows and showboats stylized and fused them into a form of dance and satire which rapidly became popular. Among the most noted of these performers were Ralph Keeler and Daniel Emmett and the dance team of Lynch and Diamond.

Near the end of the 19th century tap dancing acquired a specific technique of its own. This was divided into two parts known as "buck and wing," and "soft shoe." The buck and wing was very active and fast, was danced in wooden-soled shoes and made loud sounds. Soft shoe was very relaxed and smooth and was danced in soft shoes which made soft sounds. At the turn of the century, George Primrose was the most famous of the soft shoe dancers, while Doyle and Dixon were exponents of the buck and wing.

Between 1910 and 1925 these two varieties of tap dancing merged. Wooden-soled shoes and soft soles largely disappeared, and the modern metal tap made its appearance. The technique remained very much the same and consisted principally of: striking the ball of the foot on the floor with a brushing motion forward, sideward or backward; stepping on the ball of the foot; dropping or scuffing the heel on the floor; scraping the foot over the floor; touching the toe of the foot to the floor; and making contact with any part of the shoe which would produce a sound. Handclaps and slapping of the body were also occasionally used. These steps were combined with a great variety of skillful leg movements and were influenced also by the Spanish *zapateado,* Bavarian *schuhplattler* and many other folk dances.

Some of the tap dancers who began dancing during this period were Pat Rooney, George M. Cohan, the Four Fords, Johnny Boyle, Tom Patricola and the great Bill Robinson, known as "Bojangles." In the 1930s tap was very popular as a medium for chorus dancing and in vaudeville.

Since 1940 tap dancing has added to its basic technique many of the movements of ballet and modern dancing. The footwork has also developed so that an expert tap dancer can make about 64 taps in five seconds and, standing on one leg, can make five tap sounds with a single movement of the supporting leg.

As it became more visually stimulating it was widely used in films and television. Fred Astaire, Gene Kelly, Ray Bolger and Eleanor Powell have been outstanding in these fields, and have added grace, humour and skill to this form of dance. A *Concerto for Tap Dancer* was composed by Morton Gould, to be performed with orchestra. Paul Draper introduced tap dancing in the concert field with classical and jazz music. George Tapps and Rod Strong used groups in this same medium.

There is widespread interest at all age levels in tap dancing and about 50,000 dance schools throughout the United States include it as part of their training. It is estimated that between 4,000,000 and 5,000,000 people study tap dancing. The dance teachers Ned Wayburn and Jack Manning did much to popularize this. The basic steps are comparatively simple to learn, but to become skillful requires years of concentrated study.

With all of its jumps, spins and broad movements, the essence of tap dancing remains the imaginative invention and exact execution of audible rhythmic patterns. It is an art form that has been developed principally in the U.S., and though much changed from its folk origins, it is firmly a part of American culture. (P. DR.)

TAPE RECORDING, MAGNETIC. The process of magnetic tape recording offers one of the most accurate and convenient methods of storing, and later reproducing, any type of information that can be converted into electrical signals. Sounds (*e.g.,* voice and music), electrical data from business machines and metering devices, video signals and the electrical impulses for the automatic control of machinery are examples of the material commonly stored on magnetic tape. Besides the accuracy and convenience of magnetic recording, the ability to erase the storage medium and reuse it many times gives a great economic advantage over other recording methods in many applications.

History.—The idea of storing electrical information by means of magnetized particles was expressed as early as 1888 by Oberlin Smith in an article in *The Electrical World.* However, Valdemar Poulsen, a Danish inventor, was the first to reduce the idea to practice with a recorder which stored the electrical signal on a wire of magnetic steel. He first applied for a Danish patent on this device on Dec. 1, 1898. A working model of the device created great interest at the Paris exposition in 1900, and many of the later applications of magnetic recording were envisioned at that time. Even with this enthusiasm, however, Poulsen could not find financial backers in Europe. In 1903, Poulsen and some American associates formed the American Telegraphone company for the manufacture and sale of an improved version of the device. The telegraphone would record continuously for 30 minutes on a length of piano-wire steel that moved at a speed of 84 in. per second. However, the device did not find wide application.

Following the failure of Poulsen's company, the general public heard little of magnetic recording for several years, but interest continued in many laboratories. W. L. Carlson and G. W. Car-

penter of the U.S. Naval Research laboratory applied for a patent on alternating-current bias for magnetic recording in 1921, and in 1927 J. A. O'Neill received the first U.S. patent for a magnetic tape made by drying a liquid containing magnetic particles on the surface of a strip of paper. A German patent by Fritz Pfleumer of Dresden was issued in 1928 for a similar process. Until this time, the recording medium had been a wire or tape, entirely of or plated with magnetic metals.

During the 1920s Kurt Stille of Germany acquired a number of patents in this field through which he licensed others. One such licensee was Louis Blattner of England, who built a magnetic recording machine to record and synchronize sound with motion pictures. The "Blattnerphone" was used by the British Broadcasting corporation, and later it was bought by the Marconi company. Work on this method of recording progressed in Germany, England and the U.S. during the 1930s. In particular, the Magnetophon company of Germany succeeded in producing a magnetic, film-coated tape, based on Pfleumer's patent, that constituted a low-cost recording medium. During World War II the Magnetophon, using the coated tape, served the Nazi propaganda organizations well, and following the war its principles were copied and improved upon in many countries, with Germany, England and the U.S. the leaders in this work.

Recording Media.—Magnetic materials in almost every possible form are used in one magnetic recording application or another. Drums of nonmagnetic material have their surfaces coated with a magnetic material to record short bursts of information, such as those used in electronic computers and some types of data recording. Cylindrical surfaces of rubber or plastic, impregnated with magnetic particles, are used to record short messages in telephone answering and recording machines. Disks, coated or impregnated with magnetic material and recorded in parallel or spiral tracks, are used in such applications as office dictating machines and electronic computers.

Wire, the first magnetic recording medium, is still used for certain applications, such as portable recorders. Despite improvements in tape, drums, etc., more information can be stored in a given space on wire than on any other medium. However, the fidelity of reproduction, the signal-to-noise ratio, and cross talk (resulting from adjacent recorded layers being wound together on the same spool) are generally poorer than those of tape.

A variety of magnetic tapes have been developed. Some of the early machines used a solid metal tape of magnetic material. A magnetic stainless steel, Vicalloy, consisting of 52% cobalt, 11% vanadium and 37% iron, is particularly useful for both wire and tape. However, a paper or plastic tape coated with a magnetic powder proved to be the most useful form of magnetic recording material and far outstripped the others in variety of application as well as volume produced.

The magnetic material most often used in coating tape is the red form of iron oxide, Fe_2O_3. The way in which this powder is prepared, the impurities deliberately introduced or accidentally present, and the physical size and shape of the particles have much to do with the characteristics obtained. Red iron oxide particles, needle-shaped and roughly one micron ($\frac{1}{1.000.000}$ m.) in length, are widely used. The black oxide, Fe_3O_4, has also been used as a magnetic coating material; it produces a higher signal strength, but is more difficult to erase.

The magnetic powder is thoroughly mixed with a binder, the nature of the latter depending partly on the base material to which it will be applied. The polymeric vinyl chlorides, vinyl acetate, cellulose acetate and ethyl cellulose are commonly used. The solvent employed must not attack the base material or cause adjacent layers of tape to stick to each other when the tape is tightly wound and stored at relatively high temperatures. The object is to obtain a very thin but dense layer of iron oxide on the tape in a very uniform distribution. It must adhere tightly to the base tape, but not to an adjacent layer; it must be flexible, and preferably its characteristics should not change appreciably over many thousands of usages or many years of storage.

The base material may be paper or any one of several plastics. Paper is generally lower in cost and some papers are more stable than plastics in applications where relative humidity and temperature vary widely. However, paper tears easily under tension, and since any irregularity in the thickness of the magnetic layer results in unwanted variations and noise in the recording, even the smoothest paper has a serious disadvantage in performance as compared with plastic, which can be prepared with very smooth surfaces.

Cellulose acetate film can be manufactured at moderate cost with a smooth surface, and it has reasonably good tensile strength, tear resistance and dimensional stability. It is widely used for magnetic tape in thicknesses of about 0.0015 in. Mylar or Terylene (a polyester made from polyethylene terephthalate) is more expensive than cellulose acetate, but has superior characteristics. It is stronger, and more stable under high humidity and temperature conditions. It is also more stable with respect to time, making it possible to store recorded material for many years. It has sufficient strength and stability to be used in films as thin as 0.0005 in., thus greatly reducing the storage space required for a given length of tape. However, a smooth surface is somewhat more difficult to obtain on Mylar than on cellulose acetate.

A typical method of manufacturing tape begins with combining the iron oxide and the binder. The mixture is milled in a large rotating cylinder loaded with steel balls, a process that may require from one to several days. The resulting mixture is an extremely uniform, thick fluid resembling printer's ink. This is filtered to remove any lumps of more than about one micron in diameter.

The paper or plastic film is usually processed in webs up to 20 in. wide. The coating process is done in very clean rooms where only filtered air can enter. The web passes from its roll through a cleaning stage in which both surfaces are cleaned of every trace of dust, lint and other foreign matter; this is accomplished with vacuum suction action, assisted by static removal equipment. The web is then coated with a thin layer of solvent to make the surface receptive to the coating material. When this has had sufficient time to act on the surface, the magnetic coating is applied. This may be done in a fashion similar to engraved-roll printing, in which the amount of material to be applied is metered by the depth of the pattern engraved in the surface of a printing plate. The magnetic mix is applied to the engraved roll and the surface rubbed or scraped to remove the excess. The amount remaining in the engraved pattern is then transferred to the tape web by a rolling action, and the web continues through a drying chamber. When it is dry, the surface may receive a polishing, after which the tape web is ready to be slit and reeled.

The coating remaining on the web is 0.0001 to 0.0004 in. thick when dry, and tolerances of ± 0.000012 in. may be held on the nominal thickness to assure proper performance. For tapes that are used for computers, automatic inspection devices detect any voids in the coating, since these could cause an omission in the stored information, resulting in a serious error.

The tape is slit and wound on reels varying from 3 to 14 in. or more in diameter, depending on the intended application. A 7-in. (outside diameter) reel is common in sound recording work and holds 1,200 to 1,800 ft. depending on the tape thickness.

A 10½-in. reel (2,400 to 3,600 ft.) is widely used by the broadcast industry, and larger reels are frequently used in technical data recording and business-machine operations. Nominal tape widths most commonly used are ¼, ½ and 1 in., with the ¼-in. size having the widest variety of applications.

The Recording Process.—The electrical signal to be recorded is usually applied to the tape by means of a "head" consisting of a coil wound around a core of magnetic iron which has a gap at the point where the tape moves across its surface. The current in the coil produces a magnetomotive force across the gap, magnetizing the particles in the tape. The strength and direction of final magnetization of a particular point on the tape will be determined by the strength and direction of the magnetic field at the moment that point crosses the gap. Thus the tape receives a magnetic record containing direction (north or south pole), amplitude, and linear dimension (along the tape) corresponding to the direction (plus or minus), amplitude and time of the original elec-

trical signal. The exactness of this record depends on a variety of conditions, one of the most important being the original magnetic condition of the tape. There are two conditions which give predictable results. Either the tape should be completely demagnetized before recording, or it should be completely magnetized in one direction or the other. In early wire and tape recording, the latter condition was used. The tape was carried past a permanent magnet so arranged that it brought the magnetic particles to saturation, leaving the tape fully and uniformly magnetized in one direction. The recording head then had a direct-current component added to the signal; this direct-current bias was of the proper direction and amplitude to bring the tape just back to a neutral state. The signal, adding and subtracting from this bias, left the tape magnetized by an amount proportional to its own strength. This is called D.C.-biased recording, and gives comparatively low distortion and good amplitude. However, it has a higher inherent noise level and more distortion than A.C.-biased recording.

In A.C.-biased recording the tape is first completely demagnetized and comes to the recording head in a neutral state. There an alternating current is added to the signal current; it is much higher in amplitude than the signal current, and several times greater than the frequency of the highest-frequency signal to be recorded. In crossing the gap of the recording head the magnetic particles on the tape are subjected to many cycles of the bias current, and leave the head with a magnetization which is proportional to the signal. Very low distortion and high signal-to-noise ratios can be obtained with A.C.-biased recording. For sound and general signal recording, this type of tape recording gives performance superior to that of any other recording method.

For pulse recording, in electronic computers and other digital information devices, distortion is of no importance. It is simply desired to record and later detect the presence of a pulse. In most of these recorders the tape comes to the recording head in a neutral state.

In one system the head may normally carry a current that magnetizes the tape to saturation in one direction. A pulse then carries the current to the other extreme and back again, leaving a short area on the tape magnetized in the opposite direction. This is called two-level recording.

In the other commonly used system the head normally carries no current, and pulses may carry the magnetization of the tape to saturation in either a plus or minus direction. This is called three-level recording.

Losses are encountered in recording through eddy current and resistive and capacitive losses in the windings and core of the head. Space between the head and tape causes very high losses, particularly at high frequencies (short wave lengths). The gap must be very straight and true, and the surfaces in contact with the tape must be very smooth in order to obtain the best possible transfer of the signal pattern onto the tape. Optical polishing methods are commonly used for finishing the surfaces of the gaps and faces of the head that will be in contact with the tape. The gaps used in recording heads vary in length (direction of tape motion) from 0.0002 in., when used also as a reproducing head, to 0.010 in. or more for specialized applications. The tolerances on the trueness of the faces and edges of the gap are usually held to a few millionths of an inch. The width of the cores, and the resulting recorded tracks on the tape, vary from approximately 0.025 in. for certain types of data recording to 0.250 in. for professional audio recording.

Reproduction.—In reproduction, it is usually desired to use the recorded tape to reconstruct the signal, obtaining the same polarity, amplitude and time relationship that originally existed in the recorded signal. To accomplish this, the tape is passed over the same head used in recording, or one similar to it. To reproduce the signal in the proper time relationship, the tape speed must be identical during recording and reproduction.

The magnetized portions of the tape passing over the gap in the reproducing head cause the magnetic flux in the core to change, generating a voltage in the coil. This voltage is proportional to the speed of the tape and the amplitude and frequency of recorded signal. Assuming that the tape speed is constant and that a constant-amplitude signal has been recorded, the reproduced signal will have an amplitude proportional to the frequency of the reproduced signal. This gives a response which rises at the rate of 6 decibels per octave. However, as the length of the waves recorded on the tape become smaller, the gap in the reproducing head spans more and more of a wave length, and a loss in output is encountered which is known as "gap loss." At the frequency where the gap just spans one wave length of the recorded signal, the output is zero. In order to use the tape at as slow a speed as practical and still record high frequencies (short wave lengths of recorded signal), the reproducing head has a gap made as short as the technical progress of the art, and economics, will allow.

The amplifier that obtains its signal from the reproducing head must have a response curve which compensates for the special characteristic of that head, as well as for other losses in the heads and recording process. Some of these losses can be anticipated and compensated for in the recording amplifier. Thus it is necessary to have standards established before tapes can be freely exchanged from one recording machine to another reproducing machine. This has been done to some extent in the audio field, standards being established by industry committees.

In television and data recording and in machine control the frequency response problems are quite specialized and the tapes are usually recorded and reproduced on the same machine or a similar model. Few standards have been established since they are not seriously needed for tape interchanges. In business machine applications the problems are even more specialized. Here, it is not necessary to reproduce exactly what was recorded, but merely to detect and interpret each "bit" or pulse of recorded information. The reproduced signal generally does not resemble the recorded pulse, but does bear a definite relationship to it.

Erasure.—One of the features of magnetic recording which gives it an economic advantage over other recording methods is the ability to erase and reuse the recording medium thousands of times with little or no loss in the quality of recording. Erasure may be accomplished in either of two ways: (1) A reel of tape may be erased by subjecting the whole reel to a strong alternating magnetic field and slowly reducing the field to zero; this is called bulk erasing, and is similar to the method used by a jeweler when demagnetizing a watch, although the equipment must be of a different form to accommodate the large reels of tape. (2) The second method involves using a head, very similar to a recording head, to erase the tape just before it is recorded again; the tape passes over the gap in the head and is subjected to a powerful, high-frequency alternating field which diminishes as the tape passes away from the gap, leaving the tape in a demagnetized or neutral state. Professional sound-recording engineers frequently use both methods to make sure all the previous recording has been removed from a tape before it is used again.

Tape Recording Machines.—A wide variety of mechanisms has been devised to make use of tape recording in many different applications. Since only a small amount of power is required to move the light, flexible tape over the heads for recording or for playing back, it has been possible to make battery- and spring-driven portable mechanisms to record away from established power sources; the smallest of these are pocket-sized. The miniature machines, however, sacrifice some fidelity of reproduction to attain compactness. In particular, it is difficult to attain smooth motion and uniform speed, with the result that "flutter" and change of pitch can be noted in the playback of audio material. Larger portable units are available which give quite high fidelity and are often used for broadcast program recording in the field.

A large market developed in tape recorders for use in the home. These record and play tape at 1.87, 3.75 and 7.5 in. per second, usually on one-half of the width of the $\frac{1}{4}$-in. tape; this doubles the amount of tape available for recording or makes it possible to have two simultaneous channels for stereophonic recording. Prerecorded tapes are available, but the ease with which the amateur can produce acceptable recordings is a strong factor in the popularity of such recording devices. Some machines are designed to record four tracks on a $\frac{1}{4}$-in. tape, allowing even more inten-

sive use of the tape with only a slight further sacrifice in the quality of reproduction.

Sound recorders for special applications are often quite complex. Those used for professional studio recording usually have three motors: one on the supply reel, one on the take-up reel and a third to drive the tape. Extreme care is taken to provide smooth and uniform drive so that reproduction of musical notes will remain in exact pitch with no discernible flutter. Another special application is voice-monitoring service, such as the monitoring of radio channels at an airport. Here, a 2-in. tape is used and a rotating head scans across the tape while the tape moves slowly forward. This makes possible a very long recording time on a comparatively short tape, and a particular passage may be returned to with a minimum of rewinding time.

The same principle, with much elaboration and much higher scanning speeds (1,500 in. per second), is in use for recording television broadcasts. The tape recorders used in data recording are similar to those used in professional audio recording. However, they may utilize wider tapes, and 10, 20 or more tracks may be provided by special multicore heads. In addition, the machines must be capable of starting and stopping the tape in very short intervals of time, and of driving the tape in either direction. The very low inertia of a short piece of tape makes it possible to attain speeds of 15, 30 or 60 in. per second in thousandths of a second. Various fast-acting capstans and brake systems are in use to start and stop the tape, and a slack loop is usually maintained between the reels and the working area by means of servomechanisms. *See* also PHONOGRAPH.

TAPESTRY. Tapestry is popularly assumed to be almost any heavy material, ordinarily wool, hand-woven, machine-woven, or even embroidered, used to cover furniture or walls; and this definition is justified in that it is the older usage, is the definition of the Latin *tapes* and is still reflected in the parallel French derivative noun *tapissier,* "upholsterer."

In the 18th and 19th centuries the definition was narrowed to mean a close-textured plain or twill weave, with the filler, or wefts, so outnumbering the warp yarns as to conceal them completely. By various devices (sword tip, reed, batten or comb) the weft was pushed together so tightly as to create a solid, weft-faced surface.

Thus, in the 20th century, Queen Matilda's Bayeux tapestry of embroidery is considered a hanging, not a tapestry. Tapestry weaving differs from embroidery in that it is freely darned on a bare warp, instead of being wrought upon an already woven material.

There is, however, a strong conviction among textile authorities that the rigid definition of a tapestry as a weft-faced cloth must be amended. They agree that tapestrylike fabrics from the past, such as the mosaiclike twill of Kashmir shawls, the weft-twining of Chilcat blankets and the weft-wrapping of Sumak rugs are, technically, tapestry. Terms like "twill tapestry" and "twined tapestry" are often used to designate these tapestrylike fabrics in weaves other than plain weave.

TECHNIQUE

Tapestry differs from other forms of patterned weaving in that no wefts are carried the full width of the web, except by a very rare accident of design. Each unit of the pattern or the background is woven with a weft of the required colour, which is inserted back and forth only over the spot or section where that colour appears in the pattern. Typically, in plain-cloth technique, the weft passes over and under the warps alternately, and on the return shoot, under, where before it was over, and vice versa. The wefts cover the warps completely, which appear only as more or less marked parallel ridges in the texture—according to their coarseness or fineness.

Where the margin of a colour area is straight and parallel to the warps, a slit is necessarily left, which may be treated in any one of five different ways. First, it may simply be left open, as in the Chinese silk tapestries, which are called *k'ssu,* "cut silk," for that reason. Second, it may be left open on the loom, but sewed up afterward, as in European tapestries from the 14th to the 17th centuries, and also in some later types. Third, the weaver may dovetail his wefts, passing from one side, and from the other, in turn over a common warp. This may be either "comb" dovetailing—single wefts alternating—or "saw-tooth" dovetailing—clusters now from one side, now the other. Dovetailing has the double disadvantage of making the fabric heavier at that point and of blurring the outline. Persian weavers of the 16th century developed a successful variant in silk tapestry rugs, whereby a black outline weft was dovetailed over two warps—one of each of the adjacent colour areas—effectively hiding the coloured wefts in the compacting of the weave, and providing strong clear drawing. The same device is found several centuries earlier in Peru, but if there was a common source, examples from it have not yet been noted.

The fourth treatment—interlocking—was introduced in the Gobelins factory in the 18th century. Here wefts of juxtaposed colour-segments are looped through each other between the two warps which mark, respectively, the margin of each colour. This gives a continuous surface of even weight and was prized by the French weavers because the resultant effect more closely approximated that of painting.

Finally, one curious variant would, in strictest definition, fall outside tapestry, though it starts with the tapestry conception: between every two rows of tapestry-woven wefts is a cloth-woven, full-width shoot which makes the fabric solid. This type could be rigorously classified as a brocaded cloth, but the idea is that of tapestry, with the cloth structure subordinate and the problem solved being one in tapestry weave. The device, rare everywhere, is found in Japan in the 7th and 8th centuries, in east Persia in the 10th century (Moore collection, Yale university), and in medieval Peru.
